Querying statistics columns does not store or update statistics in the `mysql.index_stats` and `mysql.table_stats` dictionary tables under these circumstances:

- When cached statistics have not expired.
- When `information_schema_stats_expiry` is set to 0.
- When the server is started in `read_only`, `super_read_only`, `transaction_read_only`, or `innodb_read_only` mode.
- When the query also fetches Performance Schema data.

`information_schema_stats_expiry` is a session variable, and each client session can define its own expiration value. Statistics that are retrieved from the storage engine and cached by one session are available to other sessions.

Note

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use `InnoDB`. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a `MyISAM` table). To obtain the updated distribution statistics, set `information_schema_stats_expiry=0`.

For `INFORMATION_SCHEMA` tables implemented as views on data dictionary tables, indexes on the underlying data dictionary tables permit the optimizer to construct efficient query execution plans. To see the choices made by the optimizer, use `EXPLAIN`. To also see the query used by the server to execute an `INFORMATION_SCHEMA` query, use `SHOW WARNINGS` immediately following `EXPLAIN`.

Consider this statement, which identifies collations for the `utf8mb4` character set:

```
mysql> SELECT COLLATION_NAME
        FROM INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY
        WHERE CHARACTER_SET_NAME = 'utf8mb4';
```

COLLATION_NAME
utf8mb4_general_ci
utf8mb4_bin
utf8mb4_unicode_ci
utf8mb4_icelandic_ci
utf8mb4_latvian_ci
utf8mb4_romanian_ci
utf8mb4_slovenian_ci
...

How does the server process that statement? To find out, use `EXPLAIN`:

```
mysql> EXPLAIN SELECT COLLATION_NAME
        FROM INFORMATION_SCHEMA.COLLATION_CHARACTER_SET_APPLICABILITY
        WHERE CHARACTER_SET_NAME = 'utf8mb4'\G
```

```
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: cs
    partitions: NULL
       type: const
possible_keys: PRIMARY,name
         key: name
      key_len: 194
         ref: const
        rows: 1
   filtered: 100.00
      Extra: Using index
***** 2. row *****
      id: 1
```

```

select_type: SIMPLE
  table: col
  partitions: NULL
    type: ref
possible_keys: character_set_id
  key: character_set_id
  key_len: 8
  ref: const
  rows: 68
  filtered: 100.00
  Extra: NULL
2 rows in set, 1 warning (0.01 sec)
    
```

To see the query used to satisfy that statement, use `SHOW WARNINGS`:

```

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select `mysql`.`col`.`name` AS `COLLATION_NAME`
        from `mysql`.`character_sets` `cs`
        join `mysql`.`collations` `col`
        where ((`mysql`.`col`.`character_set_id` = '45')
        and ('utf8mb4' = 'utf8mb4'))
    
```

As indicated by `SHOW WARNINGS`, the server handles the query on `COLLATION_CHARACTER_SET_APPLICABILITY` as a query on the `character_sets` and `collations` data dictionary tables in the `mysql` system database.

8.2.4 Optimizing Performance Schema Queries

Applications that monitor databases may make frequent use of Performance Schema tables. To write queries for these tables most efficiently, take advantage of their indexes. For example, include a `WHERE` clause that restricts retrieved rows based on comparison to specific values in an indexed column.

Most Performance Schema tables have indexes. Tables that do not are those that normally contain few rows or are unlikely to be queried frequently. Performance Schema indexes give the optimizer access to execution plans other than full table scans. These indexes also improve performance for related objects, such as `sys` schema views that use those tables.

To see whether a given Performance Schema table has indexes and what they are, use `SHOW INDEX` or `SHOW CREATE TABLE`:

```

mysql> SHOW INDEX FROM performance_schema.accounts\G
***** 1. row *****
Table: accounts
Non_unique: 0
Key_name: ACCOUNT
Seq_in_index: 1
Column_name: USER
Collation: NULL
Cardinality: NULL
Sub_part: NULL
Packed: NULL
Null: YES
Index_type: HASH
Comment:
Index_comment:
Visible: YES
***** 2. row *****
Table: accounts
Non_unique: 0
Key_name: ACCOUNT
Seq_in_index: 2
Column_name: HOST
Collation: NULL
Cardinality: NULL
Sub_part: NULL
    
```

```

        Packed: NULL
        Null: YES
        Index_type: HASH
        Comment:
        Index_comment:
        Visible: YES

mysql> SHOW CREATE TABLE performance_schema.rwlock_instances\G
***** 1. row *****
        Table: rwlock_instances
Create Table: CREATE TABLE `rwlock_instances` (
  `NAME` varchar(128) NOT NULL,
  `OBJECT_INSTANCE_BEGIN` bigint(20) unsigned NOT NULL,
  `WRITE_LOCKED_BY_THREAD_ID` bigint(20) unsigned DEFAULT NULL,
  `READ_LOCKED_BY_COUNT` int(10) unsigned NOT NULL,
  PRIMARY KEY (`OBJECT_INSTANCE_BEGIN`),
  KEY `NAME` (`NAME`),
  KEY `WRITE_LOCKED_BY_THREAD_ID` (`WRITE_LOCKED_BY_THREAD_ID`)
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_0900_ai_ci
    
```

To see the execution plan for a Performance Schema query and whether it uses any indexes, use [EXPLAIN](#):

```

mysql> EXPLAIN SELECT * FROM performance_schema.accounts
        WHERE (USER,HOST) = ('root','localhost')\G
***** 1. row *****
        id: 1
        select_type: SIMPLE
        table: accounts
        partitions: NULL
        type: const
possible_keys: ACCOUNT
        key: ACCOUNT
        key_len: 278
        ref: const,const
        rows: 1
        filtered: 100.00
        Extra: NULL
    
```

The [EXPLAIN](#) output indicates that the optimizer uses the `accounts` table `ACCOUNT` index that comprises the `USER` and `HOST` columns.

Performance Schema indexes are virtual: They are a construct of the Performance Schema storage engine and use no memory or disk storage. The Performance Schema reports index information to the optimizer so that it can construct efficient execution plans. The Performance Schema in turn uses optimizer information about what to look for (for example, a particular key value), so that it can perform efficient lookups without building actual index structures. This implementation provides two important benefits:

- It entirely avoids the maintenance cost normally incurred for tables that undergo frequent updates.
- It reduces at an early stage of query execution the amount of data retrieved. For conditions on the indexed columns, the Performance Schema efficiently returns only table rows that satisfy the query conditions. Without an index, the Performance Schema would return all rows in the table, requiring that the optimizer later evaluate the conditions against each row to produce the final result.

Performance Schema indexes are predefined and cannot be dropped, added, or altered.

Performance Schema indexes are similar to hash indexes. For example:

- They are used only for equality comparisons that use the `=` or `<=>` operators.
- They are unordered. If a query result must have specific row ordering characteristics, include an `ORDER BY` clause.

For additional information about hash indexes, see [Section 8.3.9, “Comparison of B-Tree and Hash Indexes”](#).

8.2.5 Optimizing Data Change Statements

This section explains how to speed up data change statements: `INSERT`, `UPDATE`, and `DELETE`. Traditional OLTP applications and modern web applications typically do many small data change operations, where concurrency is vital. Data analysis and reporting applications typically run data change operations that affect many rows at once, where the main considerations is the I/O to write large amounts of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the industry as ETL, for “extract-transform-load”), sometimes you use other SQL statements or external commands, that mimic the effects of `INSERT`, `UPDATE`, and `DELETE` statements.

8.2.5.1 Optimizing INSERT Statements

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a single connection, send the data for many new rows at once, and delay all index updates and consistency checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)
- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by $\log N$, assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a nonempty table, you can tune the `bulk_insert_buffer_size` variable to make data insertion even faster. See [Section 5.1.8, “Server System Variables”](#).
- When loading a table from a text file, use `LOAD DATA`. This is usually 20 times faster than using `INSERT` statements. See [Section 13.2.7, “LOAD DATA Statement”](#).
- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.
- See [Section 8.5.5, “Bulk Data Loading for InnoDB Tables”](#) for tips specific to `InnoDB` tables.
- See [Section 8.6.2, “Bulk Data Loading for MyISAM Tables”](#) for tips specific to `MyISAM` tables.

8.2.5.2 Optimizing UPDATE Statements

An update statement is optimized like a `SELECT` query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a [MyISAM](#) table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use [OPTIMIZE TABLE](#) occasionally. See [Section 13.7.3.4, “OPTIMIZE TABLE Statement”](#).

8.2.5.3 Optimizing DELETE Statements

The time required to delete individual rows in a [MyISAM](#) table is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the [key_buffer_size](#) system variable. See [Section 5.1.1, “Configuring the Server”](#).

To delete all rows from a [MyISAM](#) table, [TRUNCATE TABLE *tbl_name*](#) is faster than [DELETE FROM *tbl_name*](#). Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See [Section 13.1.37, “TRUNCATE TABLE Statement”](#).

8.2.6 Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by [GRANT](#) statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the [tables_priv](#) and [columns_priv](#) tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

8.2.7 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- If your application makes several database requests to perform related updates, combining the statements into a stored routine can help performance. Similarly, if your application computes a single result based on several column values or large volumes of data, combining the computation into a UDF (user-defined function) can help performance. The resulting fast database operations are then available to be reused by other queries, applications, and even code written in different programming languages. See [Section 24.2, “Using Stored Routines”](#) and [Adding Functions to MySQL](#) for more information.
- To fix any compression issues that occur with [ARCHIVE](#) tables, use [OPTIMIZE TABLE](#). See [Section 16.5, “The ARCHIVE Storage Engine”](#).
- If possible, classify reports as “live” or as “statistical”, where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.
- If you have data that does not conform well to a rows-and-columns table structure, you can pack and store data into a [BLOB](#) column. In this case, you must provide code in your application to pack and unpack information, but this might save I/O operations to read and write the sets of related values.
- With Web servers, store images and other binary assets as files, with the path name stored in the database rather than the file itself. Most Web servers are better at caching files than database contents, so using files is generally faster. (Although you must handle backups and storage issues yourself in this case.)
- If you need really high speed, look at the low-level MySQL interfaces. For example, by accessing the MySQL [InnoDB](#) or [MyISAM](#) storage engine directly, you could get a substantial speed increase compared to using the SQL interface.

Similarly, for databases using the [NDBCLUSTER](#) storage engine, you may wish to investigate possible use of the NDB API (see [MySQL NDB Cluster API Developer Guide](#)).

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replicas to split up the load. To avoid slowing down the source while making backups, you can make backups using a replica. See [Chapter 17, Replication](#).

8.3 Optimization and Indexes

The best way to improve the performance of [SELECT](#) operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the [WHERE](#) clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create an indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. Indexes also add to the cost of inserts, updates, and deletes because each index must be updated. You must find the right balance to achieve fast queries using the optimal set of indexes.

8.3.1 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. This is much faster than reading every row sequentially.

Most MySQL indexes ([PRIMARY KEY](#), [UNIQUE](#), [INDEX](#), and [FULLTEXT](#)) are stored in [B-trees](#). Exceptions: Indexes on spatial data types use R-trees; [MEMORY](#) tables also support [hash indexes](#); [InnoDB](#) uses inverted lists for [FULLTEXT](#) indexes.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in [MEMORY](#) tables) are described in [Section 8.3.9, “Comparison of B-Tree and Hash Indexes”](#).

MySQL uses indexes for these operations:

- To find the rows matching a [WHERE](#) clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows (the most [selective](#) index).
- If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on ([col1](#), [col2](#), [col3](#)), you have indexed search capabilities on ([col1](#)), ([col1](#), [col2](#)), and ([col1](#), [col2](#), [col3](#)). For more information, see [Section 8.3.6, “Multiple-Column Indexes”](#).
- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, [VARCHAR](#) and [CHAR](#) are considered the same if they are declared as the same size. For example, [VARCHAR\(10\)](#) and [CHAR\(10\)](#) are the same size, but [VARCHAR\(10\)](#) and [CHAR\(15\)](#) are not.

For comparisons between nonbinary string columns, both columns should use the same character set. For example, comparing a [utf8](#) column with a [latin1](#) column precludes use of an index.

Comparison of dissimilar columns (comparing a string column to a temporal or numeric column, for example) may prevent use of indexes if values cannot be compared directly without conversion. For a given value such as [1](#) in the numeric column, it might compare equal to any number of values in the string column such as ['1'](#), [' 1'](#), ['00001'](#), or ['01.e1'](#). This rules out use of any indexes for the string column.

- To find the [MIN\(\)](#) or [MAX\(\)](#) value for a specific indexed column [key_col](#). This is optimized by a preprocessor that checks whether you are using [WHERE key_part_N = constant](#) on all key

parts that occur before `key_col` in the index. In this case, MySQL does a single key lookup for each `MIN()` or `MAX()` expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```
SELECT MIN(key_part2),MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable index (for example, `ORDER BY key_part1, key_part2`). If all key parts are followed by `DESC`, the key is read in reverse order. (Or, if the index is a descending index, the key is read in forward order.) See [Section 8.2.1.16, “ORDER BY Optimization”](#), [Section 8.2.1.17, “GROUP BY Optimization”](#), and [Section 8.3.13, “Descending Indexes”](#).
- In some cases, a query can be optimized to retrieve values without consulting the data rows. (An index that provides all the necessary results for a query is called a [covering index](#).) If a query uses from a table only columns that are included in some index, the selected values can be retrieved from the index tree for greater speed:

```
SELECT key_part3 FROM tbl_name
WHERE key_part1=1
```

Indexes are less important for queries on small tables, or big tables where report queries process most or all of the rows. When a query needs to access most of the rows, reading sequentially is faster than working through an index. Sequential reads minimize disk seeks, even if not all the rows are needed for the query. See [Section 8.2.1.23, “Avoiding Full Table Scans”](#) for details.

8.3.2 Primary Key Optimization

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the `NOT NULL` optimization, because it cannot include any `NULL` values. With the `InnoDB` storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key. These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

8.3.3 SPATIAL Index Optimization

MySQL permits creation of `SPATIAL` indexes on `NOT NULL` geometry-valued columns (see [Section 11.4.10, “Creating Spatial Indexes”](#)). The optimizer checks the `SRID` attribute for indexed columns to determine which spatial reference system (SRS) to use for comparisons, and uses calculations appropriate to the SRS. (Prior to MySQL 8.0, the optimizer performs comparisons of `SPATIAL` index values using Cartesian calculations; the results of such operations are undefined if the column contains values with non-Cartesian SRIDs.)

For comparisons to work properly, each column in a `SPATIAL` index must be `SRID`-restricted. That is, the column definition must include an explicit `SRID` attribute, and all column values must have the same `SRID`.

The optimizer considers `SPATIAL` indexes only for `SRID`-restricted columns:

- Indexes on columns restricted to a Cartesian `SRID` enable Cartesian bounding box computations.
- Indexes on columns restricted to a geographic `SRID` enable geographic bounding box computations.

The optimizer ignores `SPATIAL` indexes on columns that have no `SRID` attribute (and thus are not `SRID`-restricted). MySQL still maintains such indexes, as follows:

- They are updated for table modifications ([INSERT](#), [UPDATE](#), [DELETE](#), and so forth). Updates occur as though the index was Cartesian, even though the column might contain a mix of Cartesian and geographical values.
- They exist only for backward compatibility (for example, the ability to perform a dump in MySQL 5.7 and restore in MySQL 8.0). Because [SPATIAL](#) indexes on columns that are not SRID-restricted are of no use to the optimizer, each such column should be modified:
- Verify that all values within the column have the same SRID. To determine the SRIDs contained in a geometry column `col_name`, use the following query:

```
SELECT DISTINCT ST_SRID(col_name) FROM tbl_name;
```

If the query returns more than one row, the column contains a mix of SRIDs. In that case, modify its contents so all values have the same SRID.

- Redefine the column to have an explicit [SRID](#) attribute.
- Recreate the [SPATIAL](#) index.

8.3.4 Foreign Key Optimization

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

8.3.5 Column Indexes

The most common type of index involves a single column, storing copies of the values from that column in a data structure, allowing fast lookups for the rows with the corresponding column values. The B-tree data structure lets the index quickly find a specific value, a set of values, or a range of values, corresponding to operators such as `=`, `>`, `≤`, [BETWEEN](#), [IN](#), and so on, in a [WHERE](#) clause.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See [Chapter 15, The InnoDB Storage Engine](#), and [Chapter 16, Alternative Storage Engines](#). All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

For additional information about column indexes, see [Section 13.1.15, “CREATE INDEX Statement”](#).

- [Index Prefixes](#)
- [FULLTEXT Indexes](#)
- [Spatial Indexes](#)
- [Indexes in the MEMORY Storage Engine](#)

Index Prefixes

With `col_name(N)` syntax in an index specification for a string column, you can create an index that uses only the first `N` characters of the column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a [BLOB](#) or [TEXT](#) column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 767 bytes long for [InnoDB](#) tables that use the [REDUNDANT](#) or [COMPACT](#) row format. The prefix length limit is 3072 bytes for [InnoDB](#) tables that use the [DYNAMIC](#) or [COMPRESSED](#) row format. For [MyISAM](#) tables, the prefix length limit is 1000 bytes.

**Note**

Prefix limits are measured in bytes, whereas the prefix length in [CREATE TABLE](#), [ALTER TABLE](#), and [CREATE INDEX](#) statements is interpreted as number of characters for nonbinary string types ([CHAR](#), [VARCHAR](#), [TEXT](#)) and number of bytes for binary string types ([BINARY](#), [VARBINARY](#), [BLOB](#)). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

If a search term exceeds the index prefix length, the index is used to exclude non-matching rows, and the remaining rows are examined for possible matches.

For additional information about index prefixes, see [Section 13.1.15, “CREATE INDEX Statement”](#).

FULLTEXT Indexes

[FULLTEXT](#) indexes are used for full-text searches. Only the [InnoDB](#) and [MyISAM](#) storage engines support [FULLTEXT](#) indexes and only for [CHAR](#), [VARCHAR](#), and [TEXT](#) columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see [Section 12.10, “Full-Text Search Functions”](#).

Optimizations are applied to certain kinds of [FULLTEXT](#) queries against single [InnoDB](#) tables. Queries with these characteristics are particularly efficient:

- [FULLTEXT](#) queries that only return the document ID, or the document ID and the search rank.
- [FULLTEXT](#) queries that sort the matching rows in descending order of score and apply a [LIMIT](#) clause to take the top N matching rows. For this optimization to apply, there must be no [WHERE](#) clauses and only a single [ORDER BY](#) clause in descending order.
- [FULLTEXT](#) queries that retrieve only the [COUNT\(*\)](#) value of rows matching a search term, with no additional [WHERE](#) clauses. Code the [WHERE](#) clause as [WHERE MATCH\(text\) AGAINST \('other_text'\)](#), without any [> 0](#) comparison operator.

For queries that contain full-text expressions, MySQL evaluates those expressions during the optimization phase of query execution. The optimizer does not just look at full-text expressions and make estimates, it actually evaluates them in the process of developing an execution plan.

An implication of this behavior is that [EXPLAIN](#) for full-text queries is typically slower than for non-full-text queries for which no expression evaluation occurs during the optimization phase.

[EXPLAIN](#) for full-text queries may show [Select tables optimized away](#) in the [Extra](#) column due to matching occurring during optimization; in this case, no table access need occur during later execution.

Spatial Indexes

You can create indexes on spatial data types. [MyISAM](#) and [InnoDB](#) support R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for [ARCHIVE](#), which does not support spatial type indexing).

Indexes in the MEMORY Storage Engine

The [MEMORY](#) storage engine uses [HASH](#) indexes by default, but also supports [BTREE](#) indexes.

8.3.6 Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see [Section 8.3.5, “Column Indexes”](#)).

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

Note

As an alternative to a composite index, you can introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
WHERE hash_col=MD5(CONCAT(val1,val2))
AND col1=val1 AND col2=val2;
```

Suppose that a table has the following specification:

```
CREATE TABLE test (
  id          INT NOT NULL,
  last_name   CHAR(30) NOT NULL,
  first_name  CHAR(30) NOT NULL,
  PRIMARY KEY (id),
  INDEX name (last_name,first_name)
);
```

The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for lookups in queries that specify values in a known range for combinations of `last_name` and `first_name` values. It can also be used for queries that specify just a `last_name` value because that column is a leftmost prefix of the index (as described later in this section). Therefore, the `name` index is used for lookups in the following queries:

```
SELECT * FROM test WHERE last_name='Jones';

SELECT * FROM test
WHERE last_name='Jones' AND first_name='John';

SELECT * FROM test
WHERE last_name='Jones'
AND (first_name='John' OR first_name='Jon');

SELECT * FROM test
WHERE last_name='Jones'
AND first_name >='M' AND first_name < 'N';
```

However, the `name` index is *not* used for lookups in the following queries:

```
SELECT * FROM test WHERE first_name='John';

SELECT * FROM test
WHERE last_name='Jones' OR first_name='John';
```

Suppose that you issue the following `SELECT` statement:

```
SELECT * FROM tbl_name
WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer attempts to use the Index

Merge optimization (see [Section 8.2.1.3, “Index Merge Optimization”](#)), or attempts to find the most restrictive index by deciding which index excludes more rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`.

MySQL cannot use the index to perform lookups if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;

SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve indexed columns, but do not use an index to perform lookups because `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)`.

8.3.7 Verifying Index Usage

Always check whether all your queries really use the indexes that you have created in the tables. Use the `EXPLAIN` statement, as described in [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#).

8.3.8 InnoDB and MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how many rows must be read for each `ref` access
- To estimate how many rows a partial join will produce; that is, the number of rows that an operation of this form will produce:

```
(...) JOIN tbl_name ON tbl_name.key = expr
```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on N/S , where N is the number of rows in the table and S is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the `<=>` comparison operator, `NULL` is not treated differently from any other value: `NULL <=> NULL`, just as `N <=> N` for any other N .

However, for a join based on the `=` operator, `NULL` is different from non-`NULL` values: `expr1 = expr2` is not true when `expr1` or `expr2` (or both) are `NULL`. This affects `ref` accesses for comparisons of the form `tbl_name.key = expr`: MySQL will not access the table if the current value of `expr` is `NULL`, because the comparison cannot be true.

For `=` comparisons, it does not matter how many `NULL` values are in the table. For optimization purposes, the relevant value is the average size of the non-`NULL` value groups. However, MySQL does not currently enable that average size to be collected or used.

For `InnoDB` and `MyISAM` tables, you have some control over collection of table statistics by means of the `innodb_stats_method` and `myisam_stats_method` system variables, respectively. These variables have three possible values, which differ as follows:

- When the variable is set to `nulls_equal`, all `NULL` values are treated as identical (that is, they all form a single value group).

If the `NULL` value group size is much higher than the average non-`NULL` value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-`NULL` values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for `ref` accesses when it should.

- When the variable is set to `nulls_unequal`, `NULL` values are not considered the same. Instead, each `NULL` value forms a separate value group of size 1.

If you have many `NULL` values, this method skews the average value group size downward. If the average non-`NULL` value group size is large, counting `NULL` values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-`NULL` values. Consequently, the `nulls_unequal` method may cause the optimizer to use this index for `ref` lookups when other methods may be better.

- When the variable is set to `nulls_ignored`, `NULL` values are ignored.

If you tend to use many joins that use `<=>` rather than `=`, `NULL` values are not special in comparisons and one `NULL` is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `innodb_stats_method` system variable has a global value; the `myisam_stats_method` system variable has both global and session values. Setting the global value affects statistics collection for tables from the corresponding storage engine. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table's statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method`.

To regenerate `MyISAM` table statistics, you can use any of the following methods:

- Execute `myisamchk --stats_method=method_name --analyze`
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `innodb_stats_method` and `myisam_stats_method`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `innodb_stats_method` or `myisam_stats_method` has at the time. Thus, if you collect statistics using one method, but the system variable is set to the other method when a table's statistics are collected automatically later, the other method will be used.
- There is no way to tell which method was used to generate statistics for a given table.
- These variables apply only to `InnoDB` and `MyISAM` tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

8.3.9 Comparison of B-Tree and Hash Indexes

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the `MEMORY` storage engine that lets you choose B-tree or hash indexes.

- [B-Tree Index Characteristics](#)
- [Hash Index Characteristics](#)

B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the `=`, `>`, `>=`, `<`, `<=`, or `BETWEEN` operators. The index also can be used for `LIKE` comparisons if the argument to `LIKE` is a constant string that does not start with a wildcard character. For example, the following `SELECT` statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%ck%';
```

In the first statement, only rows with `'Patrick' <= key_col < 'Patrickl'` are considered. In the second statement, only rows with `'Pat' <= key_col < 'Pau'` are considered.

The following `SELECT` statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the `LIKE` value begins with a wildcard character. In the second statement, the `LIKE` value is not a constant.

If you use `... LIKE '%string%'` and `string` is longer than three characters, MySQL uses the *Turbo Boyer-Moore algorithm* to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using `col_name IS NULL` employs indexes if `col_name` is indexed.

Any index that does not span all `AND` levels in the `WHERE` clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every `AND` group.

The following `WHERE` clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3

/* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2

/* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5

/* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These `WHERE` clauses do *not* use indexes:

```
/* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2

/* Index is not used in both parts of the WHERE clause */
... WHERE index=1 OR A=10

/* No index spans all rows */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses `LIMIT` to retrieve only some of the rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the `=` or `<=>` operators (but are *very fast*). They are not used for comparison operators such as `<` that find a range of values. Systems that rely on this type of single-value lookup are known as “key-value stores”; to use MySQL for such applications, use hash indexes wherever possible.
- The optimizer cannot use a hash index to speed up `ORDER BY` operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a `MyISAM` or `InnoDB` table to a hash-indexed `MEMORY` table.
- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

8.3.10 Use of Index Extensions

`InnoDB` automatically extends each secondary index by appending the primary key columns to it. Consider this table definition:

```
CREATE TABLE t1 (
  i1 INT NOT NULL DEFAULT 0,
  i2 INT NOT NULL DEFAULT 0,
  d DATE DEFAULT NULL,
  PRIMARY KEY (i1, i2),
  INDEX k_d (d)
) ENGINE = InnoDB;
```

This table defines the primary key on columns `(i1, i2)`. It also defines a secondary index `k_d` on column `(d)`, but internally `InnoDB` extends this index and treats it as columns `(d, i1, i2)`.

The optimizer takes into account the primary key columns of the extended secondary index when determining how and whether to use that index. This can result in more efficient query execution plans and better performance.

The optimizer can use extended secondary indexes for `ref`, `range`, and `index_merge` index access, for Loose Index Scan access, for join and sorting optimization, and for `MIN()`/`MAX()` optimization.

The following example shows how execution plans are affected by whether the optimizer uses extended secondary indexes. Suppose that `t1` is populated with these rows:

```
INSERT INTO t1 VALUES
(1, 1, '1998-01-01'), (1, 2, '1999-01-01'),
(1, 3, '2000-01-01'), (1, 4, '2001-01-01'),
(1, 5, '2002-01-01'), (2, 1, '1998-01-01'),
(2, 2, '1999-01-01'), (2, 3, '2000-01-01'),
(2, 4, '2001-01-01'), (2, 5, '2002-01-01'),
(3, 1, '1998-01-01'), (3, 2, '1999-01-01'),
(3, 3, '2000-01-01'), (3, 4, '2001-01-01'),
(3, 5, '2002-01-01'), (4, 1, '1998-01-01'),
(4, 2, '1999-01-01'), (4, 3, '2000-01-01'),
(4, 4, '2001-01-01'), (4, 5, '2002-01-01'),
(5, 1, '1998-01-01'), (5, 2, '1999-01-01'),
(5, 3, '2000-01-01'), (5, 4, '2001-01-01'),
(5, 5, '2002-01-01');
```

Now consider this query:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'
```

The execution plan depends on whether the extended index is used.

When the optimizer does not consider index extensions, it treats the index `k_d` as only `(d)`. `EXPLAIN` for the query produces this result:

```
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
        type: ref
possible_keys: PRIMARY,k_d
         key: k_d
        key_len: 4
         ref: const
         rows: 5
    Extra: Using where; Using index
```

When the optimizer takes index extensions into account, it treats `k_d` as `(d, i1, i2)`. In this case, it can use the leftmost index prefix `(d, i1)` to produce a better execution plan:

```
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
        type: ref
possible_keys: PRIMARY,k_d
         key: k_d
        key_len: 8
         ref: const,const
         rows: 1
    Extra: Using index
```

In both cases, `key` indicates that the optimizer will use secondary index `k_d` but the `EXPLAIN` output shows these improvements from using the extended index:

- `key_len` goes from 4 bytes to 8 bytes, indicating that key lookups use columns `d` and `i1`, not just `d`.
- The `ref` value changes from `const` to `const,const` because the key lookup uses two key parts, not one.
- The `rows` count decreases from 5 to 1, indicating that `InnoDB` should need to examine fewer rows to produce the result.
- The `Extra` value changes from `Using where; Using index` to `Using index`. This means that rows can be read using only the index, without consulting columns in the data row.

Differences in optimizer behavior for use of extended indexes can also be seen with `SHOW STATUS`:

```
FLUSH TABLE t1;
FLUSH STATUS;
SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01';
SHOW STATUS LIKE 'handler_read%'
```

The preceding statements include `FLUSH TABLES` and `FLUSH STATUS` to flush the table cache and clear the status counters.

Without index extensions, `SHOW STATUS` produces this result:

Variable_name	Value
Handler_read_first	0
Handler_read_key	1
Handler_read_last	0
Handler_read_next	5
Handler_read_prev	0
Handler_read_rnd	0
Handler_read_rnd_next	0

With index extensions, `SHOW STATUS` produces this result. The `Handler_read_next` value decreases from 5 to 1, indicating more efficient use of the index:

Variable_name	Value
Handler_read_first	0
Handler_read_key	1
Handler_read_last	0
Handler_read_next	1
Handler_read_prev	0
Handler_read_rnd	0
Handler_read_rnd_next	0

The `use_index_extensions` flag of the `optimizer_switch` system variable permits control over whether the optimizer takes the primary key columns into account when determining how to use an `InnoDB` table's secondary indexes. By default, `use_index_extensions` is enabled. To check whether disabling use of index extensions will improve performance, use this statement:

```
SET optimizer_switch = 'use_index_extensions=off';
```

Use of index extensions by the optimizer is subject to the usual limits on the number of key parts in an index (16) and the maximum key length (3072 bytes).

8.3.11 Optimizer Use of Generated Column Indexes

MySQL supports indexes on generated columns. For example:

```
CREATE TABLE t1 (f1 INT, gc INT AS (f1 + 1) STORED, INDEX (gc));
```

The generated column, `gc`, is defined as the expression `f1 + 1`. The column is also indexed and the optimizer can take that index into account during execution plan construction. In the following query, the `WHERE` clause refers to `gc` and the optimizer considers whether the index on that column yields a more efficient plan:

```
SELECT * FROM t1 WHERE gc > 9;
```

The optimizer can use indexes on generated columns to generate execution plans, even in the absence of direct references in queries to those columns by name. This occurs if the `WHERE`, `ORDER BY`, or `GROUP BY` clause refers to an expression that matches the definition of some indexed generated column. The following query does not refer directly to `gc` but does use an expression that matches the definition of `gc`:

```
SELECT * FROM t1 WHERE f1 + 1 > 9;
```

The optimizer recognizes that the expression `f1 + 1` matches the definition of `gc` and that `gc` is indexed, so it considers that index during execution plan construction. You can see this using `EXPLAIN`:

```
mysql> EXPLAIN SELECT * FROM t1 WHERE f1 + 1 > 9\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: t1
    partitions: NULL
         type: range
possible_keys: gc
         key: gc
        key_len: 5
         ref: NULL
         rows: 1
    filtered: 100.00
```

Extra: Using index condition

In effect, the optimizer has replaced the expression `f1 + 1` with the name of the generated column that matches the expression. That is also apparent in the rewritten query available in the extended `EXPLAIN` information displayed by `SHOW WARNINGS`:

```
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select `test`.`t1`.`f1` AS `f1`,`test`.`t1`.`gc`
        AS `gc` from `test`.`t1` where (`test`.`t1`.`gc` > 9)
```

The following restrictions and conditions apply to the optimizer's use of generated column indexes:

- For a query expression to match a generated column definition, the expression must be identical and it must have the same result type. For example, if the generated column expression is `f1 + 1`, the optimizer will not recognize a match if the query uses `1 + f1`, or if `f1 + 1` (an integer expression) is compared with a string.
- The optimization applies to these operators: `=`, `<`, `<=`, `>`, `>=`, `BETWEEN`, and `IN()`.

For operators other than `BETWEEN` and `IN()`, either operand can be replaced by a matching generated column. For `BETWEEN` and `IN()`, only the first argument can be replaced by a matching generated column, and the other arguments must have the same result type. `BETWEEN` and `IN()` are not yet supported for comparisons involving JSON values.

- The generated column must be defined as an expression that contains at least a function call or one of the operators mentioned in the preceding item. The expression cannot consist of a simple reference to another column. For example, `gc INT AS (f1) STORED` consists only of a column reference, so indexes on `gc` are not considered.
- For comparisons of strings to indexed generated columns that compute a value from a JSON function that returns a quoted string, `JSON_UNQUOTE()` is needed in the column definition to remove the extra quotes from the function value. (For direct comparison of a string to the function result, the JSON comparator handles quote removal, but this does not occur for index lookups.) For example, instead of writing a column definition like this:

```
doc_name TEXT AS (JSON_EXTRACT(jdoc, '$.name')) STORED
```

Write it like this:

```
doc_name TEXT AS (JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name'))) STORED
```

With the latter definition, the optimizer can detect a match for both of these comparisons:

```
... WHERE JSON_EXTRACT(jdoc, '$.name') = 'some_string' ...
... WHERE JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name')) = 'some_string' ...
```

Without `JSON_UNQUOTE()` in the column definition, the optimizer detects a match only for the first of those comparisons.

- If the optimizer picks the wrong index, an index hint can be used to disable it and force the optimizer to make a different choice.

8.3.12 Invisible Indexes

MySQL supports invisible indexes; that is, indexes that are not used by the optimizer. The feature applies to indexes other than primary keys (either explicit or implicit).

Indexes are visible by default. To control index visibility explicitly for a new index, use a `VISIBLE` or `INVISIBLE` keyword as part of the index definition for `CREATE TABLE`, `CREATE INDEX`, or `ALTER TABLE`:

```
CREATE TABLE t1 (
  i INT,
  j INT,
  k INT,
  INDEX i_idx (i) INVISIBLE
) ENGINE = InnoDB;
CREATE INDEX j_idx ON t1 (j) INVISIBLE;
ALTER TABLE t1 ADD INDEX k_idx (k) INVISIBLE;
```

To alter the visibility of an existing index, use a `VISIBLE` or `INVISIBLE` keyword with the `ALTER TABLE ... ALTER INDEX` operation:

```
ALTER TABLE t1 ALTER INDEX i_idx INVISIBLE;
ALTER TABLE t1 ALTER INDEX i_idx VISIBLE;
```

Information about whether an index is visible or invisible is available from the `INFORMATION_SCHEMA.STATISTICS` table or `SHOW INDEX` output. For example:

```
mysql> SELECT INDEX_NAME, IS_VISIBLE
FROM INFORMATION_SCHEMA.STATISTICS
WHERE TABLE_SCHEMA = 'db1' AND TABLE_NAME = 't1';
```

INDEX_NAME	IS_VISIBLE
i_idx	YES
j_idx	NO
k_idx	NO

Invisible indexes make it possible to test the effect of removing an index on query performance, without making a destructive change that must be undone should the index turn out to be required. Dropping and re-adding an index can be expensive for a large table, whereas making it invisible and visible are fast, in-place operations.

If an index made invisible actually is needed or used by the optimizer, there are several ways to notice the effect of its absence on queries for the table:

- Errors occur for queries that include index hints that refer to the invisible index.
- Performance Schema data shows an increase in workload for affected queries.
- Queries have different `EXPLAIN` execution plans.
- Queries appear in the slow query log that did not appear there previously.

The `use_invisible_indexes` flag of the `optimizer_switch` system variable controls whether the optimizer uses invisible indexes for query execution plan construction. If the flag is `off` (the default), the optimizer ignores invisible indexes (the same behavior as prior to the introduction of this flag). If the flag is `on`, invisible indexes remain invisible but the optimizer takes them into account for execution plan construction.

Index visibility does not affect index maintenance. For example, an index continues to be updated per changes to table rows, and a unique index prevents insertion of duplicates into a column, regardless of whether the index is visible or invisible.

A table with no explicit primary key may still have an effective implicit primary key if it has any `UNIQUE` indexes on `NOT NULL` columns. In this case, the first such index places the same constraint on table rows as an explicit primary key and that index cannot be made invisible. Consider the following table definition:

```
CREATE TABLE t2 (
  i INT NOT NULL,
  j INT NOT NULL,
  UNIQUE j_idx (j)
```

```
) ENGINE = InnoDB;
```

The definition includes no explicit primary key, but the index on `NOT NULL` column `j` places the same constraint on rows as a primary key and cannot be made invisible:

```
mysql> ALTER TABLE t2 ALTER INDEX j_idx INVISIBLE;
ERROR 3522 (HY000): A primary key index cannot be invisible.
```

Now suppose that an explicit primary key is added to the table:

```
ALTER TABLE t2 ADD PRIMARY KEY (i);
```

The explicit primary key cannot be made invisible. In addition, the unique index on `j` no longer acts as an implicit primary key and as a result can be made invisible:

```
mysql> ALTER TABLE t2 ALTER INDEX j_idx INVISIBLE;
Query OK, 0 rows affected (0.03 sec)
```

8.3.13 Descending Indexes

MySQL supports descending indexes: `DESC` in an index definition is no longer ignored but causes storage of key values in descending order. Previously, indexes could be scanned in reverse order but at a performance penalty. A descending index can be scanned in forward order, which is more efficient. Descending indexes also make it possible for the optimizer to use multiple-column indexes when the most efficient scan order mixes ascending order for some columns and descending order for others.

Consider the following table definition, which contains two columns and four two-column index definitions for the various combinations of ascending and descending indexes on the columns:

```
CREATE TABLE t (
  c1 INT, c2 INT,
  INDEX idx1 (c1 ASC, c2 ASC),
  INDEX idx2 (c1 ASC, c2 DESC),
  INDEX idx3 (c1 DESC, c2 ASC),
  INDEX idx4 (c1 DESC, c2 DESC)
);
```

The table definition results in four distinct indexes. The optimizer can perform a forward index scan for each of the `ORDER BY` clauses and need not use a `filesort` operation:

```
ORDER BY c1 ASC, c2 ASC      -- optimizer can use idx1
ORDER BY c1 DESC, c2 DESC   -- optimizer can use idx4
ORDER BY c1 ASC, c2 DESC    -- optimizer can use idx2
ORDER BY c1 DESC, c2 ASC    -- optimizer can use idx3
```

Use of descending indexes is subject to these conditions:

- Descending indexes are supported only for the `InnoDB` storage engine, with these limitations:
 - Change buffering is not supported for a secondary index if the index contains a descending index key column or if the primary key includes a descending index column.
 - The `InnoDB` SQL parser does not use descending indexes. For `InnoDB` full-text search, this means that the index required on the `FTS_DOC_ID` column of the indexed table cannot be defined as a descending index. For more information, see [Section 15.6.2.4, “InnoDB FULLTEXT Indexes”](#).
- Descending indexes are supported for all data types for which ascending indexes are available.
- Descending indexes are supported for ordinary (nongenerated) and generated columns (both `VIRTUAL` and `STORED`).
- `DISTINCT` can use any index containing matching columns, including descending key parts.
- Indexes that have descending key parts are not used for `MIN()`/`MAX()` optimization of queries that invoke aggregate functions but do not have a `GROUP BY` clause.

- Descending indexes are supported for [BTREE](#) but not [HASH](#) indexes. Descending indexes are not supported for [FULLTEXT](#) or [SPATIAL](#) indexes.

Explicitly specified [ASC](#) and [DESC](#) designators for [HASH](#), [FULLTEXT](#), and [SPATIAL](#) indexes results in an error.

8.3.14 Indexed Lookups from TIMESTAMP Columns

Temporal values are stored in [TIMESTAMP](#) columns as UTC values, and values inserted into and retrieved from [TIMESTAMP](#) columns are converted between the session time zone and UTC. (This is the same type of conversion performed by the [CONVERT_TZ\(\)](#) function. If the session time zone is UTC, there is effectively no time zone conversion.)

Due to conventions for local time zone changes such as Daylight Saving Time (DST), conversions between UTC and non-UTC time zones are not one-to-one in both directions. UTC values that are distinct may not be distinct in another time zone. The following example shows distinct UTC values that become identical in a non-UTC time zone:

```
mysql> CREATE TABLE tstable (ts TIMESTAMP);
mysql> SET time_zone = 'UTC'; -- insert UTC values
mysql> INSERT INTO tstable VALUES
      ('2018-10-28 00:30:00'),
      ('2018-10-28 01:30:00');
mysql> SELECT ts FROM tstable;
+-----+
| ts                |
+-----+
| 2018-10-28 00:30:00 |
| 2018-10-28 01:30:00 |
+-----+
mysql> SET time_zone = 'MET'; -- retrieve non-UTC values
mysql> SELECT ts FROM tstable;
+-----+
| ts                |
+-----+
| 2018-10-28 02:30:00 |
| 2018-10-28 02:30:00 |
+-----+
```

Note

To use named time zones such as `'MET'` or `'Europe/Amsterdam'`, the time zone tables must be properly set up. For instructions, see [Section 5.1.14, “MySQL Server Time Zone Support”](#).

You can see that the two distinct UTC values are the same when converted to the `'MET'` time zone. This phenomenon can lead to different results for a given [TIMESTAMP](#) column query, depending on whether the optimizer uses an index to execute the query.

Suppose that a query selects values from the table shown earlier using a [WHERE](#) clause to search the `ts` column for a single specific value such as a user-provided timestamp literal:

```
SELECT ts FROM tstable
WHERE ts = 'literal';
```

Suppose further that the query executes under these conditions:

- The session time zone is not UTC and has a DST shift. For example:

```
SET time_zone = 'MET';
```

- Unique UTC values stored in the [TIMESTAMP](#) column are not unique in the session time zone due to DST shifts. (The example shown earlier illustrates how this can occur.)
- The query specifies a search value that is within the hour of entry into DST in the session time zone.

Under those conditions, the comparison in the `WHERE` clause occurs in different ways for nonindexed and indexed lookups and leads to different results:

- If there is no index or the optimizer cannot use it, comparisons occur in the session time zone. The optimizer performs a table scan in which it retrieves each `ts` column value, converts it from UTC to the session time zone, and compares it to the search value (also interpreted in the session time zone):

```
mysql> SELECT ts FROM tstable
      WHERE ts = '2018-10-28 02:30:00';
```

ts
2018-10-28 02:30:00
2018-10-28 02:30:00

Because the stored `ts` values are converted to the session time zone, it is possible for the query to return two timestamp values that are distinct as UTC values but equal in the session time zone: One value that occurs before the DST shift when clocks are changed, and one value that occurs after the DST shift.

- If there is a usable index, comparisons occur in UTC. The optimizer performs an index scan, first converting the search value from the session time zone to UTC, then comparing the result to the UTC index entries:

```
mysql> ALTER TABLE tstable ADD INDEX (ts);
mysql> SELECT ts FROM tstable
      WHERE ts = '2018-10-28 02:30:00';
```

ts
2018-10-28 02:30:00

In this case, the (converted) search value is matched only to index entries, and because the index entries for the distinct stored UTC values are also distinct, the search value can match only one of them.

Due to different optimizer operation for nonindexed and indexed lookups, the query produces different results in each case. The result from the nonindexed lookup returns all values that match in the session time zone. The indexed lookup cannot do so:

- It is performed within the storage engine, which knows only about UTC values.
- For the two distinct session time zone values that map to the same UTC value, the indexed lookup matches only the corresponding UTC index entry and returns only a single row.

In the preceding discussion, the data set stored in `tstable` happens to consist of distinct UTC values. In such cases, all index-using queries of the form shown match at most one index entry.

If the index is not `UNIQUE`, it is possible for the table (and the index) to store multiple instances of a given UTC value. For example, the `ts` column might contain multiple instances of the UTC value `'2018-10-28 00:30:00'`. In this case, the index-using query would return each of them (converted to the MET value `'2018-10-28 02:30:00'` in the result set). It remains true that index-using queries match the converted search value to a single value in the UTC index entries, rather than matching multiple UTC values that convert to the search value in the session time zone.

If it is important to return all `ts` values that match in the session time zone, the workaround is to suppress use of the index with an `IGNORE INDEX` hint:

```
mysql> SELECT ts FROM tstable
      IGNORE INDEX (ts)
      WHERE ts = '2018-10-28 02:30:00';
```

ts

ts
2018-10-28 02:30:00
2018-10-28 02:30:00

The same lack of one-to-one mapping for time zone conversions in both directions occurs in other contexts as well, such as conversions performed with the `FROM_UNIXTIME()` and `UNIX_TIMESTAMP()` functions. See [Section 12.7, “Date and Time Functions”](#).

8.4 Optimizing Database Structure

In your role as a database designer, look for the most efficient way to organize your schemas, tables, and columns. As when tuning application code, you minimize I/O, keep related items together, and plan ahead so that performance stays high as the data volume increases. Starting with an efficient database design makes it easier for team members to write high-performing application code, and makes the database likely to endure as applications evolve and are rewritten.

8.4.1 Optimizing Data Size

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application can give you a big performance gain. See [Chapter 15, *The InnoDB Storage Engine*](#), and [Chapter 16, *Alternative Storage Engines*](#).

You can get better performance for a table and minimize storage space by using the techniques listed here:

- [Table Columns](#)
- [Row Format](#)
- [Indexes](#)
- [Joins](#)
- [Normalization](#)

Table Columns

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.
- Declare columns to be `NOT NULL` if possible. It makes SQL operations faster, by enabling better use of indexes and eliminating overhead for testing whether each value is `NULL`. You also save some storage space, one bit per column. If you really need `NULL` values in your tables, use them. Just avoid the default setting that allows `NULL` values in every column.

Row Format

- `InnoDB` tables are created using the `DYNAMIC` row format by default. To use a row format other than `DYNAMIC`, configure `innodb_default_row_format`, or specify the `ROW_FORMAT` option explicitly in a `CREATE TABLE` or `ALTER TABLE` statement.

The compact family of row formats, which includes `COMPACT`, `DYNAMIC`, and `COMPRESSED`, decreases row storage space at the cost of increasing CPU use for some operations. If your

workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

The compact family of row formats also optimizes `CHAR` column storage when using a variable-length character set such as `utf8mb3` or `utf8mb4`. With `ROW_FORMAT=REDUNDANT`, `CHAR(N)` occupies $N \times$ the maximum byte length of the character set. Many languages can be written primarily using single-byte `utf8` characters, so a fixed storage length often wastes space. With the compact family of rows formats, `InnoDB` allocates a variable amount of storage in the range of N to $N \times$ the maximum byte length of the character set for these columns by stripping trailing spaces. The minimum storage length is N bytes to facilitate in-place updates in typical cases. For more information, see [Section 15.10, “InnoDB Row Formats”](#).

- To minimize space even further by storing table data in compressed form, specify `ROW_FORMAT=COMPRESSED` when creating `InnoDB` tables, or run the `myisampack` command on an existing `MyISAM` table. (`InnoDB` compressed tables are readable and writable, while `MyISAM` compressed tables are read-only.)
- For `MyISAM` tables, if you do not have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size row format is used. This is faster but may waste some space. See [Section 16.2.3, “MyISAM Table Storage Formats”](#). You can hint that you want to have fixed length rows even if you have `VARCHAR` columns with the `CREATE TABLE` option `ROW_FORMAT=FIXED`.

Indexes

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient. For `InnoDB` tables, the primary key columns are duplicated in each secondary index entry, so a short primary key saves considerable space if you have many secondary indexes.
- Create only the indexes that you need to improve query performance. Indexes are good for retrieval, but slow down insert and update operations. If you access a table mostly by searching on a combination of columns, create a single composite index on them rather than a separate index for each column. The first part of the index should be the column most used. If you *always* use many columns when selecting from the table, the first column in the index should be the one with the most duplicates, to obtain better compression of the index.
- If it is very likely that a long string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see [Section 13.1.15, “CREATE INDEX Statement”](#)). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See [Section 5.1.1, “Configuring the Server”](#).

Joins

- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.
- Declare columns with identical information in different tables with identical data types, to speed up joins based on the corresponding columns.
- Keep column names simple, so that you can use the same name across different tables and simplify join queries. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.

Normalization

- Normally, try to keep all data nonredundant (observing what is referred to in database theory as *third normal form*). Instead of repeating lengthy values such as names and addresses, assign them unique IDs, repeat these IDs as needed across multiple smaller tables, and join the tables in queries by referencing the IDs in the join clause.

- If speed is more important than disk space and the maintenance costs of keeping multiple copies of data, for example in a business intelligence scenario where you analyze all the data from large tables, you can relax the normalization rules, duplicating information or creating summary tables to gain more speed.

8.4.2 Optimizing MySQL Data Types

8.4.2.1 Optimizing for Numeric Data

- For unique IDs or other values that can be represented as either strings or numbers, prefer numeric columns to string columns. Since large numeric values can be stored in fewer bytes than the corresponding strings, it is faster and takes less memory to transfer and compare them.
- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you can avoid parsing the text file to find line and column boundaries.

8.4.2.2 Optimizing for Character and String Types

For character and string columns, follow these guidelines:

- Use binary collation order for fast comparison and sort operations, when you do not need language-specific collation features. You can use the `BINARY` operator to use binary collation within a particular query.
- When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.
- For column values less than 8KB in size, use binary `VARCHAR` instead of `BLOB`. The `GROUP BY` and `ORDER BY` clauses can generate temporary tables, and these temporary tables can use the `MEMORY` storage engine if the original table does not contain any `BLOB` columns.
- If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.
- When you use a randomly generated value as a primary key in an `InnoDB` table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, `InnoDB` can insert and retrieve them faster.
- See [Section 8.4.2.1, “Optimizing for Numeric Data”](#) for reasons why a numeric column is usually preferable to an equivalent string column.

8.4.2.3 Optimizing for BLOB Types

- When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by `InnoDB` or `MyISAM`.
- For a table with several columns, to reduce memory requirements for queries that do not use the BLOB column, consider splitting the BLOB column into a separate table and referencing it with a join query when needed.
- Since the performance requirements to retrieve and display a BLOB value might be very different from other data types, you could put the BLOB-specific table on a different storage device or even a separate database instance. For example, to retrieve a BLOB might require a large sequential disk read that is better suited to a traditional hard drive than to an [SSD device](#).

- See [Section 8.4.2.2, “Optimizing for Character and String Types”](#) for reasons why a binary `VARCHAR` column is sometimes preferable to an equivalent `BLOB` column.
- Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the `MD5()` or `CRC32()` function to produce the hash value.) Since hash functions can produce duplicate results for different inputs, you still include a clause `AND blob_column = long_string_value` in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

8.4.3 Optimizing for Many Tables

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

8.4.3.1 How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have fewer than 12 tables.

MySQL is multithreaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The `table_open_cache` and `max_connections` system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_open_cache` is related to `max_connections`. For example, for 200 concurrent running connections, specify a table cache size of at least $200 * N$, where N is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_open_cache` setting. If `table_open_cache` is set too high, MySQL may run out of file descriptors and exhibit symptoms such as refusing connections or failing to perform queries.

Also take into account that the `MyISAM` storage engine needs two file descriptors for each unique open table. To increase the number of file descriptors available to MySQL, set the `open_files_limit` system variable. See [Section B.3.2.17, “File Not Found and Similar Errors”](#).

The cache of open tables is kept at a level of `table_open_cache` entries. The server autosizes the cache size at startup. To set the size explicitly, set the `table_open_cache` system variable at startup. MySQL may temporarily open more tables than this to execute queries, as described later in this section.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.

- When the cache contains more than `table_open_cache` entries and a table in the cache is no longer being used by any threads.
- When a table-flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables not currently in use are released, beginning with the table least recently used.
- If a new table must be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A `MyISAM` table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any `MyISAM` table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See [Section 13.2.4, “HANDLER Statement”](#).

To determine whether your table cache is too small, check the `Opened_tables` status variable, which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Opened_tables | 2741  |
+-----+-----+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, increase the `table_open_cache` value at server startup.

8.4.3.2 Disadvantages of Creating Many Tables in the Same Database

If you have many `MyISAM` tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

8.4.4 Internal Temporary Table Use in MySQL

In some cases, the server creates internal temporary tables while processing statements. Users have no direct control over when this occurs.

The server creates temporary tables under conditions such as these:

- Evaluation of `UNION` statements, with some exceptions described later.
- Evaluation of some views, such those that use the `TEMPTABLE` algorithm, `UNION`, or aggregation.
- Evaluation of derived tables (see [Section 13.2.11.8, “Derived Tables”](#)).
- Evaluation of common table expressions (see [Section 13.2.15, “WITH \(Common Table Expressions\)”](#)).
- Tables created for subquery or semijoin materialization (see [Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#)).

- Evaluation of statements that contain an `ORDER BY` clause and a different `GROUP BY` clause, or for which the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue.
- Evaluation of `DISTINCT` combined with `ORDER BY` may require a temporary table.
- For queries that use the `SQL_SMALL_RESULT` modifier, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.
- To evaluate `INSERT ... SELECT` statements that select from and insert into the same table, MySQL creates an internal temporary table to hold the rows from the `SELECT`, then inserts those rows into the target table. See [Section 13.2.6.1, “INSERT ... SELECT Statement”](#).
- Evaluation of multiple-table `UPDATE` statements.
- Evaluation of `GROUP_CONCAT()` or `COUNT(DISTINCT)` expressions.
- Evaluation of window functions (see [Section 12.21, “Window Functions”](#)) uses temporary tables as necessary.

To determine whether a statement requires a temporary table, use `EXPLAIN` and check the `Extra` column to see whether it says `Using temporary` (see [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#)). `EXPLAIN` will not necessarily say `Using temporary` for derived or materialized temporary tables. For statements that use window functions, `EXPLAIN` with `FORMAT=JSON` always provides information about the windowing steps. If the windowing functions use temporary tables, it is indicated for each step.

Some query conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a `BLOB` or `TEXT` column in the table. However, the `TempTable` storage engine, which is the default storage engine for in-memory internal temporary tables in MySQL 8.0, supports binary large object types as of MySQL 8.0.13. See [Internal Temporary Table Storage Engine](#).
- Presence of any string column with a maximum length larger than 512 (bytes for binary strings, characters for nonbinary strings) in the `SELECT` list, if `UNION` or `UNION ALL` is used.
- The `SHOW COLUMNS` and `DESCRIBE` statements use `BLOB` as the type for some columns, thus the temporary table used for the results is an on-disk table.

The server does not use a temporary table for `UNION` statements that meet certain qualifications. Instead, it retains from temporary table creation only the data structures necessary to perform result column typecasting. The table is not fully instantiated and no rows are written to or read from it; rows are sent directly to the client. The result is reduced memory and disk requirements, and smaller delay before the first row is sent to the client because the server need not wait until the last query block is executed. `EXPLAIN` and optimizer trace output reflects this execution strategy: The `UNION RESULT` query block is not present because that block corresponds to the part that reads from the temporary table.

These conditions qualify a `UNION` for evaluation without a temporary table:

- The union is `UNION ALL`, not `UNION` or `UNION DISTINCT`.
- There is no global `ORDER BY` clause.
- The union is not the top-level query block of an `{INSERT | REPLACE} ... SELECT ...` statement.

Internal Temporary Table Storage Engine

An internal temporary table can be held in memory and processed by the `TempTable` or `MEMORY` storage engine, or stored on disk by the `InnoDB` storage engine.

Storage Engine for In-Memory Internal Temporary Tables

The `internal_tmp_mem_storage_engine` session variable defines the storage engine for in-memory internal temporary tables. Permitted values are `TempTable` (the default) and `MEMORY`.

The `TempTable` storage engine provides efficient storage for `VARCHAR` and `VARBINARY` columns. Storage of other binary large object types is supported as of MySQL 8.0.13. The `temptable_max_ram` variable defines the maximum amount of RAM that can be occupied by the `TempTable` storage engine before it starts allocating space from disk in the form memory-mapped temporary files or `InnoDB` on-disk internal temporary tables. The default `temptable_max_ram` setting is 1GiB. The `temptable_use_mmap` variable (introduced in MySQL 8.0.16) controls whether the `TempTable` storage engine uses memory-mapped files or `InnoDB` on-disk internal temporary tables when the `temptable_max_ram` limit is exceeded. The default setting is `temptable_use_mmap=ON`.

Note

The `temptable_max_ram` setting does not account for the thread-local memory block allocated to each thread that uses the `TempTable` storage engine. The size of the thread-local memory block depends on the size of the thread's first memory allocation request. If the request is less than 1MB, which it is in most cases, the thread-local memory block size is 1MB. If the request is greater than 1MB, the thread-local memory block is approximately the same size as the initial memory request. The thread-local memory block is held in thread-local storage until thread exit.

Use of memory-mapped temporary files by the `TempTable` storage engine as an overflow mechanism for internal temporary tables is governed by these rules:

- Temporary files are created in the directory defined by the `tmpdir` variable.
- Temporary files are deleted immediately after they are created and opened, and therefore do not remain visible in the `tmpdir` directory. The space occupied by temporary files is held by the operating system while temporary files are open. The space is reclaimed when temporary files are closed by the `TempTable` storage engine, or when the `mysqld` process is shut down.
- Data is never moved between RAM and temporary files, within RAM, or between temporary files.
- New data is stored in RAM if space becomes available within the limit defined by `temptable_max_ram`. Otherwise, new data is stored in temporary files.
- If space becomes available in RAM after some of the data for a table is written to temporary files, it is possible for the remaining table data to be stored in RAM.

If the `TempTable` storage engine is configured to use `InnoDB` on-disk internal temporary tables as the overflow mechanism (`temptable_use_mmap=OFF`), an in-memory table that exceeds the `temptable_max_ram` limit is converted to an `InnoDB` on-disk internal temporary table, and any rows belonging to that table are moved from memory to the `InnoDB` on-disk internal temporary table. The `internal_tmp_disk_storage_engine` setting (removed in MySQL 8.0.16) has no effect on the `TempTable` storage engine overflow mechanism.

Consider using `InnoDB` on-disk internal temporary tables as the `TempTable` overflow mechanism if the `TempTable` storage engine often exceeds the `temptable_max_ram` limit and uses excessive space in the temporary directory for memory-mapped files. This may occur due to use of large internal temporary tables or extensive use of internal temporary tables. `InnoDB` on-disk internal temporary tables are created in session temporary tablespaces, which reside in the data directory by default. For more information, see [Section 15.6.3.5, “Temporary Tablespaces”](#).

When using the `MEMORY` storage engine for in-memory temporary tables, MySQL automatically converts an in-memory temporary table to an on-disk table if it becomes too large. The maximum size of an in-memory temporary table is defined by the `tmp_table_size` or `max_heap_table_size` value, whichever is smaller. This differs from `MEMORY` tables explicitly created with `CREATE TABLE`.

For such tables, only the `max_heap_table_size` variable determines how large a table can grow, and there is no conversion to on-disk format.

Storage Engine for On-Disk Internal Temporary Tables

Starting with MySQL 8.0.16, the server always uses the `InnoDB` storage engine for managing internal temporary tables on disk.

In MySQL 8.0.15 and earlier, the `internal_tmp_disk_storage_engine` variable was used to define the storage engine used for on-disk internal temporary tables. This variable was removed in MySQL 8.0.16, and the storage engine used for this purpose is no longer user-configurable.

In MySQL 8.0.15 and earlier: For common table expressions (CTEs), the storage engine used for on-disk internal temporary tables cannot be `MyISAM`. If `internal_tmp_disk_storage_engine=MYISAM`, an error occurs for any attempt to materialize a CTE using an on-disk temporary table.

In MySQL 8.0.15 and earlier: When using `internal_tmp_disk_storage_engine=INNODB`, queries that generate on-disk internal temporary tables that exceed `InnoDB row or column limits` return `Row size too large` or `Too many columns` errors. The workaround is to set `internal_tmp_disk_storage_engine` to `MYISAM`.

Internal Temporary Table Storage Format

When in-memory internal temporary tables are managed by the `TempTable` storage engine, rows that include `VARCHAR` columns, `VARBINARY` columns, or other binary large object type columns (supported as of MySQL 8.0.13) are represented in memory by an array of cells, with each cell containing a NULL flag, the data length, and a data pointer. Column values are placed in consecutive order after the array, in a single region of memory, without padding. Each cell in the array uses 16 bytes of storage. The same storage format applies when the `TempTable` storage engine exceeds the `temptable_max_ram` limit and starts allocating space from disk as memory-mapped files or `InnoDB` on-disk internal temporary tables.

When in-memory internal temporary tables are managed by the `MEMORY` storage engine, fixed-length row format is used. `VARCHAR` and `VARBINARY` column values are padded to the maximum column length, in effect storing them as `CHAR` and `BINARY` columns.

Previous to MySQL 8.0.16, on-disk internal temporary tables were managed by the `InnoDB` or `MyISAM` storage engine (depending on the `internal_tmp_disk_storage_engine` setting). Both engines store internal temporary tables using dynamic-width row format. Columns take only as much storage as needed, which reduces disk I/O, space requirements, and processing time compared to on-disk tables that use fixed-length rows. Beginning with MySQL 8.0.16, `internal_tmp_disk_storage_engine` is not supported, and internal temporary tables on disk are always handled by `InnoDB`.

When using the `MEMORY` storage engine, statements can initially create an in-memory internal temporary table and then convert it to an on-disk table if the table becomes too large. In such cases, better performance might be achieved by skipping the conversion and creating the internal temporary table on disk to begin with. The `big_tables` variable can be used to force disk storage of internal temporary tables.

Monitoring Internal Temporary Table Creation

When an internal temporary table is created in memory or on disk, the server increments the `Created_tmp_tables` value. When an internal temporary table is created on disk, the server increments the `Created_tmp_disk_tables` value. If too many internal temporary tables are created on disk, consider increasing the `tmp_table_size` and `max_heap_table_size` settings.

Note

Due to a known limitation, `Created_tmp_disk_tables` does not count on-disk temporary tables created in memory-mapped files. By default,

the TempTable storage engine overflow mechanism creates internal temporary tables in memory-mapped files. This behavior is controlled by the `temptable_use_mmap` variable, which is enabled by default.

The `memory/temptable/physical_ram` and `memory/temptable/physical_disk` Performance Schema instruments can be used to monitor TempTable space allocation from memory and disk. `memory/temptable/physical_ram` reports the amount of allocated RAM. `memory/temptable/physical_disk` reports the amount of space allocated from disk when memory-mapped files are used as the TempTable overflow mechanism (`temptable_use_mmap=ON`). If the `physical_disk` instrument reports a value other than 0 and memory-mapped files are used as the TempTable overflow mechanism, the `temptable_max_ram` threshold was reached at some point. Data can be queried in Performance Schema memory summary tables such as `memory_summary_global_by_event_name`. See [Section 26.12.18.10, “Memory Summary Tables”](#).

8.4.5 Limits on Number of Databases and Tables

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. [InnoDB](#) permits up to 4 billion tables.

8.4.6 Limits on Table Size

The effective maximum table size for MySQL databases is usually determined by operating system constraints on file sizes, not by MySQL internal limits. For up-to-date information operating system file size limits, refer to the documentation specific to your operating system.

Windows users, please note that FAT and VFAT (FAT32) are *not* considered suitable for production use with MySQL. Use NTFS instead.

If you encounter a full-table error, there are several reasons why it might have occurred:

- The disk might be full.
- You are using [InnoDB](#) tables and have run out of room in an [InnoDB](#) tablespace file. The maximum tablespace size is also the maximum size for a table. For tablespace size limits, see [Section 15.22, “InnoDB Limits”](#).

Generally, partitioning of tables into multiple tablespace files is recommended for tables larger than 1TB in size.

- You have hit an operating system file size limit. For example, you are using [MyISAM](#) tables on an operating system that supports files only up to 2GB in size and you have hit this limit for the data file or index file.
- You are using a [MyISAM](#) table and the space required for the table exceeds what is permitted by the internal pointer size. [MyISAM](#) permits data and index files to grow up to 256TB by default, but this limit can be changed up to the maximum permissible size of 65,536TB ($256^7 - 1$ bytes).

If you need a [MyISAM](#) table that is larger than the default limit and your operating system supports large files, the `CREATE TABLE` statement supports `AVG_ROW_LENGTH` and `MAX_ROWS` options. See [Section 13.1.20, “CREATE TABLE Statement”](#). The server uses these options to determine how large a table to permit.

If the pointer size is too small for an existing table, you can change the options with `ALTER TABLE` to increase a table's maximum permissible size. See [Section 13.1.9, “ALTER TABLE Statement”](#).

```
ALTER TABLE tbl_name MAX_ROWS=1000000000 AVG_ROW_LENGTH=nnn;
```

You have to specify `AVG_ROW_LENGTH` only for tables with `BLOB` or `TEXT` columns; in this case, MySQL cannot optimize the space required based only on the number of rows.

To change the default size limit for `MyISAM` tables, set the `myisam_data_pointer_size`, which sets the number of bytes used for internal row pointers. The value is used to set the pointer size for new tables if you do not specify the `MAX_ROWS` option. The value of `myisam_data_pointer_size` can be from 2 to 7. A value of 4 permits tables up to 4GB; a value of 6 permits tables up to 256TB.

You can check the maximum data and index sizes by using this statement:

```
SHOW TABLE STATUS FROM db_name LIKE 'tbl_name' ;
```

You also can use `myisamchk -dv /path/to/table-index-file`. See [Section 13.7.7, “SHOW Statements”](#), or [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

Other ways to work around file-size limits for `MyISAM` tables are as follows:

- If your large table is read only, you can use `myisampack` to compress it. `myisampack` usually compresses a table by at least 50%, so you can have, in effect, much bigger tables. `myisampack` also can merge multiple tables into a single table. See [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).
- MySQL includes a `MERGE` library that enables you to handle a collection of `MyISAM` tables that have identical structure as a single `MERGE` table. See [Section 16.7, “The MERGE Storage Engine”](#).
- You are using the `MEMORY (HEAP)` storage engine; in this case you need to increase the value of the `max_heap_table_size` system variable. See [Section 5.1.8, “Server System Variables”](#).

8.4.7 Limits on Table Column Count and Row Size

This section describes limits on the number of columns in tables and the size of individual rows.

- [Column Count Limits](#)
- [Row Size Limits](#)

Column Count Limits

MySQL has hard limit of 4096 columns per table, but the effective maximum may be less for a given table. The exact column limit depends on several factors:

- The maximum row size for a table constrains the number (and possibly size) of columns because the total length of all columns cannot exceed this size. See [Row Size Limits](#).
- The storage requirements of individual columns constrain the number of columns that fit within a given maximum row size. Storage requirements for some data types depend on factors such as storage engine, storage format, and character set. See [Section 11.7, “Data Type Storage Requirements”](#).
- Storage engines may impose additional restrictions that limit table column count. For example, `InnoDB` has a limit of 1017 columns per table. See [Section 15.22, “InnoDB Limits”](#). For information about other storage engines, see [Chapter 16, Alternative Storage Engines](#).
- Functional key parts (see [Section 13.1.15, “CREATE INDEX Statement”](#)) are implemented as hidden virtual generated stored columns, so each functional key part in a table index counts against the table total column limit.

Row Size Limits

The maximum row size for a given table is determined by several factors:

- The internal representation of a MySQL table has a maximum row size limit of 65,535 bytes, even if the storage engine is capable of supporting larger rows. [BLOB](#) and [TEXT](#) columns only contribute 9 to 12 bytes toward the row size limit because their contents are stored separately from the rest of the row.
- The maximum row size for an [InnoDB](#) table, which applies to data stored locally within a database page, is slightly less than half a page for 4KB, 8KB, 16KB, and 32KB [innodb_page_size](#) settings. For example, the maximum row size is slightly less than 8KB for the default 16KB [InnoDB](#) page size. For 64KB pages, the maximum row size is slightly less than 16KB. See [Section 15.22, “InnoDB Limits”](#).

If a row containing [variable-length columns](#) exceeds the [InnoDB](#) maximum row size, [InnoDB](#) selects variable-length columns for external off-page storage until the row fits within the [InnoDB](#) row size limit. The amount of data stored locally for variable-length columns that are stored off-page differs by row format. For more information, see [Section 15.10, “InnoDB Row Formats”](#).

- Different storage formats use different amounts of page header and trailer data, which affects the amount of storage available for rows.
 - For information about [InnoDB](#) row formats, see [Section 15.10, “InnoDB Row Formats”](#).
 - For information about [MyISAM](#) storage formats, see [Section 16.2.3, “MyISAM Table Storage Formats”](#).

Row Size Limit Examples

- The MySQL maximum row size limit of 65,535 bytes is demonstrated in the following [InnoDB](#) and [MyISAM](#) examples. The limit is enforced regardless of storage engine, even though the storage engine may be capable of supporting larger rows.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
    c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
    f VARCHAR(10000), g VARCHAR(6000)) ENGINE=InnoDB CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. This includes storage overhead,
check the manual. You have to change some columns to TEXT or BLOBs
```

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
    c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
    f VARCHAR(10000), g VARCHAR(6000)) ENGINE=MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. This includes storage overhead,
check the manual. You have to change some columns to TEXT or BLOBs
```

In the following [MyISAM](#) example, changing a column to [TEXT](#) avoids the 65,535-byte row size limit and permits the operation to succeed because [BLOB](#) and [TEXT](#) columns only contribute 9 to 12 bytes toward the row size.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
    c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
    f VARCHAR(10000), g TEXT(6000)) ENGINE=MyISAM CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The operation succeeds for an [InnoDB](#) table because changing a column to [TEXT](#) avoids the MySQL 65,535-byte row size limit, and [InnoDB](#) off-page storage of variable-length columns avoids the [InnoDB](#) row size limit.

```
mysql> CREATE TABLE t (a VARCHAR(10000), b VARCHAR(10000),
    c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
    f VARCHAR(10000), g TEXT(6000)) ENGINE=InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

- Storage for variable-length columns includes length bytes, which are counted toward the row size. For example, a [VARCHAR\(255\) CHARACTER SET utf8mb3](#) column takes two bytes to store the length of the value, so each value can take up to 767 bytes.

The statement to create table `t1` succeeds because the columns require 32,765 + 2 bytes and 32,766 + 2 bytes, which falls within the maximum row size of 65,535 bytes:

```
mysql> CREATE TABLE t1
      (c1 VARCHAR(32765) NOT NULL, c2 VARCHAR(32766) NOT NULL)
      ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.02 sec)
```

The statement to create table `t2` fails because, although the column length is within the maximum length of 65,535 bytes, two additional bytes are required to record the length, which causes the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t2
      (c1 VARCHAR(65535) NOT NULL)
      ENGINE = InnoDB CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. This includes storage overhead,
check the manual. You have to change some columns to TEXT or BLOBs
```

Reducing the column length to 65,533 or less permits the statement to succeed.

```
mysql> CREATE TABLE t2
      (c1 VARCHAR(65533) NOT NULL)
      ENGINE = InnoDB CHARACTER SET latin1;
Query OK, 0 rows affected (0.01 sec)
```

- For [MyISAM](#) tables, [NULL](#) columns require additional space in the row to record whether their values are [NULL](#). Each [NULL](#) column takes one bit extra, rounded up to the nearest byte.

The statement to create table `t3` fails because [MyISAM](#) requires space for [NULL](#) columns in addition to the space required for variable-length column length bytes, causing the row size to exceed 65,535 bytes:

```
mysql> CREATE TABLE t3
      (c1 VARCHAR(32765) NULL, c2 VARCHAR(32766) NULL)
      ENGINE = MyISAM CHARACTER SET latin1;
ERROR 1118 (42000): Row size too large. The maximum row size for the used
table type, not counting BLOBs, is 65535. This includes storage overhead,
check the manual. You have to change some columns to TEXT or BLOBs
```

For information about [InnoDB NULL](#) column storage, see [Section 15.10, “InnoDB Row Formats”](#).

- [InnoDB](#) restricts row size (for data stored locally within the database page) to slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings, and to slightly less than 16KB for 64KB pages.

The statement to create table `t4` fails because the defined columns exceed the row size limit for a 16KB [InnoDB](#) page.

```
mysql> CREATE TABLE t4 (
      c1 CHAR(255),c2 CHAR(255),c3 CHAR(255),
      c4 CHAR(255),c5 CHAR(255),c6 CHAR(255),
      c7 CHAR(255),c8 CHAR(255),c9 CHAR(255),
      c10 CHAR(255),c11 CHAR(255),c12 CHAR(255),
      c13 CHAR(255),c14 CHAR(255),c15 CHAR(255),
      c16 CHAR(255),c17 CHAR(255),c18 CHAR(255),
      c19 CHAR(255),c20 CHAR(255),c21 CHAR(255),
      c22 CHAR(255),c23 CHAR(255),c24 CHAR(255),
      c25 CHAR(255),c26 CHAR(255),c27 CHAR(255),
      c28 CHAR(255),c29 CHAR(255),c30 CHAR(255),
      c31 CHAR(255),c32 CHAR(255),c33 CHAR(255)
      ) ENGINE=InnoDB ROW_FORMAT=DYNAMIC DEFAULT CHARSET latin1;
ERROR 1118 (42000): Row size too large (> 8126). Changing some columns to TEXT or BLOB may help.
In current row format, BLOB prefix of 0 bytes is stored inline.
```

8.5 Optimizing for InnoDB Tables

InnoDB is the storage engine that MySQL customers typically use in production databases where reliability and concurrency are important. **InnoDB** is the default storage engine in MySQL. This section explains how to optimize database operations for **InnoDB** tables.

8.5.1 Optimizing Storage Layout for InnoDB Tables

- Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the **OPTIMIZE TABLE** statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.

OPTIMIZE TABLE copies the data part of the table and rebuilds the indexes. The benefits come from improved packing of data within indexes, and reduced fragmentation within the tablespaces and on disk. The benefits vary depending on the data in each table. You may find that there are significant gains for some and not for others, or that the gains decrease over time until you next optimize the table. This operation can be slow if the table is large or if the indexes being rebuilt do not fit into the buffer pool. The first run after adding a lot of data to a table is often much slower than later runs.

- In **InnoDB**, having a long **PRIMARY KEY** (either a single column with a lengthy value, or several columns that form a long composite value) wastes a lot of disk space. The primary key value for a row is duplicated in all the secondary index records that point to the same row. (See [Section 15.6.2.1, “Clustered and Secondary Indexes”](#).) Create an **AUTO_INCREMENT** column as the primary key if your primary key is long, or index a prefix of a long **VARCHAR** column instead of the entire column.
- Use the **VARCHAR** data type instead of **CHAR** to store variable-length strings or for columns with many **NULL** values. A **CHAR(N)** column always takes *N* characters to store data, even if the string is shorter or its value is **NULL**. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using **COMPACT** row format (the default **InnoDB** format) and variable-length character sets, such as **utf8** or **sjis**, **CHAR(N)** columns occupy a variable amount of space, but still at least *N* bytes.

- For tables that are big, or contain lots of repetitive text or numeric data, consider using **COMPRESSED** row format. Less disk I/O is required to bring data into the buffer pool, or to perform full table scans. Before making a permanent decision, measure the amount of compression you can achieve by using **COMPRESSED** versus **COMPACT** row format.

8.5.2 Optimizing InnoDB Transaction Management

To optimize **InnoDB** transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting **AUTOCOMMIT=1** can impose performance limitations on a busy database server. Where practical, wrap several related data change operations into a single transaction, by issuing **SET AUTOCOMMIT=0** or a **START TRANSACTION** statement, followed by a **COMMIT** statement after making all the changes.

InnoDB must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Alternatively, for transactions that consist only of a single **SELECT** statement, turning on **AUTOCOMMIT** helps **InnoDB** to recognize read-only transactions and optimize them. See [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for requirements.

- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original data change operations. Killing the database process does not help, because the rollback starts again on server startup.

To minimize the chance of this issue occurring:

- Increase the size of the [buffer pool](#) so that all the data change changes can be cached rather than immediately written to disk.
- Set `innodb_change_buffering=all` so that update and delete operations are buffered in addition to inserts.
- Consider issuing `COMMIT` statements periodically during the big data change operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with `innodb_force_recovery=3`, as explained in [Section 15.18.2, “InnoDB Recovery”](#).

This issue is expected to be infrequent with the default setting `innodb_change_buffering=all`, which allows update and delete operations to be cached in memory, making them faster to perform in the first place, and also faster to roll back if needed. Make sure to use this parameter setting on servers that process long-running transactions with many inserts, updates, or deletes.

- If you can afford the loss of some of the latest committed transactions if an unexpected exit occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed.
- When rows are modified or deleted, the rows and associated [undo logs](#) are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent InnoDB from purging data that was changed by a different transaction.
- When rows are modified or deleted within a long-running transaction, other transactions using the `READ COMMITTED` and `REPEATABLE READ` isolation levels have to do more work to reconstruct the older data if they read those same rows.
- When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the [covering index](#) technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

If secondary index pages are found to have a `PAGE_MAX_TRX_ID` that is too new, or if records in the secondary index are delete-marked, InnoDB may need to look up records using a clustered index.

8.5.3 Optimizing InnoDB Read-Only Transactions

InnoDB can avoid the overhead associated with setting up the [transaction ID](#) (`TRX_ID` field) for transactions that are known to be read-only. A transaction ID is only needed for a [transaction](#) that might perform write operations or [locking reads](#) such as `SELECT ... FOR UPDATE`. Eliminating unnecessary transaction IDs reduces the size of internal data structures that are consulted each time a query or data change statement constructs a [read view](#).

InnoDB detects read-only transactions when:

- The transaction is started with the `START TRANSACTION READ ONLY` statement. In this case, attempting to make changes to the database (for InnoDB, MyISAM, or other types of tables) causes an error, and the transaction continues in read-only state:

```
ERROR 1792 (25006): Cannot execute statement in a READ ONLY transaction.
```

You can still make changes to session-specific temporary tables in a read-only transaction, or issue locking queries for them, because those changes and locks are not visible to any other transaction.

- The `autocommit` setting is turned on, so that the transaction is guaranteed to be a single statement, and the single statement making up the transaction is a “non-locking” `SELECT` statement. That is, a `SELECT` that does not use a `FOR UPDATE` or `LOCK IN SHARED MODE` clause.
- The transaction is started without the `READ ONLY` option, but no updates or statements that explicitly lock rows have been executed yet. Until updates or explicit locks are required, a transaction stays in read-only mode.

Thus, for a read-intensive application such as a report generator, you can tune a sequence of InnoDB queries by grouping them inside `START TRANSACTION READ ONLY` and `COMMIT`, or by turning on the `autocommit` setting before running the `SELECT` statements, or simply by avoiding any data change statements interspersed with the queries.

For information about `START TRANSACTION` and `autocommit`, see [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Statements”](#).

Note

Transactions that qualify as auto-commit, non-locking, and read-only (AC-NL-RO) are kept out of certain internal InnoDB data structures and are therefore not listed in `SHOW ENGINE INNODB STATUS` output.

8.5.4 Optimizing InnoDB Redo Logging

Consider the following guidelines for optimizing redo logging:

- Make your redo log files big, even as big as the `buffer pool`. When InnoDB has written the redo log files full, it must write the modified contents of the buffer pool to disk in a `checkpoint`. Small redo log files cause many unnecessary disk writes. Although historically big redo log files caused lengthy recovery times, recovery is now much faster and you can confidently use large redo log files.

The size and number of redo log files are configured using the `innodb_log_file_size` and `innodb_log_files_in_group` configuration options. For information about modifying an existing redo log file configuration, see [Changing the Number or Size of Redo Log Files](#).

- Consider increasing the size of the `log buffer`. A large log buffer enables large `transactions` to run without a need to write the log to disk before the transactions `commit`. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. Log buffer size is configured using the `innodb_log_buffer_size` configuration option, which can be configured dynamically in MySQL 8.0.
- Configure the `innodb_log_write_ahead_size` configuration option to avoid “read-on-write”. This option defines the write-ahead block size for the redo log. Set `innodb_log_write_ahead_size` to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for the redo log and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size (2^n). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to the `innodb_page_size` value. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` setting is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in read-on-write. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

- MySQL 8.0.11 introduced dedicated log writer threads for writing redo log records from the log buffer to the system buffers and flushing the system buffers to the redo log files. Previously, individual user threads were responsible those tasks. As of MySQL 8.0.22, you can enable or disable log writer threads using the `innodb_log_writer_threads` variable. Dedicated log writer threads can improve performance on high-concurrency systems, but for low-concurrency systems, disabling dedicated log writer threads provides better performance.
- Optimize the use of spin delay by user threads waiting for flushed redo. Spin delay helps reduce latency. During periods of low concurrency, reducing latency may be less of a priority, and avoiding the use of spin delay during these periods may reduce energy consumption. During periods of high concurrency, you may want to avoid expending processing power on spin delay so that it can be used for other work. The following system variables permit setting high and low watermark values that define boundaries for the use of spin delay.
 - `innodb_log_wait_for_flush_spin_hwm`: Defines the maximum average log flush time beyond which user threads no longer spin while waiting for flushed redo. The default value is 400 microseconds.
 - `innodb_log_spin_cpu_abs_lwm`: Defines the minimum amount of CPU usage below which user threads no longer spin while waiting for flushed redo. The value is expressed as a sum of CPU core usage. For example, The default value of 80 is 80% of a single CPU core. On a system with a multi-core processor, a value of 150 represents 100% usage of one CPU core plus 50% usage of a second CPU core.
 - `innodb_log_spin_cpu_pct_hwm`: Defines the maximum amount of CPU usage above which user threads no longer spin while waiting for flushed redo. The value is expressed as a percentage of the combined total processing power of all CPU cores. The default value is 50%. For example, 100% usage of two CPU cores is 50% of the combined CPU processing power on a server with four CPU cores.

The `innodb_log_spin_cpu_pct_hwm` configuration option respects processor affinity. For example, if a server has 48 cores but the `mysqld` process is pinned to only four CPU cores, the other 44 CPU cores are ignored.

8.5.5 Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in [Section 8.2.5.1](#), “Optimizing INSERT Statements”.

- When importing data into **InnoDB**, turn off autocommit mode, because it performs a log flush to disk for every insert. To disable autocommit during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

```
SET autocommit=0;
... SQL import statements ...
COMMIT;
```

The `mysqldump` option `--opt` creates dump files that are fast to import into an **InnoDB** table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- If you have **UNIQUE** constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET unique_checks=0;
... SQL import statements ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because [InnoDB](#) can use its change buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have [FOREIGN KEY](#) constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

```
SET foreign_key_checks=0;
... SQL import statements ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

- Use the multiple-row [INSERT](#) syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just [InnoDB](#) tables.

- When doing bulk inserts into tables with auto-increment columns, set [innodb_autoinc_lock_mode](#) to 2 (interleaved) instead of 1 (consecutive). See [Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”](#) for details.
- When performing bulk inserts, it is faster to insert rows in [PRIMARY KEY](#) order. [InnoDB](#) tables use a [clustered index](#), which makes it relatively fast to use data in the order of the [PRIMARY KEY](#). Performing bulk inserts in [PRIMARY KEY](#) order is particularly important for tables that do not fit entirely within the buffer pool.
- For optimal performance when loading data into an [InnoDB FULLTEXT](#) index, follow this set of steps:
 1. Define a column [FTS_DOC_ID](#) at table creation time, of type [BIGINT UNSIGNED NOT NULL](#), with a unique index named [FTS_DOC_ID_INDEX](#). For example:

```
CREATE TABLE t1 (
  FTS_DOC_ID BIGINT unsigned NOT NULL AUTO_INCREMENT,
  title varchar(255) NOT NULL DEFAULT '',
  text mediumtext NOT NULL,
  PRIMARY KEY (`FTS_DOC_ID`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on t1(FTS_DOC_ID);
```

2. Load the data into the table.
3. Create the [FULLTEXT](#) index after the data is loaded.

Note

When adding [FTS_DOC_ID](#) column at table creation time, ensure that the [FTS_DOC_ID](#) column is updated when the [FULLTEXT](#) indexed column is updated, as the [FTS_DOC_ID](#) must increase monotonically with each [INSERT](#) or [UPDATE](#). If you choose not to add the [FTS_DOC_ID](#) at table creation time and have [InnoDB](#) manage DOC IDs for you, [InnoDB](#) will add the [FTS_DOC_ID](#) as a hidden column with the next [CREATE FULLTEXT INDEX](#) call. This approach, however, requires a table rebuild which will impact performance.

8.5.6 Optimizing InnoDB Queries

To tune queries for [InnoDB](#) tables, create an appropriate set of indexes on each table. See [Section 8.3.1, “How MySQL Uses Indexes”](#) for details. Follow these guidelines for [InnoDB](#) indexes:

- Because each [InnoDB](#) table has a [primary key](#) (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.
- Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.
- Do not create a separate [secondary index](#) for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of [concatenated indexes](#) rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a [covering index](#)), the query might be able to avoid reading the table data at all.
- If an indexed column cannot contain any [NULL](#) values, declare it as [NOT NULL](#) when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains [NULL](#) values.
- You can optimize single-query transactions for [InnoDB](#) tables, using the technique in [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#).

8.5.7 Optimizing InnoDB DDL Operations

- Many DDL operations on tables and indexes ([CREATE](#), [ALTER](#), and [DROP](#) statements) can be performed online. See [Section 15.12, “InnoDB and Online DDL”](#) for details.
- Online DDL support for adding secondary indexes means that you can generally speed up the process of creating and loading a table and associated indexes by creating the table without secondary indexes, then adding secondary indexes after the data is loaded.
- Use [TRUNCATE TABLE](#) to empty a table, not [DELETE FROM tbl_name](#). Foreign key constraints can make a [TRUNCATE](#) statement work like a regular [DELETE](#) statement, in which case a sequence of commands like [DROP TABLE](#) and [CREATE TABLE](#) might be fastest.
- Because the primary key is integral to the storage layout of each [InnoDB](#) table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the [CREATE TABLE](#) statement, and plan ahead so that you do not need to [ALTER](#) or [DROP](#) the primary key afterward.

8.5.8 Optimizing InnoDB Disk I/O

If you follow best practices for database design and tuning techniques for SQL operations, but your database is still slow due to heavy disk I/O activity, consider these disk I/O optimizations. If the Unix [top](#) tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

- Increase buffer pool size

When table data is cached in the [InnoDB](#) buffer pool, it can be accessed repeatedly by queries without requiring any disk I/O. Specify the size of the buffer pool with the [innodb_buffer_pool_size](#) option. This memory area is important enough that it is typically recommended that [innodb_buffer_pool_size](#) is configured to 50 to 75 percent of system memory. For more information see, [Section 8.12.3.1, “How MySQL Uses Memory”](#).

- Adjust the flush method

In some versions of GNU/Linux and Unix, flushing files to disk with the Unix [fsync\(\)](#) call (which [InnoDB](#) uses by default) and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the [innodb_flush_method](#) parameter set to [O_DSYNC](#).

- Configure an fsync threshold

By default, when [InnoDB](#) creates a new data file, such as a new log file or tablespace file, the file is fully written to the operating system cache before it is flushed to disk, which can cause a large amount of disk write activity to occur at once. To force smaller, periodic flushes of data from the operating system cache, you can use the [innodb_fsync_threshold](#) variable to define a threshold value, in bytes. When the byte threshold is reached, the contents of the operating system cache are flushed to disk. The default value of 0 forces the default behavior, which is to flush data to disk only after a file is fully written to the cache.

Specifying a threshold to force smaller, periodic flushes may be beneficial in cases where multiple MySQL instances use the same storage devices. For example, creating a new MySQL instance and its associated data files could cause large surges of disk write activity, impeding the performance of other MySQL instances that use the same storage devices. Configuring a threshold helps avoid such surges in write activity.

- Use a noop or deadline I/O scheduler with native AIO on Linux

[InnoDB](#) uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the [innodb_use_native_aio](#) configuration option, which is enabled by default. With native AIO, the type of I/O scheduler has greater influence on I/O performance. Generally, noop and deadline I/O schedulers are recommended. Conduct benchmarks to determine which I/O scheduler provides the best results for your workload and environment. For more information, see [Section 15.8.6, “Using Asynchronous I/O on Linux”](#).

- Use direct I/O on Solaris 10 for x86_64 architecture

When using the [InnoDB](#) storage engine on Solaris 10 for x86_64 architecture (AMD Opteron), use direct I/O for [InnoDB](#)-related files to avoid degradation of [InnoDB](#) performance. To use direct I/O for an entire UFS file system used for storing [InnoDB](#)-related files, mount it with the [forcedirectio](#) option; see [mount_ufs\(1M\)](#). (The default on Solaris 10/x86_64 is *not* to use this option.) To apply direct I/O only to [InnoDB](#) file operations rather than the whole file system, set [innodb_flush_method = O_DIRECT](#). With this setting, [InnoDB](#) calls [directio\(\)](#) instead of [fcntl\(\)](#) for I/O to data files (not for I/O to log files).

- Use raw storage for data and log files with Solaris 2.6 or later

When using the [InnoDB](#) storage engine with a large [innodb_buffer_pool_size](#) value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with [InnoDB](#) data files and log files on raw devices or on a separate direct I/O UFS file system, using the [forcedirectio](#) mount option as described previously. (It is necessary to use the mount option rather than setting [innodb_flush_method](#) if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the [convosync=direct](#) mount option.

Do not place other MySQL data files, such as those for [MyISAM](#) tables, on a direct I/O file system. Executables or libraries *must not* be placed on a direct I/O file system.

- Use additional storage devices

Additional storage devices could be used to set up a RAID configuration. For related information, see [Section 8.12.1, “Optimizing Disk I/O”](#).

Alternatively, [InnoDB](#) tablespace data files and log files can be placed on different physical disks. For more information, refer to the following sections:

- [Section 15.8.1, “InnoDB Startup Configuration”](#)
- [Section 15.6.1.2, “Creating Tables Externally”](#)
- [Creating a General Tablespace](#)

- [Section 15.6.1.4, “Moving or Copying InnoDB Tables”](#)
- Consider non-rotational storage

Non-rotational storage generally provides better performance for random I/O operations; and rotational storage for sequential I/O operations. When distributing data and log files across rotational and non-rotational storage devices, consider the type of I/O operations that are predominantly performed on each file.

Random I/O-oriented files typically include [file-per-table](#) and [general tablespace](#) data files, [undo tablespace](#) files, and [temporary tablespace](#) files. Sequential I/O-oriented files include [InnoDB system tablespace](#) files (due to [doublewrite buffering](#) prior to MySQL 8.0.20 and [change buffering](#)), doublewrite files introduced in MySQL 8.0.20, and log files such as [binary log](#) files and [redo log](#) files.

Review settings for the following configuration options when using non-rotational storage:

- [innodb_checksum_algorithm](#)

The [crc32](#) option uses a faster checksum algorithm and is recommended for fast storage systems.

- [innodb_flush_neighbors](#)

Optimizes I/O for rotational storage devices. Disable it for non-rotational storage or a mix of rotational and non-rotational storage. It is disabled by default.

- [innodb_idle_flush_pct](#)

Permits placing a limit on page flushing during idle periods, which can help extend the life of non-rotational storage devices. Introduced in MySQL 8.0.18.

- [innodb_io_capacity](#)

The default setting of 200 is generally sufficient for a lower-end non-rotational storage device. For higher-end, bus-attached devices, consider a higher setting such as 1000.

- [innodb_io_capacity_max](#)

The default value of 2000 is intended for workloads that use non-rotational storage. For a high-end, bus-attached non-rotational storage device, consider a higher setting such as 2500.

- [innodb_log_compressed_pages](#)

If redo logs are on non-rotational storage, consider disabling this option to reduce logging. See [Disable logging of compressed pages](#).

- [innodb_log_file_size](#)

If redo logs are on non-rotational storage, configure this option to maximize caching and write combining.

- [innodb_page_size](#)

Consider using a page size that matches the internal sector size of the disk. Early-generation SSD devices often have a 4KB sector size. Some newer devices have a 16KB sector size. The

default InnoDB page size is 16KB. Keeping the page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

- `binlog_row_image`

If binary logs are on non-rotational storage and all tables have primary keys, consider setting this option to `minimal` to reduce logging.

Ensure that TRIM support is enabled for your operating system. It is typically enabled by default.

- Increase I/O capacity to avoid backlogs

If throughput drops periodically because of InnoDB `checkpoint` operations, consider increasing the value of the `innodb_io_capacity` configuration option. Higher values cause more frequent `flushing`, avoiding the backlog of work that can cause dips in throughput.

- Lower I/O capacity if flushing does not fall behind

If the system is not falling behind with InnoDB `flushing` operations, consider lowering the value of the `innodb_io_capacity` configuration option. Typically, you keep this option value as low as practical, but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from `SHOW ENGINE INNODB STATUS`:

- History list length low, below a few thousand.
- Insert buffer merges close to rows inserted.
- Modified pages in buffer pool consistently well below `innodb_max_dirty_pages_pct` of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)
- `Log sequence number - Last checkpoint` is at less than 7/8 or ideally less than 6/8 of the total size of the InnoDB log files.
- Store system tablespace files on Fusion-io devices

You can take advantage of a doublewrite buffer-related I/O optimization by storing the files that contain the doublewrite storage area on Fusion-io devices that support atomic writes. (Prior to MySQL 8.0.20, the doublewrite buffer storage area resides in the system tablespace data files. As of MySQL 8.0.20, the storage area resides in doublewrite files. See [Section 15.6.4, “Doublewrite Buffer”](#).) When doublewrite storage area files are placed on Fusion-io devices that support atomic writes, the doublewrite buffer is automatically disabled and Fusion-io atomic writes are used for all data files. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMeFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

Note

Because the doublewrite buffer setting is global, the doublewrite buffer is also disabled for data files that do not reside on Fusion-io hardware.

- Disable logging of compressed pages

When using the InnoDB table `compression` feature, images of re-compressed `pages` are written to the `redo log` when changes are made to compressed data. This behavior is controlled by `innodb_log_compressed_pages`, which is enabled by default to prevent corruption that can occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version will not change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

8.5.9 Optimizing InnoDB Configuration Variables

Different settings work best for servers with light, predictable loads, versus servers that are running near full capacity all the time, or that experience spikes of high activity.

Because the [InnoDB](#) storage engine performs many of its optimizations automatically, many performance-tuning tasks involve monitoring to ensure that the database is performing well, and changing configuration options when performance drops. See [Section 15.16, “InnoDB Integration with MySQL Performance Schema”](#) for information about detailed [InnoDB](#) performance monitoring.

The main configuration steps you can perform include:

- Controlling the types of data change operations for which [InnoDB](#) buffers the changed data, to avoid frequent small disk writes. See [Configuring Change Buffering](#). Because the default is to buffer all types of data change operations, only change this setting if you need to reduce the amount of buffering.
- Turning the adaptive hash indexing feature on and off using the `innodb_adaptive_hash_index` option. See [Section 15.5.3, “Adaptive Hash Index”](#) for more information. You might change this setting during periods of unusual activity, then restore it to its original setting.
- Setting a limit on the number of concurrent threads that [InnoDB](#) processes, if context switching is a bottleneck. See [Section 15.8.4, “Configuring Thread Concurrency for InnoDB”](#).
- Controlling the amount of prefetching that [InnoDB](#) does with its read-ahead operations. When the system has unused I/O capacity, more read-ahead can improve the performance of queries. Too much read-ahead can cause periodic drops in performance on a heavily loaded system. See [Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).
- Increasing the number of background threads for read or write operations, if you have a high-end I/O subsystem that is not fully utilized by the default values. See [Section 15.8.5, “Configuring the Number of Background InnoDB I/O Threads”](#).
- Controlling how much I/O [InnoDB](#) performs in the background. See [Section 15.8.7, “Configuring InnoDB I/O Capacity”](#). You might scale back this setting if you observe periodic drops in performance.
- Controlling the algorithm that determines when [InnoDB](#) performs certain types of background writes. See [Section 15.8.3.5, “Configuring Buffer Pool Flushing”](#). The algorithm works for some types of workloads but not others, so you might disable this feature if you observe periodic drops in performance.
- Taking advantage of multicore processors and their cache memory configuration, to minimize delays in context switching. See [Section 15.8.8, “Configuring Spin Lock Polling”](#).
- Preventing one-time operations such as table scans from interfering with the frequently accessed data stored in the [InnoDB](#) buffer cache. See [Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”](#).
- Adjusting log files to a size that makes sense for reliability and crash recovery. [InnoDB](#) log files have often been kept small to avoid long startup times after a crash. Optimizations introduced in MySQL 5.5 speed up certain steps of the crash [recovery](#) process. In particular, scanning the [redo log](#) and applying the redo log are faster due to improved algorithms for memory management. If you have kept your log files artificially small to avoid long startup times, you can now consider increasing log file size to reduce the I/O that occurs due recycling of redo log records.
- Configuring the size and number of instances for the [InnoDB](#) buffer pool, especially important for systems with multi-gigabyte buffer pools. See [Section 15.8.3.2, “Configuring Multiple Buffer Pool Instances”](#).
- Increasing the maximum number of concurrent transactions, which dramatically improves scalability for the busiest databases. See [Section 15.6.6, “Undo Logs”](#).

- Moving purge operations (a type of garbage collection) into a background thread. See [Section 15.8.9, “Purge Configuration”](#). To effectively measure the results of this setting, tune the other I/O-related and thread-related configuration settings first.
- Reducing the amount of switching that InnoDB does between concurrent threads, so that SQL operations on a busy server do not queue up and form a “traffic jam”. Set a value for the `innodb_thread_concurrency` option, up to approximately 32 for a high-powered modern system. Increase the value for the `innodb_concurrency_tickets` option, typically to 5000 or so. This combination of options sets a cap on the number of threads that InnoDB processes at any one time, and allows each thread to do substantial work before being swapped out, so that the number of waiting threads stays low and operations can complete without excessive context switching.

8.5.10 Optimizing InnoDB for Systems with Many Tables

- If you have configured [non-persistent optimizer statistics](#) (a non-default configuration), InnoDB computes index [cardinality](#) values for a table the first time that table is accessed after startup, instead of storing such values in the table. This step can take significant time on systems that partition the data into many tables. Since this overhead only applies to the initial table open operation, to “warm up” a table for later use, access it immediately after startup by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

Optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see [Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

8.6 Optimizing for MyISAM Tables

The [MyISAM](#) storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates. In MySQL, InnoDB is the default storage engine rather than [MyISAM](#).

8.6.1 Optimizing MyISAM Queries

Some general tips for speeding up queries on [MyISAM](#) tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.
- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.
- Try to avoid complex `SELECT` queries on [MyISAM](#) tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.
- [MyISAM](#) supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See [Section 8.11.3, “Concurrent Inserts”](#).

- For **MyISAM** tables that change frequently, try to avoid all variable-length columns (**VARCHAR**, **BLOB**, and **TEXT**). The table uses dynamic row format if it includes even a single variable-length column. See [Chapter 16, Alternative Storage Engines](#).
- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a **MyISAM** table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See [Chapter 16, Alternative Storage Engines](#).
- Use **ALTER TABLE ... ORDER BY *expr1*, *expr2*, ...** if you usually retrieve rows in *expr1*, *expr2*, ... order. By using this option after extensive changes to the table, you may be able to get higher performance.
- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use MySQL storage engines such as **MyISAM** that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use **OPTIMIZE TABLE** periodically to avoid fragmentation with dynamic-format **MyISAM** tables. See [Section 16.2.3, “MyISAM Table Storage Formats”](#).
- Declaring a **MyISAM** table with the **DELAY_KEY_WRITE=1** table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the **myisam_recover_options** system variable set, or by running **myisamchk** before restarting the server. (However, even in this case, you should not lose anything by using **DELAY_KEY_WRITE**, because the key information can always be generated from the data rows.)
- Strings are automatically prefix- and end-space compressed in **MyISAM** indexes. See [Section 13.1.15, “CREATE INDEX Statement”](#).
- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates.

8.6.2 Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in [Section 8.2.5.1, “Optimizing INSERT Statements”](#).

- For a **MyISAM** table, you can use concurrent inserts to add rows at the same time that **SELECT** statements are running, if there are no deleted rows in middle of the data file. See [Section 8.11.3, “Concurrent Inserts”](#).
- With some extra work, it is possible to make **LOAD DATA** run even faster for a **MyISAM** table when the table has many indexes. Use the following procedure:
 1. Execute a **FLUSH TABLES** statement or a **mysqladmin flush-tables** command.
 2. Use **myisamchk --keys-used=0 -rq /path/to/db/tbl_name** to remove all use of indexes for the table.
 3. Insert data into the table with **LOAD DATA**. This does not update any indexes and therefore is very fast.

4. If you intend only to read from the table in the future, use `myisampack` to compress it. See [Section 16.2.3.3, “Compressed Table Characteristics”](#).
5. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during `LOAD DATA` because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
6. Execute a `FLUSH TABLES` statement or a `mysqladmin flush-tables` command.

`LOAD DATA` performs the preceding optimization automatically if the `MyISAM` table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the `LOAD DATA` statement.

You can also disable or enable the nonunique indexes for a `MyISAM` table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the `FLUSH TABLES` operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up `INSERT` operations that are performed with multiple statements for nontransactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all `INSERT` statements have completed. Normally, there would be as many index buffer flushes as there are `INSERT` statements. Explicit locking statements are not needed if you can insert all rows with a single `INSERT`.

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert
- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA`, even when using the strategies just outlined.

- To increase performance for [MyISAM](#) tables, for both [LOAD DATA](#) and [INSERT](#), enlarge the key cache by increasing the [key_buffer_size](#) system variable. See [Section 5.1.1](#), “Configuring the Server”.

8.6.3 Optimizing REPAIR TABLE Statements

[REPAIR TABLE](#) for [MyISAM](#) tables is similar to using [myisamchk](#) for repair operations, and some of the same performance optimizations apply:

- [myisamchk](#) has variables that control memory allocation. You may be able to improve performance by setting these variables, as described in [Section 4.6.4.6](#), “[myisamchk](#) Memory Usage”.
- For [REPAIR TABLE](#), the same principle applies, but because the repair is done by the server, you set server system variables instead of [myisamchk](#) variables. Also, in addition to setting memory-allocation variables, increasing the [myisam_max_sort_file_size](#) system variable increases the likelihood that the repair will use the faster filesort method and avoid the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a [myisamchk](#) table-repair operation is done using the following options to set its memory-allocation variables:

```
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those [myisamchk](#) variables correspond to server system variables:

myisamchk Variable	System Variable
key_buffer_size	key_buffer_size
myisam_sort_buffer_size	myisam_sort_buffer_size
read_buffer_size	read_buffer_size
write_buffer_size	none

Each of the server system variables can be set at runtime, and some of them ([myisam_sort_buffer_size](#), [read_buffer_size](#)) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable ([key_buffer_size](#), [myisam_max_sort_file_size](#)) affects other users as well. For [key_buffer_size](#), you must take into account that the buffer is shared with those users. For example, if you set the [myisamchk](#) [key_buffer_size](#) variable to 128MB, you could set the corresponding [key_buffer_size](#) system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See [Section 8.10.2.2](#), “Multiple Key Caches”.

Based on the preceding remarks, a [REPAIR TABLE](#) operation can be done as follows to use settings similar to the [myisamchk](#) command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
REPAIR TABLE tbl_name ;
```

```
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a [REPAIR TABLE](#) operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```
SET @old_myisam_sort_buffer_size = @@GLOBAL.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE tbl_name ;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```

The system variables that affect [REPAIR TABLE](#) can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server `my.cnf` file:

```
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include [read_buffer_size](#). Setting [read_buffer_size](#) globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.

8.7 Optimizing for MEMORY Tables

Consider using [MEMORY](#) tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent [InnoDB](#) or [MyISAM](#) tables under a realistic workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with [MEMORY](#) tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the [CREATE INDEX](#) statement, use the clause [USING BTREE](#) or [USING HASH](#). B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as [>](#) or [BETWEEN](#). Hash indexes are only fast for queries that look up single values through the [=](#) operator, or a restricted set of values through the [IN](#) operator. For why [USING BTREE](#) is often a better choice than the default [USING HASH](#), see [Section 8.2.1.23, “Avoiding Full Table Scans”](#). For implementation details of the different types of [MEMORY](#) indexes, see [Section 8.3.9, “Comparison of B-Tree and Hash Indexes”](#).

8.8 Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your [WHERE](#) clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform the most efficient query is called the “query execution plan”, also known as the [EXPLAIN](#) plan. Your goals are to recognize the aspects of the [EXPLAIN](#) plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

8.8.1 Optimizing Queries with EXPLAIN

The [EXPLAIN](#) statement provides information about how MySQL executes statements:

- [EXPLAIN](#) works with [SELECT](#), [DELETE](#), [INSERT](#), [REPLACE](#), and [UPDATE](#) statements.
- When [EXPLAIN](#) is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using [EXPLAIN](#) to obtain execution plan information, see [Section 8.8.2, “EXPLAIN Output Format”](#).

- When `EXPLAIN` is used with `FOR CONNECTION connection_id` rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See [Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).
- For `SELECT` statements, `EXPLAIN` produces additional execution plan information that can be displayed using `SHOW WARNINGS`. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).
- `EXPLAIN` is useful for examining queries involving partitioned tables. See [Section 23.3.5, “Obtaining Information About Partitions”](#).
- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 13.2.10, “SELECT Statement”](#).) However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#).

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see [MySQL Internals: Tracing the Optimizer](#).

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 13.7.3.1, “ANALYZE TABLE Statement”](#).

Note

`EXPLAIN` can also be used to obtain information about the columns in a table. `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` and `SHOW COLUMNS FROM tbl_name`. For more information, see [Section 13.8.1, “DESCRIBE Statement”](#), and [Section 13.7.7.5, “SHOW COLUMNS Statement”](#).

8.8.2 EXPLAIN Output Format

The `EXPLAIN` statement provides information about how MySQL executes statements. `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. This means that MySQL reads a row from the first table, then finds a matching row in the second table, and then in the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

Note

MySQL Workbench has a Visual Explain capability that provides a visual representation of `EXPLAIN` output. See [Tutorial: Using Explain to Improve Query Performance](#).

- [EXPLAIN Output Columns](#)
- [EXPLAIN Join Types](#)
- [EXPLAIN Extra Information](#)

- [EXPLAIN Output Interpretation](#)

EXPLAIN Output Columns

This section describes the output columns produced by [EXPLAIN](#). Later sections provide additional information about the [type](#) and [Extra](#) columns.

Each output row from [EXPLAIN](#) provides information about one table. Each row contains the values summarized in [Table 8.1, “EXPLAIN Output Columns”](#), and described in more detail following the table. Column names are shown in the table's first column; the second column provides the equivalent property name shown in the output when [FORMAT=JSON](#) is used.

Table 8.1 EXPLAIN Output Columns

Column	JSON Name	Meaning
id	select_id	The SELECT identifier
select_type	None	The SELECT type
table	table_name	The table for the output row
partitions	partitions	The matching partitions
type	access_type	The join type
possible_keys	possible_keys	The possible indexes to choose
key	key	The index actually chosen
key_len	key_length	The length of the chosen key
ref	ref	The columns compared to the index
rows	rows	Estimate of rows to be examined
filtered	filtered	Percentage of rows filtered by table condition
Extra	None	Additional information

Note

JSON properties which are [NULL](#) are not displayed in JSON-formatted [EXPLAIN](#) output.

- [id](#) (JSON name: [select_id](#))

The [SELECT](#) identifier. This is the sequential number of the [SELECT](#) within the query. The value can be [NULL](#) if the row refers to the union result of other rows. In this case, the [table](#) column shows a value like [<unionM,N>](#) to indicate that the row refers to the union of the rows with [id](#) values of [M](#) and [N](#).

- [select_type](#) (JSON name: none)

The type of [SELECT](#), which can be any of those shown in the following table. A JSON-formatted [EXPLAIN](#) exposes the [SELECT](#) type as a property of a [query_block](#), unless it is [SIMPLE](#) or [PRIMARY](#). The JSON names (where applicable) are also shown in the table.

select_type Value	JSON Name	Meaning
SIMPLE	None	Simple SELECT (not using UNION or subqueries)
PRIMARY	None	Outermost SELECT
UNION	None	Second or later SELECT statement in a UNION
DEPENDENT UNION	dependent (true)	Second or later SELECT statement in a UNION , dependent on outer query
UNION RESULT	union_result	Result of a UNION .

<code>select_type</code> Value	JSON Name	Meaning
SUBQUERY	None	First <code>SELECT</code> in subquery
DEPENDENT SUBQUERY	<code>dependent</code> (<code>true</code>)	First <code>SELECT</code> in subquery, dependent on outer query
DERIVED	None	Derived table
DEPENDENT DERIVED	<code>dependent</code> (<code>true</code>)	Derived table dependent on another table
MATERIALIZED	<code>materialized_from_subquery</code>	Materialized subquery
UNCACHEABLE SUBQUERY	<code>cacheable</code> (<code>false</code>)	A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query
UNCACHEABLE UNION	<code>cacheable</code> (<code>false</code>)	The second or later select in a <code>UNION</code> that belongs to an uncacheable subquery (see <code>UNCACHEABLE SUBQUERY</code>)

`DEPENDENT` typically signifies the use of a correlated subquery. See [Section 13.2.11.7, “Correlated Subqueries”](#).

`DEPENDENT SUBQUERY` evaluation differs from `UNCACHEABLE SUBQUERY` evaluation. For `DEPENDENT SUBQUERY`, the subquery is re-evaluated only once for each set of different values of the variables from its outer context. For `UNCACHEABLE SUBQUERY`, the subquery is re-evaluated for each row of the outer context.

When you specify `FORMAT=JSON` with `EXPLAIN`, the output has no single property directly equivalent to `select_type`; the `query_block` property corresponds to a given `SELECT`. Properties equivalent to most of the `SELECT` subquery types just shown are available (an example being `materialized_from_subquery` for `MATERIALIZED`), and are displayed when appropriate. There are no JSON equivalents for `SIMPLE` or `PRIMARY`.

The `select_type` value for non-`SELECT` statements displays the statement type for affected tables. For example, `select_type` is `DELETE` for `DELETE` statements.

- `table` (JSON name: `table_name`)

The name of the table to which the row of output refers. This can also be one of the following values:

- `<unionM,N>`: The row refers to the union of the rows with `id` values of `M` and `N`.
- `<derivedN>`: The row refers to the derived table result for the row with an `id` value of `N`. A derived table may result, for example, from a subquery in the `FROM` clause.
- `<subqueryN>`: The row refers to the result of a materialized subquery for the row with an `id` value of `N`. See [Section 8.2.2.2, “Optimizing Subqueries with Materialization”](#).

- `partitions` (JSON name: `partitions`)

The partitions from which records would be matched by the query. The value is `NULL` for nonpartitioned tables. See [Section 23.3.5, “Obtaining Information About Partitions”](#).

- `type` (JSON name: `access_type`)

The join type. For descriptions of the different types, see [EXPLAIN Join Types](#).

- `possible_keys` (JSON name: `possible_keys`)

The `possible_keys` column indicates the indexes from which MySQL can choose to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

If this column is `NULL` (or undefined in JSON-formatted output), there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See [Section 13.1.9, “ALTER TABLE Statement”](#).

To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key` (JSON name: `key`)

The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

It is possible that `key` will name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

For `InnoDB`, a secondary index might cover the selected columns even if the query also selects the primary key because `InnoDB` stores the primary key value with each secondary index. If `key` is `NULL`, MySQL found no index to use for executing the query more efficiently.

To force MySQL to use or ignore an index listed in the `possible_keys` column, use `FORCE INDEX`, `USE INDEX`, or `IGNORE INDEX` in your query. See [Section 8.9.4, “Index Hints”](#).

For `MyISAM` tables, running `ANALYZE TABLE` helps the optimizer choose better indexes. For `MyISAM` tables, `myisamchk --analyze` does the same. See [Section 13.7.3.1, “ANALYZE TABLE Statement”](#), and [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

- `key_len` (JSON name: `key_length`)

The `key_len` column indicates the length of the key that MySQL decided to use. The value of `key_len` enables you to determine how many parts of a multiple-part key MySQL actually uses. If the `key` column says `NULL`, the `key_len` column also says `NULL`.

Due to the key storage format, the key length is one greater for a column that can be `NULL` than for a `NOT NULL` column.

- `ref` (JSON name: `ref`)

The `ref` column shows which columns or constants are compared to the index named in the `key` column to select rows from the table.

If the value is `func`, the value used is the result of some function. To see which function, use `SHOW WARNINGS` following `EXPLAIN` to see the extended `EXPLAIN` output. The function might actually be an operator such as an arithmetic operator.

- `rows` (JSON name: `rows`)

The `rows` column indicates the number of rows MySQL believes it must examine to execute the query.

For `InnoDB` tables, this number is an estimate, and may not always be exact.

- `filtered` (JSON name: `filtered`)

The `filtered` column indicates an estimated percentage of table rows that will be filtered by the table condition. The maximum value is 100, which means no filtering of rows occurred. Values decreasing from 100 indicate increasing amounts of filtering. `rows` shows the estimated number of rows examined and `rows × filtered` shows the number of rows that will be joined with the

following table. For example, if `rows` is 1000 and `filtered` is 50.00 (50%), the number of rows to be joined with the following table is $1000 \times 50\% = 500$.

- `Extra` (JSON name: none)

This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see [EXPLAIN Extra Information](#).

There is no single JSON property corresponding to the `Extra` column; however, values that can occur in this column are exposed as JSON properties, or as the text of the `message` property.

EXPLAIN Join Types

The `type` column of `EXPLAIN` output describes how tables are joined. In JSON-formatted output, these are found as values of the `access_type` property. The following list describes the join types, ordered from the best type to the worst:

- `system`

The table has only one row (= system table). This is a special case of the `const` join type.

- `const`

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` tables are very fast because they are read only once.

`const` is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, `tbl_name` can be used as a `const` table:

```
SELECT * FROM tbl_name WHERE primary_key=1;

SELECT * FROM tbl_name
WHERE primary_key_part1=1 AND primary_key_part2=2;
```

- `eq_ref`

One row is read from this table for each combination of rows from the previous tables. Other than the `system` and `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE NOT NULL` index.

`eq_ref` can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` join to process `ref_table`:

```
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `ref`

All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` join to process `ref_table`:

```
SELECT * FROM ref_table WHERE key_column=expr;
```

```
SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
  WHERE ref_table.key_column_part1=other_table.column
  AND ref_table.key_column_part2=1;
```

- `fulltext`

The join is performed using a `FULLTEXT` index.

- `ref_or_null`

This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a `ref_or_null` join to process *ref_table*:

```
SELECT * FROM ref_table
  WHERE key_column=expr OR key_column IS NULL;
```

See [Section 8.2.1.15, “IS NULL Optimization”](#).

- `index_merge`

This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see [Section 8.2.1.3, “Index Merge Optimization”](#).

- `unique_subquery`

This type replaces `eq_ref` for some `IN` subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

`unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- `index_subquery`

This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for nonunique indexes in subqueries of the following form:

```
value IN (SELECT key_column FROM single_table WHERE some_expr)
```

- `range`

Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column in the output row indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

`range` can be used when a key column is compared to a constant using any of the `=`, `<>`, `>`, `>=`, `<`, `<=`, `IS NULL`, `<=>`, `BETWEEN`, `LIKE`, or `IN()` operators:

```
SELECT * FROM tbl_name
  WHERE key_column = 10;

SELECT * FROM tbl_name
  WHERE key_column BETWEEN 10 and 20;

SELECT * FROM tbl_name
  WHERE key_column IN (10,20,30);

SELECT * FROM tbl_name
  WHERE key_part1 = 10 AND key_part2 IN (10,20,30);
```

- `index`

The `index` join type is the same as `ALL`, except that the index tree is scanned. This occurs two ways:

- If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the `Extra` column says `Using index`. An index-only scan usually is faster than `ALL` because the size of the index usually is smaller than the table data.
- A full table scan is performed using reads from the index to look up data rows in index order. `Uses index` does not appear in the `Extra` column.

MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually very bad in all other cases. Normally, you can avoid `ALL` by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

EXPLAIN Extra Information

The `Extra` column of `EXPLAIN` output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. Each item also indicates for JSON-formatted output which property displays the `Extra` value. For some of these, there is a specific property. The others display as the text of the `message` property.

If you want to make your queries as fast as possible, look out for `Extra` column values of `Using filesort` and `Using temporary`, or, in JSON-formatted `EXPLAIN` output, for `using_filesort` and `using_temporary_table` properties equal to `true`.

- `Child of 'table' pushed join@1` (JSON: `message` text)

This table is referenced as the child of `table` in a join that can be pushed down to the NDB kernel. Applies only in NDB Cluster, when pushed-down joins are enabled. See the description of the `ndb_join_pushdown` server system variable for more information and examples.

- `const row not found` (JSON property: `const_row_not_found`)

For a query such as `SELECT ... FROM tbl_name`, the table was empty.

- `Deleting all rows` (JSON property: `message`)

For `DELETE`, some storage engines (such as `MyISAM`) support a handler method that removes all table rows in a simple and fast way. This `Extra` value is displayed if the engine uses this optimization.

- `Distinct` (JSON property: `distinct`)

MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- `FirstMatch(tbl_name)` (JSON property: `first_match`)

The semijoin FirstMatch join shortcutting strategy is used for `tbl_name`.

- `Full scan on NULL key` (JSON property: `message`)

This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- Impossible HAVING (JSON property: message)

The HAVING clause is always false and cannot select any rows.

- Impossible WHERE (JSON property: message)

The WHERE clause is always false and cannot select any rows.

- Impossible WHERE noticed after reading const tables (JSON property: message)

MySQL has read all const (and system) tables and notice that the WHERE clause is always false.

- LooseScan(*m*..*n*) (JSON property: message)

The semijoin LooseScan strategy is used. *m* and *n* are key part numbers.

- No matching min/max row (JSON property: message)

No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- no matching row in const table (JSON property: message)

For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- No matching rows after partition pruning (JSON property: message)

For DELETE or UPDATE, the optimizer found nothing to delete or update after partition pruning. It is similar in meaning to Impossible WHERE for SELECT statements.

- No tables used (JSON property: message)

The query has no FROM clause, or has a FROM DUAL clause.

For INSERT or REPLACE statements, EXPLAIN displays this value when there is no SELECT part. For example, it appears for `EXPLAIN INSERT INTO t VALUES(10)` because that is equivalent to `EXPLAIN INSERT INTO t SELECT 10 FROM DUAL`.

- Not exists (JSON property: message)

MySQL was able to do a LEFT JOIN optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the LEFT JOIN criteria. Here is an example of the type of query that can be optimized this way:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
WHERE t2.id IS NULL;
```

Assume that `t2.id` is defined as NOT NULL. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be NULL, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

In MySQL 8.0.17 and later, this can also indicate that a WHERE condition of the form NOT IN (subquery) or NOT EXISTS (subquery) has been transformed internally into an antijoin. This removes the subquery and brings its tables into the plan for the topmost query, providing improved cost planning. By merging semijoins and antijoins, the optimizer can reorder tables in the execution plan more freely, in some cases resulting in a faster plan.

You can see when an antijoin transformation is performed for a given query by checking the Message column from SHOW WARNINGS following execution of EXPLAIN, or in the output of EXPLAIN FORMAT=TREE.

**Note**

An antijoin is the complement of a semijoin `table_a JOIN table_b ON condition`. The antijoin returns all rows from `table_a` for which there is *no* row in `table_b` which matches `condition`.

- `Plan isn't ready yet` (JSON property: `none`)

This value occurs with `EXPLAIN FOR CONNECTION` when the optimizer has not finished creating the execution plan for the statement executing in the named connection. If execution plan output comprises multiple lines, any or all of them could have this `Extra` value, depending on the progress of the optimizer in determining the full execution plan.

- `Range checked for each record (index map: N)` (JSON property: `message`)

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a `range` or `index_merge` access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in [Section 8.2.1.2, “Range Optimization”](#), and [Section 8.2.1.3, “Index Merge Optimization”](#), with the exception that all column values for the preceding table are known and considered to be constants.

Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value `N` is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 will be considered.

- `Recursive` (JSON property: `recursive`)

This indicates that the row applies to the recursive `SELECT` part of a recursive common table expression. See [Section 13.2.15, “WITH \(Common Table Expressions\)”](#).

- `Rematerialize` (JSON property: `rematerialize`)

`Rematerialize (X,...)` is displayed in the `EXPLAIN` row for table `T`, where `X` is any lateral derived table whose rematerialization is triggered when a new row of `T` is read. For example:

```
SELECT
  ...
FROM
  t,
  LATERAL (derived table that refers to t) AS dt
...
```

The content of the derived table is rematerialized to bring it up to date each time a new row of `t` is processed by the top query.

- `Scanned N databases` (JSON property: `message`)

This indicates how many directory scans the server performs when processing a query for `INFORMATION_SCHEMA` tables, as described in [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#). The value of `N` can be 0, 1, or `all`.

- `Select tables optimized away` (JSON property: `message`)

The optimizer determined 1) that at most one row should be returned, and 2) that to produce this row, a deterministic set of rows must be read. When the rows to be read can be read during the

optimization phase (for example, by reading index rows), there is no need to read any tables during query execution.

The first condition is fulfilled when the query is implicitly grouped (contains an aggregate function but no `GROUP BY` clause). The second condition is fulfilled when one row lookup is performed per index used. The number of indexes read determines the number of rows to read.

Consider the following implicitly grouped query:

```
SELECT MIN(c1), MIN(c2) FROM t1;
```

Suppose that `MIN(c1)` can be retrieved by reading one index row and `MIN(c2)` can be retrieved by reading one row from a different index. That is, for each column `c1` and `c2`, there exists an index where the column is the first column of the index. In this case, one row is returned, produced by reading two deterministic rows.

This `Extra` value does not occur if the rows to read are not deterministic. Consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 <= 10;
```

Suppose that `(c1, c2)` is a covering index. Using this index, all rows with `c1 <= 10` must be scanned to find the minimum `c2` value. By contrast, consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 = 10;
```

In this case, the first index row with `c1 = 10` contains the minimum `c2` value. Only one row must be read to produce the returned row.

For storage engines that maintain an exact row count per table (such as `MyISAM`, but not `InnoDB`), this `Extra` value can occur for `COUNT(*)` queries for which the `WHERE` clause is missing or always true and there is no `GROUP BY` clause. (This is an instance of an implicitly grouped query where the storage engine influences whether a deterministic number of rows can be read.)

- `Skip_open_table`, `Open_frm_only`, `Open_full_table` (JSON property: `message`)

These values indicate file-opening optimizations that apply to queries for `INFORMATION_SCHEMA` tables.

- `Skip_open_table`: Table files do not need to be opened. The information is already available from the data dictionary.
- `Open_frm_only`: Only the data dictionary need be read for table information.
- `Open_full_table`: Unoptimized information lookup. Table information must be read from the data dictionary and by reading table files.

- `Start temporary`, `End temporary` (JSON property: `message`)

This indicates temporary table use for the semijoin Duplicate Weedout strategy.

- `unique row not found` (JSON property: `message`)

For a query such as `SELECT ... FROM tbl_name`, no rows satisfy the condition for a `UNIQUE` index or `PRIMARY KEY` on the table.

- `Using filesort` (JSON property: `using_filesort`)

MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order. See [Section 8.2.1.16, “ORDER BY Optimization”](#).

- `Using index` (JSON property: `using_index`)

The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

For InnoDB tables that have a user-defined clustered index, that index can be used even when `Using index` is absent from the `Extra` column. This is the case if `type` is `index` and `key` is `PRIMARY`.

- `Using index condition` (JSON property: `using_index_condition`)

Tables are read by accessing index tuples and testing them first to determine whether to read full table rows. In this way, index information is used to defer (“push down”) reading full table rows unless it is necessary. See [Section 8.2.1.6, “Index Condition Pushdown Optimization”](#).

- `Using index for group-by` (JSON property: `using_index_for_group_by`)

Similar to the `Using index` table access method, `Using index for group-by` indicates that MySQL found an index that can be used to retrieve all columns of a `GROUP BY` or `DISTINCT` query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see [Section 8.2.1.17, “GROUP BY Optimization”](#).

- `Using index for skip scan` (JSON property: `using_index_for_skip_scan`)

Indicates that the Skip Scan access method is used. See [Skip Scan Range Access Method](#).

- `Using join buffer (Block Nested Loop)`, `Using join buffer (Batched Key Access)`, `Using join buffer (hash join)` (JSON property: `using_join_buffer`)

Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table. `(Block Nested Loop)` indicates use of the Block Nested-Loop algorithm, `(Batched Key Access)` indicates use of the Batched Key Access algorithm, and `(hash join)` indicates use of a hash join. That is, the keys from the table on the preceding line of the `EXPLAIN` output are buffered, and the matching rows are fetched in batches from the table represented by the line in which `Using join buffer` appears.

In JSON-formatted output, the value of `using_join_buffer` is always one of `Block Nested Loop`, `Batched Key Access`, or `hash join`.

Hash joins are available beginning with MySQL 8.0.18; the Block Nested-Loop algorithm is not used in MySQL 8.0.20 or later MySQL releases. For more information about these optimizations, see [Section 8.2.1.4, “Hash Join Optimization”](#), and [Block Nested-Loop Join Algorithm](#).

See [Batched Key Access Joins](#), for information about the Batched Key Access algorithm.

- `Using MRR` (JSON property: `message`)

Tables are read using the Multi-Range Read optimization strategy. See [Section 8.2.1.11, “Multi-Range Read Optimization”](#).

- `Using sort_union(...)`, `Using union(...)`, `Using intersect(...)` (JSON property: `message`)

These indicate the particular algorithm showing how index scans are merged for the `index_merge` join type. See [Section 8.2.1.3, “Index Merge Optimization”](#).

- `Using temporary` (JSON property: `using_temporary_table`)

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- `Using where` (JSON property: `attached_condition`)

A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index`.

`Using where` has no direct counterpart in JSON-formatted output; the `attached_condition` property contains any `WHERE` condition used.

- `Using where with pushed condition` (JSON property: `message`)

This item applies to `NDB` tables *only*. It means that NDB Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster's data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see [Section 8.2.1.5, “Engine Condition Pushdown Optimization”](#).

- `Zero limit` (JSON property: `message`)

The query had a `LIMIT 0` clause and cannot select any rows.

EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the `EXPLAIN` output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See [Section 5.1.1, “Configuring the Server”](#).

The following example shows how a multiple-table join can be optimized progressively based on the information provided by `EXPLAIN`.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using `EXPLAIN`:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
              tt.ProjectReference, tt.EstimatedShipDate,
              tt.ActualShipDate, tt.ClientID,
              tt.ServiceCodes, tt.RepetitiveID,
              tt.CurrentProcess, tt.CurrentDPPerson,
              tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
              et_1.COUNTRY, do.CUSTNAME
FROM tt, et, et AS et_1, do
WHERE tt.SubmitTime IS NULL
      AND tt.ActualPC = et.EMPLOYID
      AND tt.AssignedPC = et_1.EMPLOYID
      AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

Table	Column	Data Type
tt	ActualPC	CHAR(10)
tt	AssignedPC	CHAR(10)
tt	ClientID	CHAR(10)
et	EMPLOYID	CHAR(15)
do	CUSTNMBR	CHAR(15)

- The tables have the following indexes.

Table	Index
tt	ActualPC
tt	AssignedPC
tt	ClientID
et	EMPLOYID (primary key)
do	CUSTNMBR (primary key)

- The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

```
table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
do ALL PRIMARY NULL NULL NULL 2135
et_1 ALL PRIMARY NULL NULL NULL 74
tt ALL AssignedPC, NULL NULL NULL 3872
    ClientID,
    ActualPC
    Range checked for each record (index map: 0x23)
```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$ rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

```
table type possible_keys key key_len ref rows Extra
tt ALL AssignedPC, NULL NULL NULL 3872 Using
    ClientID, where
    ActualPC
do ALL PRIMARY NULL NULL NULL 2135
    Range checked for each record (index map: 0x1)
et_1 ALL PRIMARY NULL NULL NULL 74
    Range checked for each record (index map: 0x1)
et eq_ref PRIMARY PRIMARY 15 tt.ActualPC 1
```

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
    MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

```
table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
```

tt	ref	AssignedPC, ClientID, ActualPC	ActualPC	15	et.EMPLOYID	52	Using where
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

table	type	possible_keys	key	key_len	ref	rows	Extra
tt	ALL	AssignedPC, ClientID, ActualPC	NULL	NULL	NULL	3872	Using where
et	eq_ref	PRIMARY	PRIMARY	15	tt.ActualPC	1	
et_1	eq_ref	PRIMARY	PRIMARY	15	tt.AssignedPC	1	
do	eq_ref	PRIMARY	PRIMARY	15	tt.ClientID	1	

The `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. Check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause. (However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semijoin transformations. See [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#).)

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see [Section 13.2.11.8, “Derived Tables”](#).

8.8.3 Extended EXPLAIN Output Format

The `EXPLAIN` statement produces extra (“extended”) information that is not part of `EXPLAIN` output but can be viewed by issuing a `SHOW WARNINGS` statement following `EXPLAIN`. As of MySQL 8.0.12, extended information is available for `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements. Prior to 8.0.12, extended information is available only for `SELECT` statements.

The `Message` value in `SHOW WARNINGS` output displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

The extended information displayable with a `SHOW WARNINGS` statement following `EXPLAIN` is produced only for `SELECT` statements. `SHOW WARNINGS` displays an empty result for other explainable statements (`DELETE`, `INSERT`, `REPLACE`, and `UPDATE`).

Here is an example of extended `EXPLAIN` output:

```
mysql> EXPLAIN
      SELECT t1.a, t1.a IN (SELECT t2.a FROM t2) FROM t1\G
***** 1. row *****
      id: 1
    select_type: PRIMARY
      table: t1
        type: index
possible_keys: NULL
          key: PRIMARY
        key_len: 4
          ref: NULL
        rows: 4
    filtered: 100.00
      Extra: Using index
***** 2. row *****
      id: 2
    select_type: SUBQUERY
```

```

        table: t2
        type: index
possible_keys: a
        key: a
        key_len: 5
        ref: NULL
        rows: 3
        filtered: 100.00
        Extra: Using index
2 rows in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select `test`.`t1`.`a` AS `a`,
      <in_optimizer>(`test`.`t1`.`a`,`test`.`t1`.`a` in
      ( <materialize> (/* select#2 */ select `test`.`t2`.`a`
      from `test`.`t2` where 1 having 1 ),
      <primary_index_lookup>(`test`.`t1`.`a` in
      <temporary table> on <auto_key>
      where ((`test`.`t1`.`a` = `materialized-subquery`.`a`)))) AS `t1.a`
      IN (SELECT t2.a FROM t2)` from `test`.`t1`
1 row in set (0.00 sec)

```

Because the statement displayed by `SHOW WARNINGS` may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with `Message` values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in the extended output displayed by `SHOW WARNINGS`:

- `<auto_key>`

An automatically generated key for a temporary table.

- `<cache>(expr)`

The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use. For results consisting of multiple values, a temporary table may be created and you will see `<temporary table>` instead.

- `<exists>(query fragment)`

The subquery predicate is converted to an `EXISTS` predicate and the subquery is transformed so that it can be used together with the `EXISTS` predicate.

- `<in_optimizer>(query fragment)`

This is an internal optimizer object with no user significance.

- `<index_lookup>(query fragment)`

The query fragment is processed using an index lookup to find qualifying rows.

- `<if>(condition, expr1, expr2)`

If the condition is true, evaluate to `expr1`, otherwise `expr2`.

- `<is_not_null_test>(expr)`

A test to verify that the expression does not evaluate to `NULL`.

- `<materialize>(query fragment)`

Subquery materialization is used.

- ``materialized-subquery`.col_name`

A reference to the column `col_name` in an internal temporary table materialized to hold the result from evaluating a subquery.

- `<primary_index_lookup>(query fragment)`

The query fragment is processed using a primary key lookup to find qualifying rows.

- `<ref_null_helper>(expr)`

This is an internal optimizer object with no user significance.

- `/* select#N */ select_stmt`

The `SELECT` is associated with the row in non-extended `EXPLAIN` output that has an `id` value of `N`.

- `outer_tables semi join (inner_tables)`

A semijoin operation. `inner_tables` shows the tables that were not pulled out. See [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#).

- `<temporary table>`

This represents an internal temporary table created to cache an intermediate result.

When some tables are of `const` or `system` type, expressions involving columns from these tables are evaluated early by the optimizer and are not part of the displayed statement. However, with `FORMAT=JSON`, some `const` table accesses are displayed as a `ref` access that uses a `const` value.

8.8.4 Obtaining Execution Plan Information for a Named Connection

To obtain the execution plan for an explainable statement executing in a named connection, use this statement:

```
EXPLAIN [options] FOR CONNECTION connection_id;
```

`EXPLAIN FOR CONNECTION` returns the `EXPLAIN` information that is currently being used to execute a query in a given connection. Because of changes to data (and supporting statistics) it may produce a different result from running `EXPLAIN` on the equivalent query text. This difference in behavior can be useful in diagnosing more transient performance problems. For example, if you are running a statement in one session that is taking a long time to complete, using `EXPLAIN FOR CONNECTION` in another session may yield useful information about the cause of the delay.

`connection_id` is the connection identifier, as obtained from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `SHOW PROCESSLIST` statement. If you have the `PROCESS` privilege, you can specify the identifier for any connection. Otherwise, you can specify the identifier only for your own connections. In all cases, you must have sufficient privileges to explain the query on the specified connection.

If the named connection is not executing a statement, the result is empty. Otherwise, `EXPLAIN FOR CONNECTION` applies only if the statement being executed in the named connection is explainable. This includes `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE`. (However, `EXPLAIN FOR CONNECTION` does not work for prepared statements, even prepared statements of those types.)

If the named connection is executing an explainable statement, the output is what you would obtain by using `EXPLAIN` on the statement itself.

If the named connection is executing a statement that is not explainable, an error occurs. For example, you cannot name the connection identifier for your current session because `EXPLAIN` is not explainable:

```
mysql> SELECT CONNECTION_ID();
+-----+
```

```
| CONNECTION_ID() |
+-----+
|          373   |
+-----+
1 row in set (0.00 sec)

mysql> EXPLAIN FOR CONNECTION 373;
ERROR 1889 (HY000): EXPLAIN FOR CONNECTION command is supported
only for SELECT/UPDATE/INSERT/DELETE/REPLACE
```

The `Com_explain_other` status variable indicates the number of `EXPLAIN FOR CONNECTION` statements executed.

8.8.5 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row: $\log(\text{row_count}) / \log(\text{index_block_length} / 3 * 2 / (\text{index_length} + \text{data_pointer_length})) + 1$.

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates $\log(500,000) / \log(1024 / 3 * 2 / (3 + 4)) + 1 = 4$ seeks.

This index would require storage of about $500,000 * 7 * 3/2 = 5.2\text{MB}$ (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

The preceding discussion does not mean that your application performance slowly degenerates by $\log N$. As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by $\log N$). To avoid this, increase the key cache size as the data grows. For `MyISAM` tables, the key cache size is controlled by the `key_buffer_size` system variable. See [Section 5.1.1, “Configuring the Server”](#).

8.9 Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated, switchable optimizations, optimizer and index hints, and the optimizer cost model.

The server maintains histogram statistics about column values in the `column_statistics` data dictionary table (see [Section 8.9.6, “Optimizer Statistics”](#)). Like other data dictionary tables, this table is not directly accessible by users. Instead, you can obtain histogram information by querying `INFORMATION_SCHEMA.COLUMN_STATISTICS`, which is implemented as a view on the data dictionary table. You can also perform histogram management using the `ANALYZE TABLE` statement.

8.9.1 Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server’s performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are

investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of “educated guess” rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.
- The `optimizer_search_depth` variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

8.9.2 Switchable Optimizations

The `optimizer_switch` system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,index_merge_intersection=on,
                    engine_condition_pushdown=on,index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,block_nested_loop=on,
                    batched_key_access=off,materialization=on,semijoin=on,
                    loosescan=on,firstmatch=on,duplicateweedout=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on,condition_fanout_filter=on,
                    derived_merge=on,use_invisible_indexes=off,skip_scan=on,
                    hash_join=on,subquery_to_derived=off,
                    prefer_ordering_index=on,hypergraph_optimizer=off,
                    derived_condition_pushdown=on
1 row in set (0.00 sec)
```

To change the value of `optimizer_switch`, assign a value consisting of a comma-separated list of one or more commands:

```
SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';
```

Each `command` value should have one of the forms shown in the following table.

Command Syntax	Meaning
<code>default</code>	Reset every optimization to its default value
<code>opt_name=default</code>	Set the named optimization to its default value
<code>opt_name=off</code>	Disable the named optimization
<code>opt_name=on</code>	Enable the named optimization

The order of the commands in the value does not matter, although the `default` command is executed first if present. Setting an `opt_name` flag to `default` sets it to whichever of `on` or `off` is its default value. Specifying any given `opt_name` more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of `optimizer_switch` unchanged.

The following list describes the permissible `opt_name` flag names, grouped by optimization strategy:

- Batched Key Access Flags

- `batched_key_access` (default `off`)

Controls use of BKA join algorithm.

For `batched_key_access` to have any effect when set to `on`, the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used.

For more information, see [Section 8.2.1.12, “Block Nested-Loop and Batched Key Access Joins”](#).

- Block Nested-Loop Flags

- `block_nested_loop` (default `on`)

Controls use of BNL join algorithm. In MySQL 8.0.18 and later, this also controls use of hash joins, as do the `BNL` and `NO_BNL` optimizer hints. In MySQL 8.0.20 and later, block nested loop support is removed from the MySQL server, and this flag controls the use of hash joins only.

For more information, see [Section 8.2.1.12, “Block Nested-Loop and Batched Key Access Joins”](#).

- Condition Filtering Flags

- `condition_fanout_filter` (default `on`)

Controls use of condition filtering.

For more information, see [Section 8.2.1.13, “Condition Filtering”](#).

- Derived Table Merging Flags

- `derived_merge` (default `on`)

Controls merging of derived tables and views into outer query block.

The `derived_merge` flag controls whether the optimizer attempts to merge derived tables, view references, and common table expressions into the outer query block, assuming that no other rule prevents merging; for example, an `ALGORITHM` directive for a view takes precedence over the `derived_merge` setting. By default, the flag is `on` to enable merging.

For more information, see [Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”](#).

- Derived Condition Pushdown Flags

- `derived_condition_pushdown` (default `on`)

Controls derived condition pushdown.

For more information, see [Section 8.2.2.5, “Derived Condition Pushdown Optimization”](#)

- Engine Condition Pushdown Flags

- `engine_condition_pushdown` (default `on`)

Controls engine condition pushdown.

For more information, see [Section 8.2.1.5, “Engine Condition Pushdown Optimization”](#).

- Hash Join Flags

- `hash_join` (default `on`)

Controls hash joins (MySQL 8.0.18 only; has no effect in MySQL 8.0.19 or later).

For more information, see [Section 8.2.1.4, “Hash Join Optimization”](#).

- Index Condition Pushdown Flags

- `index_condition_pushdown` (default `on`)

Controls index condition pushdown.

For more information, see [Section 8.2.1.6, “Index Condition Pushdown Optimization”](#).

- Index Extensions Flags

- `use_index_extensions` (default `on`)

Controls use of index extensions.

For more information, see [Section 8.3.10, “Use of Index Extensions”](#).

- Index Merge Flags

- `index_merge` (default `on`)

Controls all Index Merge optimizations.

- `index_merge_intersection` (default `on`)

Controls the Index Merge Intersection Access optimization.

- `index_merge_sort_union` (default `on`)

Controls the Index Merge Sort-Union Access optimization.

- `index_merge_union` (default `on`)

Controls the Index Merge Union Access optimization.

For more information, see [Section 8.2.1.3, “Index Merge Optimization”](#).

- Index Visibility Flags

- `use_invisible_indexes` (default `off`)

Controls use of invisible indexes.

For more information, see [Section 8.3.12, “Invisible Indexes”](#).

- Multi-Range Read Flags

- `mrr` (default `on`)

Controls the Multi-Range Read strategy.

- `mrr_cost_based` (default `on`)

Controls use of cost-based MRR if `mrr=on`.

For more information, see [Section 8.2.1.11, “Multi-Range Read Optimization”](#).

- Skip Scan Flags

- `skip_scan` (default `on`)

Controls use of Skip Scan access method.

For more information, see [Skip Scan Range Access Method](#).

- Semijoin Flags

- `semijoin` (default `on`)

Controls all semijoin strategies.

In MySQL 8.0.17 and later, this also applies to the antijoin optimization.

- `duplicateweedout` (default `on`)

Controls the semijoin Duplicate Weedout strategy.

- `firstmatch` (default `on`)

Controls the semijoin FirstMatch strategy.

- `loosescan` (default `on`)

Controls the semijoin LooseScan strategy (not to be confused with Loose Index Scan for `GROUP BY`).

The `semijoin`, `firstmatch`, `loosescan`, and `duplicateweedout` flags enable control over semijoin strategies. The `semijoin` flag controls whether semijoins are used. If it is set to `on`, the `firstmatch` and `loosescan` flags enable finer control over the permitted semijoin strategies.

If the `duplicateweedout` semijoin strategy is disabled, it is not used unless all other applicable strategies are also disabled.

If `semijoin` and `materialization` are both `on`, semijoins also use materialization where applicable. These flags are `on` by default.

For more information, see [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#).

- Subquery Materialization Flags

- `materialization` (default `on`)

Controls materialization (including semijoin materialization).

- `subquery_materialization_cost_based` (default `on`)

Use cost-based materialization choice.

The `materialization` flag controls whether subquery materialization is used. If `semijoin` and `materialization` are both `on`, semijoins also use materialization where applicable. These flags are `on` by default.

The `subquery_materialization_cost_based` flag enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. If the flag is `on` (the default),

the optimizer performs a cost-based choice between subquery materialization and [IN-to-EXISTS](#) subquery transformation if either method could be used. If the flag is `off`, the optimizer chooses subquery materialization over [IN-to-EXISTS](#) subquery transformation.

For more information, see [Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#).

- Subquery Transformation Flags

- `subquery_to_derived` (default `off`)

Beginning with MySQL 8.0.21, the optimizer is able in many cases to transform a scalar subquery in a [SELECT](#), [WHERE](#), [JOIN](#), or [HAVING](#) clause into a left outer joins on a derived table. (Depending on the nullability of the derived table, this can sometimes be simplified further to an inner join.) This can be done for a subquery which meets the following conditions:

- The subquery contains one or more aggregate functions, but no [GROUP BY](#) clause.
- The subquery does not make use of any nondeterministic functions, such as [RAND\(\)](#).
- The subquery is not an [ANY](#) or [ALL](#) subquery which can be rewritten to use [MIN\(\)](#) or [MAX\(\)](#).
- The parent query does not set a user variable, since rewriting it may affect the order of execution, which could lead to unexpected results if the variable is accessed more than once in the same query.
- The subquery should not be correlated, that is, it should not reference a column from a table in the outer query, or contain an aggregate that is evaluated in the outer query.

This optimization can also be applied to a table subquery which is the argument to [IN](#), [NOT IN](#), [EXISTS](#), or [NOT EXISTS](#), that does not contain a [GROUP BY](#).

The default value for this flag is `off`, since, in most cases, enabling this optimization does not produce any noticeable improvement in performance (and in many cases can even make queries run more slowly), but you can enable the optimization by setting the `subquery_to_derived` flag to `on`. It is primarily intended for use in testing.

Example, using a scalar subquery:

```
d
mysql> CREATE TABLE t1(a INT);

mysql> CREATE TABLE t2(a INT);

mysql> INSERT INTO t1 VALUES ROW(1), ROW(2), ROW(3), ROW(4);

mysql> INSERT INTO t2 VALUES ROW(1), ROW(2);

mysql> SELECT * FROM t1
  ->      WHERE t1.a > (SELECT COUNT(a) FROM t2);
+-----+
| a      |
+-----+
|      3 |
|      4 |
+-----+

mysql> SELECT @@optimizer_switch LIKE '%subquery_to_derived=off%';
+-----+
| @@optimizer_switch LIKE '%subquery_to_derived=off%' |
+-----+
|                                                    1 |
+-----+

mysql> EXPLAIN SELECT * FROM t1 WHERE t1.a > (SELECT COUNT(a) FROM t2)\G
```

```

***** 1. row *****

rows: 2
filtered: 100.00
Extra: NULL

```

As can be seen from executing `SHOW WARNINGS` immediately following the second `EXPLAIN` statement, with the optimization enabled, the query `SELECT * FROM t1 WHERE t1.a > (SELECT COUNT(a) FROM t2)` is rewritten in a form similar to what is shown here:

```

SELECT t1.a FROM t1
JOIN ( SELECT COUNT(t2.a) AS c FROM t2 ) AS d
WHERE t1.a > d.c;

```

Example, using a query with `IN (subquery)`:

```

mysql> DROP TABLE IF EXISTS t1, t2;

mysql> CREATE TABLE t1 (a INT, b INT);
mysql> CREATE TABLE t2 (a INT, b INT);

mysql> INSERT INTO t1 VALUES ROW(1,10), ROW(2,20), ROW(3,30);
mysql> INSERT INTO t2
-> VALUES ROW(1,10), ROW(2,20), ROW(3,30), ROW(1,110), ROW(2,120), ROW(3,130);

mysql> SELECT * FROM t1
-> WHERE t1.b < 0
-> OR
-> t1.a IN (SELECT t2.a + 1 FROM t2);
+-----+-----+
| a     | b     |
+-----+-----+
| 2     | 20    |
| 3     | 30    |
+-----+-----+

mysql> SET @@optimizer_switch="subquery_to_derived=off";

mysql> EXPLAIN SELECT * FROM t1
-> WHERE t1.b < 0
-> OR
-> t1.a IN (SELECT t2.a + 1 FROM t2)\G
***** 1. row *****

        rows: 6
        filtered: 100.00
        Extra: Using temporary

```

Checking and simplifying the result of `SHOW WARNINGS` after executing `EXPLAIN` on this query shows that, when the `subquery_to_derived` flag enabled, `SELECT * FROM t1 WHERE t1.b < 0 OR t1.a IN (SELECT t2.a + 1 FROM t2)` is rewritten in a form similar to what is shown here:

```

SELECT a, b FROM t1
  LEFT JOIN (SELECT DISTINCT a + 1 AS e FROM t2) d
    ON t1.a = d.e
 WHERE   t1.b < 0
        OR
        d.e IS NOT NULL;

```

Example, using a query with `EXISTS` (*subquery*) and the same tables and data as in the previous example:

```

mysql> SELECT * FROM t1
->          WHERE    t1.b < 0
->
->          OR
->          EXISTS(SELECT * FROM t2 WHERE t2.a = t1.a + 1);
+-----+-----+

```

a	b
1	10
2	20

```

mysql> SET @@optimizer_switch="subquery_to_derived=off";

mysql> EXPLAIN SELECT * FROM t1
      ->          WHERE    t1.b < 0
      ->          OR
      ->          EXISTS(SELECT * FROM t2 WHERE t2.a = t1.a + 1)\G
***** 1. row *****

     key_len: NULL
       ref: NULL
        rows: 6
   filtered: 100.00
    Extra: Using temporary

```

If we execute `SHOW WARNINGS` after running `EXPLAIN` on the query `SELECT * FROM t1 WHERE t1.b < 0 OR EXISTS(SELECT * FROM t2 WHERE t2.a = t1.a + 1)` when `subquery_to_derived` has been enabled, and simplify the second row of the result, we see that it has been rewritten in a form which resembles this:

```

SELECT a, b FROM t1
LEFT JOIN (SELECT DISTINCT 1 AS e1, t2.a AS e2 FROM t2) d
ON t1.a + 1 = d.e2
WHERE  t1.b < 0
      OR
      d.e1 IS NOT NULL;

```

For more information, see [Section 8.2.2.4, “Optimizing Derived Tables, View References, and Common Table Expressions with Merging or Materialization”](#), as well as [Section 8.2.1.19, “LIMIT Query Optimization”](#), and [Section 8.2.2.1, “Optimizing IN and EXISTS Subquery Predicates with Semijoin Transformations”](#).

- Limit Optimization Flags

- `prefer_ordering_index` (default `on`)

Controls whether, in the case of a query having an `ORDER BY` or `GROUP BY` with a `LIMIT` clause, the optimizer tries to use an ordered index instead of an unordered index, a filesort, or some other optimization. This optimization is performed by default whenever the optimizer determines that using it would allow for faster execution of the query.

Because the algorithm that makes this determination cannot handle every conceivable case (due in part to the assumption that the distribution of data is always more or less uniform), there are cases in which this optimization may not be desirable. Prior to MySQL 8.0.21, it was not possible to disable this optimization, but in MySQL 8.0.21 and later, while it remains the default behavior, it can be disabled by setting the `prefer_ordering_index` flag to `off`.

For more information and examples, see [Section 8.2.1.19, “LIMIT Query Optimization”](#).

- Experimental Flags

- `hypergraph_optimizer` (default `off`)

Cannot be enabled in standard releases; attempting to do so results in an error. Used in debug builds for testing purposes.

Added in MySQL 8.0.22.

When you assign a value to `optimizer_switch`, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```

mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,index_merge_intersection=on,

```

```
engine_condition_pushdown=on,index_condition_pushdown=on,
mrr=on,mrr_cost_based=on,block_nested_loop=on,
batched_key_access=off,materialization=on,semijoin=on,
loosescan=on, firstmatch=on,
subquery_materialization_cost_based=on,
use_index_extensions=on,condition_fanout_filter=on,
derived_merge=on,use_invisible_indexes=off,skip_scan=on,
hash_join=on,subquery_to_derived=off,
prefer_ordering_index=on
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer will perform better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';

mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=off,
                    index_merge_sort_union=off,index_merge_intersection=on,
                    engine_condition_pushdown=on,index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,block_nested_loop=on,
                    batched_key_access=off,materialization=on,semijoin=on,
                    loosescan=on, firstmatch=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on,condition_fanout_filter=on,
                    derived_merge=on,use_invisible_indexes=off,skip_scan=on,
                    hash_join=on,subquery_to_derived=off,
                    prefer_ordering_index=on
```

8.9.3 Optimizer Hints

One means of control over optimizer strategies is to set the `optimizer_switch` system variable (see [Section 8.9.2, “Switchable Optimizations”](#)). Changes to this variable affect execution of all subsequent queries; to affect one query differently from another, it is necessary to change `optimizer_switch` before each one.

Another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. Because optimizer hints apply on a per-statement basis, they provide finer control over statement execution plans than can be achieved using `optimizer_switch`. For example, you can enable an optimization for one table in a statement and disable the optimization for a different table. Hints within a statement take precedence over `optimizer_switch` flags.

Examples:

```
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
  FROM t3 WHERE f1 > 30 AND f1 < 33;
SELECT /*+ BKA(t1) NO_BKA(t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ NO_ICP(t1, t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ SEMIJOIN(FIRSTMATCH, LOOSECAN) */ * FROM t1 ...;
EXPLAIN SELECT /*+ NO_ICP(t1) */ * FROM t1 WHERE ...;
SELECT /*+ MERGE(dt) */ * FROM (SELECT * FROM t1) AS dt;
INSERT /*+ SET_VAR(foreign_key_checks=OFF) */ INTO t2 VALUES(2);
```

Optimizer hints, described here, differ from index hints, described in [Section 8.9.4, “Index Hints”](#). Optimizer and index hints may be used separately or together.

- [Optimizer Hint Overview](#)
- [Optimizer Hint Syntax](#)
- [Join-Order Optimizer Hints](#)
- [Table-Level Optimizer Hints](#)
- [Index-Level Optimizer Hints](#)

- [Subquery Optimizer Hints](#)
- [Statement Execution Time Optimizer Hints](#)
- [Variable-Setting Hint Syntax](#)
- [Resource Group Hint Syntax](#)
- [Optimizer Hints for Naming Query Blocks](#)

Optimizer Hint Overview

Optimizer hints apply at different scope levels:

- Global: The hint affects the entire statement
- Query block: The hint affects a particular query block within a statement
- Table-level: The hint affects a particular table within a query block
- Index-level: The hint affects a particular index within a table

The following table summarizes the available optimizer hints, the optimizer strategies they affect, and the scope or scopes at which they apply. More details are given later.

Table 8.2 Optimizer Hints Available

Hint Name	Description	Applicable Scopes
BKA , NO_BKA	Affects Batched Key Access join processing	Query block, table
BNL , NO_BNL	Prior to MySQL 8.0.20: affects Block Nested-Loop join processing; MySQL 8.0.18 and later: also affects hash join optimization; MySQL 8.0.20 and later: affects hash join optimization only	Query block, table
DERIVED_CONDITION_PUSHDOWN , NO_DERIVED_CONDITION_PUSHDOWN	Use, or ignore the derived condition pushdown optimization for materialized derived tables (Added in MySQL 8.0.22)	Query block, table
GROUP_INDEX , NO_GROUP_INDEX	Use or ignore the specified index or indexes for index scans in GROUP BY operations (Added in MySQL 8.0.20)	Index
HASH_JOIN , NO_HASH_JOIN	Affects Hash Join optimization (MySQL 8.0.18 only)	Query block, table
INDEX , NO_INDEX	Acts as the combination of JOIN_INDEX , GROUP_INDEX , and ORDER_INDEX , or as the combination of NO_JOIN_INDEX , NO_GROUP_INDEX , and NO_ORDER_INDEX (Added in MySQL 8.0.20)	Index
INDEX_MERGE , NO_INDEX_MERGE	Affects Index Merge optimization	Table, index
JOIN_FIXED_ORDER	Use table order specified in FROM clause for join order	Query block
JOIN_INDEX , NO_JOIN_INDEX	Use or ignore the specified index or indexes for any access method (Added in MySQL 8.0.20)	Index

Hint Name	Description	Applicable Scopes
JOIN_ORDER	Use table order specified in hint for join order	Query block
JOIN_PREFIX	Use table order specified in hint for first tables of join order	Query block
JOIN_SUFFIX	Use table order specified in hint for last tables of join order	Query block
MAX_EXECUTION_TIME	Limits statement execution time	Global
MERGE , NO_MERGE	Affects derived table/view merging into outer query block	Table
MRR , NO_MRR	Affects Multi-Range Read optimization	Table, index
NO_ICP	Affects Index Condition Pushdown optimization	Table, index
NO_RANGE_OPTIMIZATION	Affects range optimization	Table, index
ORDER_INDEX , NO_ORDER_INDEX	Use or ignore the specified index or indexes for sorting rows (Added in MySQL 8.0.20)	Index
QB_NAME	Assigns name to query block	Query block
RESOURCE_GROUP	Set resource group during statement execution	Global
SEMIJOIN , NO_SEMIJOIN	Affects semijoin strategies; beginning with MySQL 8.0.17, this also applies to antijoins	Query block
SKIP_SCAN , NO_SKIP_SCAN	Affects Skip Scan optimization	Table, index
SET_VAR	Set variable during statement execution	Global
SUBQUERY	Affects materialization, IN-to-EXISTS subquery strategies	Query block

Disabling an optimization prevents the optimizer from using it. Enabling an optimization means the optimizer is free to use the strategy if it applies to statement execution, not that the optimizer necessarily will use it.

Optimizer Hint Syntax

MySQL supports comments in SQL statements as described in [Section 9.6, “Comment Syntax”](#). Optimizer hints must be specified within `/*+ ... */` comments. That is, optimizer hints use a variant of `/* ... */` C-style comment syntax, with a `+` character following the `/*` comment opening sequence. Examples:

```
/*+ BKA(t1) */
/*+ BNL(t1, t2) */
/*+ NO_RANGE_OPTIMIZATION(t4 PRIMARY) */
/*+ QB_NAME(qb2) */
```

Whitespace is permitted after the `+` character.

The parser recognizes optimizer hint comments after the initial keyword of [SELECT](#), [UPDATE](#), [INSERT](#), [REPLACE](#), and [DELETE](#) statements. Hints are permitted in these contexts:

- At the beginning of query and data change statements:

```
SELECT /*+ ... */ ...
INSERT /*+ ... */ ...
REPLACE /*+ ... */ ...
```

```
UPDATE /*+ ... */ ...
DELETE /*+ ... */ ...
```

- At the beginning of query blocks:

```
(SELECT /*+ ... */ ... )
(SELECT ... ) UNION (SELECT /*+ ... */ ... )
(SELECT /*+ ... */ ... ) UNION (SELECT /*+ ... */ ... )
UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
INSERT ... SELECT /*+ ... */ ...
```

- In hintable statements prefaced by [EXPLAIN](#). For example:

```
EXPLAIN SELECT /*+ ... */ ...
EXPLAIN UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
```

The implication is that you can use [EXPLAIN](#) to see how optimizer hints affect execution plans. Use [SHOW WARNINGS](#) immediately after [EXPLAIN](#) to see how hints are used. The extended [EXPLAIN](#) output displayed by a following [SHOW WARNINGS](#) indicates which hints were used. Ignored hints are not displayed.

A hint comment may contain multiple hints, but a query block cannot contain multiple hint comments. This is valid:

```
SELECT /*+ BNL(t1) BKA(t2) */ ...
```

But this is invalid:

```
SELECT /*+ BNL(t1) */ /* BKA(t2) */ ...
```

When a hint comment contains multiple hints, the possibility of duplicates and conflicts exists. The following general guidelines apply. For specific hint types, additional rules may apply, as indicated in the hint descriptions.

- Duplicate hints: For a hint such as `/*+ MRR(idx1) MRR(idx1) */`, MySQL uses the first hint and issues a warning about the duplicate hint.
- Conflicting hints: For a hint such as `/*+ MRR(idx1) NO_MRR(idx1) */`, MySQL uses the first hint and issues a warning about the second conflicting hint.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see [Section 9.2, “Schema Object Names”](#)).

Hint names, query block names, and strategy names are not case sensitive. References to table and index names follow the usual identifier case sensitivity rules (see [Section 9.2.3, “Identifier Case Sensitivity”](#)).

Join-Order Optimizer Hints

Join-order hints affect the order in which the optimizer joins tables.

Syntax of the [JOIN_FIXED_ORDER](#) hint:

```
hint_name([@query_block_name])
```

Syntax of other join-order hints:

```
hint_name([@query_block_name] tbl_name [, tbl_name] ...)
hint_name(tbl_name[@query_block_name] [, tbl_name[@query_block_name]] ...)
```

The syntax refers to these terms:

- [hint_name](#): These hint names are permitted:

- **JOIN_FIXED_ORDER**: Force the optimizer to join tables using the order in which they appear in the **FROM** clause. This is the same as specifying **SELECT STRAIGHT_JOIN**.
- **JOIN_ORDER**: Instruct the optimizer to join tables using the specified table order. The hint applies to the named tables. The optimizer may place tables that are not named anywhere in the join order, including between specified tables.
- **JOIN_PREFIX**: Instruct the optimizer to join tables using the specified table order for the first tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables after the named tables.
- **JOIN_SUFFIX**: Instruct the optimizer to join tables using the specified table order for the last tables of the join execution plan. The hint applies to the named tables. The optimizer places all other tables before the named tables.
- **tbl_name**: The name of a table used in the statement. A hint that names tables applies to all tables that it names. The **JOIN_FIXED_ORDER** hint names no tables and applies to all tables in the **FROM** clause of the query block in which it occurs.

If a table has an alias, hints must refer to the alias, not the table name.

Table names in hints cannot be qualified with schema names.

- **query_block_name**: The query block to which the hint applies. If the hint includes no leading **@query_block_name**, the hint applies to the query block in which it occurs. For **tbl_name@query_block_name** syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

Example:

```
SELECT
/*+ JOIN_PREFIX(t2, t5@subq2, t4@subq1)
   JOIN_ORDER(t4@subq1, t3)
   JOIN_SUFFIX(t1) */
COUNT(*) FROM t1 JOIN t2 JOIN t3
      WHERE t1.f1 IN (SELECT /*+ QB_NAME(subq1) */ f1 FROM t4)
      AND t2.f1 IN (SELECT /*+ QB_NAME(subq2) */ f1 FROM t5);
```

Hints control the behavior of semijoin tables that are merged to the outer query block. If subqueries **subq1** and **subq2** are converted to semijoins, tables **t4@subq1** and **t5@subq2** are merged to the outer query block. In this case, the hint specified in the outer query block controls the behavior of **t4@subq1**, **t5@subq2** tables.

The optimizer resolves join-order hints according to these principles:

- Multiple hint instances

Only one **JOIN_PREFIX** and **JOIN_SUFFIX** hint of each type are applied. Any later hints of the same type are ignored with a warning. **JOIN_ORDER** can be specified several times.

Examples:

```
/*+ JOIN_PREFIX(t1) JOIN_PREFIX(t2) */
```

The second **JOIN_PREFIX** hint is ignored with a warning.

```
/*+ JOIN_PREFIX(t1) JOIN_SUFFIX(t2) */
```

Both hints are applicable. No warning occurs.

```
/*+ JOIN_ORDER(t1, t2) JOIN_ORDER(t2, t3) */
```

Both hints are applicable. No warning occurs.

- Conflicting hints

In some cases hints can conflict, such as when `JOIN_ORDER` and `JOIN_PREFIX` have table orders that are impossible to apply at the same time:

```
SELECT /*+ JOIN_ORDER(t1, t2) JOIN_PREFIX(t2, t1) */ ... FROM t1, t2;
```

In this case, the first specified hint is applied and subsequent conflicting hints are ignored with no warning. A valid hint that is impossible to apply is silently ignored with no warning.

- Ignored hints

A hint is ignored if a table specified in the hint has a circular dependency.

Example:

```
/*+ JOIN_ORDER(t1, t2) JOIN_PREFIX(t2, t1) */
```

The `JOIN_ORDER` hint sets table `t2` dependent on `t1`. The `JOIN_PREFIX` hint is ignored because table `t1` cannot be dependent on `t2`. Ignored hints are not displayed in extended `EXPLAIN` output.

- Interaction with `const` tables

The MySQL optimizer places `const` tables first in the join order, and the position of a `const` table cannot be affected by hints. References to `const` tables in join-order hints are ignored, although the hint is still applicable. For example, these are equivalent:

```
JOIN_ORDER(t1, const_tbl, t2)
JOIN_ORDER(t1, t2)
```

Accepted hints shown in extended `EXPLAIN` output include `const` tables as they were specified.

- Interaction with types of join operations

MySQL supports several type of joins: `LEFT`, `RIGHT`, `INNER`, `CROSS`, `STRAIGHT_JOIN`. A hint that conflicts with the specified type of join is ignored with no warning.

Example:

```
SELECT /*+ JOIN_PREFIX(t1, t2) */FROM t2 LEFT JOIN t1;
```

Here a conflict occurs between the requested join order in the hint and the order required by the `LEFT JOIN`. The hint is ignored with no warning.

Table-Level Optimizer Hints

Table-level hints affect:

- Use of the Block Nested-Loop (BNL) and Batched Key Access (BKA) join-processing algorithms (see [Section 8.2.1.12, “Block Nested-Loop and Batched Key Access Joins”](#)).
- Whether derived tables, view references, or common table expressions should be merged into the outer query block, or materialized using an internal temporary table.
- Use of the derived table condition pushdown optimization (added in MySQL 8.0.22). See [Section 8.2.2.5, “Derived Condition Pushdown Optimization”](#).

These hint types apply to specific tables, or all tables in a query block.

Syntax of table-level hints:

```
hint_name([@query_block_name] [tbl_name [, tbl_name] ...])
hint_name([tbl_name@query_block_name [, tbl_name@query_block_name] ...])
```

The syntax refers to these terms:

- *hint_name*: These hint names are permitted:
 - *BAK*, *NO_BAK*: Enable or disable batched key access for the specified tables.
 - *BNL*, *NO_BNL*: Enable or disable block nested loop for the specified tables. In MySQL 8.0.18 and later, these hints also enable and disable the hash join optimization.

Note

The block-nested loop optimization is removed in MySQL 8.0.20 and later releases, but these hints continue to be supported for enabling and disabling hash joins.

- *DERIVED_CONDITION_PUSHDOWN*, *NO_DERIVED_CONDITION_PUSHDOWN*: Enable or disable use of derived table condition pushdown for the specified tables (added in MySQL 8.0.22). For more information, see [Section 8.2.2.5, “Derived Condition Pushdown Optimization”](#).
- *HASH_JOIN*, *NO_HASH_JOIN*: Enable or disable use of a hash join for the specified tables (MySQL 8.0.18 only; has no effect in MySQL 8.0.19 or later).
- *MERGE*, *NO_MERGE*: Enable merging for the specified tables, view references or common table expressions; or disable merging and use materialization instead.

Note

To use a block nested loop or batched key access hint to enable join buffering for any inner table of an outer join, join buffering must be enabled for all inner tables of the outer join.

- *tbl_name*: The name of a table used in the statement. The hint applies to all tables that it names. If the hint names no tables, it applies to all tables of the query block in which it occurs.

If a table has an alias, hints must refer to the alias, not the table name.

Table names in hints cannot be qualified with schema names.

- *query_block_name*: The query block to which the hint applies. If the hint includes no leading *@query_block_name*, the hint applies to the query block in which it occurs. For *tbl_name@query_block_name* syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

Examples:

```
SELECT /*+ NO_BAK(t1, t2) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_BNL() BAK(t1) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_MERGE(dt) */ * FROM (SELECT * FROM t1) AS dt;
```

A table-level hint applies to tables that receive records from previous tables, not sender tables. Consider this statement:

```
SELECT /*+ BNL(t2) */ FROM t1, t2;
```

If the optimizer chooses to process *t1* first, it applies a Block Nested-Loop join to *t2* by buffering the rows from *t1* before starting to read from *t2*. If the optimizer instead chooses to process *t2* first, the hint has no effect because *t2* is a sender table.

For the *MERGE* and *NO_MERGE* hints, these precedence rules apply:

- A hint takes precedence over any optimizer heuristic that is not a technical constraint. (If providing a hint as a suggestion has no effect, the optimizer has a reason for ignoring it.)

- A hint takes precedence over the `derived_merge` flag of the `optimizer_switch` system variable.
- For view references, an `ALGORITHM={MERGE|TEMPTABLE}` clause in the view definition takes precedence over a hint specified in the query referencing the view.

Index-Level Optimizer Hints

Index-level hints affect which index-processing strategies the optimizer uses for particular tables or indexes. These hint types affect use of Index Condition Pushdown (ICP), Multi-Range Read (MRR), Index Merge, and range optimizations (see [Section 8.2.1, “Optimizing SELECT Statements”](#)).

Syntax of index-level hints:

```
hint_name([@query_block_name] tbl_name [index_name [, index_name] ...])
hint_name(tbl_name@query_block_name [index_name [, index_name] ...])
```

The syntax refers to these terms:

- `hint_name`: These hint names are permitted:
 - `GROUP_INDEX`, `NO_GROUP_INDEX`: Enable or disable the specified index or indexes for index scans for `GROUP BY` operations. Equivalent to the index hints `FORCE INDEX FOR GROUP BY`, `IGNORE INDEX FOR GROUP BY`. Available in MySQL 8.0.20 and later.
 - `INDEX`, `NO_INDEX`: Acts as the combination of `JOIN_INDEX`, `GROUP_INDEX`, and `ORDER_INDEX`, forcing the server to use the specified index or indexes for any and all scopes, or as the combination of `NO_JOIN_INDEX`, `NO_GROUP_INDEX`, and `NO_ORDER_INDEX`, which causes the server to ignore the specified index or indexes for any and all scopes. Equivalent to `FORCE INDEX`, `IGNORE INDEX`. Available beginning with MySQL 8.0.20.
 - `INDEX_MERGE`, `NO_INDEX_MERGE`: Enable or disable the Index Merge access method for the specified table or indexes. For information about this access method, see [Section 8.2.1.3, “Index Merge Optimization”](#). These hints apply to all three Index Merge algorithms.

The `INDEX_MERGE` hint forces the optimizer to use Index Merge for the specified table using the specified set of indexes. If no index is specified, the optimizer considers all possible index combinations and selects the least expensive one. The hint may be ignored if the index combination is inapplicable to the given statement.

The `NO_INDEX_MERGE` hint disables Index Merge combinations that involve any of the specified indexes. If the hint specifies no indexes, Index Merge is not permitted for the table.

- `JOIN_INDEX`, `NO_JOIN_INDEX`: Forces MySQL to use or ignore the specified index or indexes for any access method, such as `ref`, `range`, `index_merge`, and so on. Equivalent to `FORCE INDEX FOR JOIN`, `IGNORE INDEX FOR JOIN`. Available in MySQL 8.0.20 and later.
- `MRR`, `NO_MRR`: Enable or disable MRR for the specified table or indexes. MRR hints apply only to InnoDB and MyISAM tables. For information about this access method, see [Section 8.2.1.11, “Multi-Range Read Optimization”](#).
- `NO_ICP`: Disable ICP for the specified table or indexes. By default, ICP is a candidate optimization strategy, so there is no hint for enabling it. For information about this access method, see [Section 8.2.1.6, “Index Condition Pushdown Optimization”](#).
- `NO_RANGE_OPTIMIZATION`: Disable index range access for the specified table or indexes. This hint also disables Index Merge and Loose Index Scan for the table or indexes. By default, range access is a candidate optimization strategy, so there is no hint for enabling it.

This hint may be useful when the number of ranges may be high and range optimization would require many resources.

- `ORDER_INDEX`, `NO_ORDER_INDEX`: Cause MySQL to use or to ignore the specified index or indexes for sorting rows. Equivalent to `FORCE INDEX FOR ORDER BY`, `IGNORE INDEX FOR ORDER BY`. Available beginning with MySQL 8.0.20.
- `SKIP_SCAN`, `NO_SKIP_SCAN`: Enable or disable the Skip Scan access method for the specified table or indexes. For information about this access method, see [Skip Scan Range Access Method](#). These hints are available as of MySQL 8.0.13.

The `SKIP_SCAN` hint forces the optimizer to use Skip Scan for the specified table using the specified set of indexes. If no index is specified, the optimizer considers all possible indexes and selects the least expensive one. The hint may be ignored if the index is inapplicable to the given statement.

The `NO_SKIP_SCAN` hint disables Skip Scan for the specified indexes. If the hint specifies no indexes, Skip Scan is not permitted for the table.

- `tbl_name`: The table to which the hint applies.
- `index_name`: The name of an index in the named table. The hint applies to all indexes that it names. If the hint names no indexes, it applies to all indexes in the table.

To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use `SHOW INDEX`.

- `query_block_name`: The query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. For `tbl_name@query_block_name` syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

Examples:

```
SELECT /*+ INDEX_MERGE(t1 f3, PRIMARY) */ f2 FROM t1
  WHERE f1 = 'o' AND f2 = f3 AND f3 <= 4;
SELECT /*+ MRR(t1) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
  FROM t3 WHERE f1 > 30 AND f1 < 33;
INSERT INTO t3(f1, f2, f3)
  (SELECT /*+ NO_ICP(t2) */ t2.f1, t2.f2, t2.f3 FROM t1,t2
   WHERE t1.f1=t2.f1 AND t2.f2 BETWEEN t1.f1
     AND t1.f2 AND t2.f2 + 1 >= t1.f1 + 1);
SELECT /*+ SKIP_SCAN(t1 PRIMARY) */ f1, f2
  FROM t1 WHERE f2 > 40;
```

The following examples use the Index Merge hints, but other index-level hints follow the same principles regarding hint ignoring and precedence of optimizer hints in relation to the `optimizer_switch` system variable or index hints.

Assume that table `t1` has columns `a`, `b`, `c`, and `d`; and that indexes named `i_a`, `i_b`, and `i_c` exist on `a`, `b`, and `c`, respectively:

```
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c)*/ * FROM t1
  WHERE a = 1 AND b = 2 AND c = 3 AND d = 4;
```

Index Merge is used for (`i_a`, `i_b`, `i_c`) in this case.

```
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c)*/ * FROM t1
  WHERE b = 1 AND c = 2 AND d = 3;
```

Index Merge is used for (`i_b`, `i_c`) in this case.

```
/*+ INDEX_MERGE(t1 i_a, i_b) NO_INDEX_MERGE(t1 i_b) */
```

`NO_INDEX_MERGE` is ignored because there is a preceding hint for the same table.

```
/*+ NO_INDEX_MERGE(t1 i_a, i_b) INDEX_MERGE(t1 i_b) */
```

`INDEX_MERGE` is ignored because there is a preceding hint for the same table.

For the `INDEX_MERGE` and `NO_INDEX_MERGE` optimizer hints, these precedence rules apply:

- If an optimizer hint is specified and is applicable, it takes precedence over the Index Merge-related flags of the `optimizer_switch` system variable.

```
SET optimizer_switch='index_merge_intersection=off';
SELECT /*+ INDEX_MERGE(t1 i_b, i_c) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

The hint takes precedence over `optimizer_switch`. Index Merge is used for `(i_b, i_c)` in this case.

```
SET optimizer_switch='index_merge_intersection=on';
SELECT /*+ INDEX_MERGE(t1 i_b) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

The hint specifies only one index, so it is inapplicable, and the `optimizer_switch` flag (`on`) applies. Index Merge is used if the optimizer assesses it to be cost efficient.

```
SET optimizer_switch='index_merge_intersection=off';
SELECT /*+ INDEX_MERGE(t1 i_b) */ * FROM t1
WHERE b = 1 AND c = 2 AND d = 3;
```

The hint specifies only one index, so it is inapplicable, and the `optimizer_switch` flag (`off`) applies. Index Merge is not used.

- The index-level optimizer hints `GROUP_INDEX`, `INDEX`, `JOIN_INDEX`, and `ORDER_INDEX` all take precedence over the equivalent `FORCE INDEX` hints; that is, they cause the `FORCE INDEX` hints to be ignored. Likewise, the `NO_GROUP_INDEX`, `NO_INDEX`, `NO_JOIN_INDEX`, and `NO_ORDER_INDEX` hints all take precedence over any `IGNORE INDEX` equivalents, also causing them to be ignored.

The index-level optimizer hints `GROUP_INDEX`, `NO_GROUP_INDEX`, `INDEX`, `NO_INDEX`, `JOIN_INDEX`, `NO_JOIN_INDEX`, `ORDER_INDEX`, and `NO_ORDER_INDEX` hints all take precedence over all other optimizer hints, including other index-level optimizer hints. Any other optimizer hints are applied only to the indexes permitted by these.

The `GROUP_INDEX`, `INDEX`, `JOIN_INDEX`, and `ORDER_INDEX` hints are all equivalent to `FORCE INDEX` and not to `USE INDEX`. This is because using one or more of these hints means that a table scan is used only if there is no way to use one of the named indexes to find rows in the table. To cause MySQL to use the same index or set of indexes as with a given instance of `USE INDEX`, you can use `NO_INDEX`, `NO_JOIN_INDEX`, `NO_GROUP_INDEX`, `NO_ORDER_INDEX`, or some combination of these.

To replicate the effect that `USE INDEX` has in the query `SELECT a,c FROM t1 USE INDEX FOR ORDER BY (i_a) ORDER BY a`, you can use the `NO_ORDER_INDEX` optimizer hint to cover all indexes on the table except the one that is desired like this:

```
SELECT /*+ NO_ORDER_INDEX(t1 i_b,i_c) */ a,c
FROM t1
ORDER BY a;
```

Attempting to combine `NO_ORDER_INDEX` for the table as a whole with `USE INDEX FOR ORDER BY` does not work to do this, because `NO_ORDER_BY` causes `USE INDEX` to be ignored, as shown here:

```
mysql> EXPLAIN SELECT /*+ NO_ORDER_INDEX(t1) */ a,c FROM t1
->      USE INDEX FOR ORDER BY (i_a) ORDER BY a\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: t1
```

```

partitions: NULL
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: 256
filtered: 100.00
Extra: Using filesort

```

- The `USE INDEX`, `FORCE INDEX`, and `IGNORE INDEX` index hints have higher priority than the `INDEX_MERGE` and `NO_INDEX_MERGE` optimizer hints.

```
/*+ INDEX_MERGE(t1 i_a, i_b, i_c) */ ... IGNORE INDEX i_a
```

`IGNORE INDEX` takes precedence over `INDEX_MERGE`, so index `i_a` is excluded from the possible ranges for Index Merge.

```
/*+ NO_INDEX_MERGE(t1 i_a, i_b) */ ... FORCE INDEX i_a, i_b
```

Index Merge is disallowed for `i_a`, `i_b` because of `FORCE INDEX`, but the optimizer is forced to use either `i_a` or `i_b` for `range` or `ref` access. There are no conflicts; both hints are applicable.

- If an `IGNORE INDEX` hint names multiple indexes, those indexes are unavailable for Index Merge.
- The `FORCE INDEX` and `USE INDEX` hints make only the named indexes to be available for Index Merge.

```
SELECT /*+ INDEX_MERGE(t1 i_a, i_b, i_c) */ a FROM t1
FORCE INDEX (i_a, i_b) WHERE c = 'h' AND a = 2 AND b = 'b';
```

The Index Merge intersection access algorithm is used for `(i_a, i_b)`. The same is true if `FORCE INDEX` is changed to `USE INDEX`.

Subquery Optimizer Hints

Subquery hints affect whether to use semijoin transformations and which semijoin strategies to permit, and, when semijoins are not used, whether to use subquery materialization or `IN-to-EXISTS` transformations. For more information about these optimizations, see [Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#).

Syntax of hints that affect semijoin strategies:

```
hint_name([@query_block_name] [strategy [, strategy] ...])
```

The syntax refers to these terms:

- `hint_name`: These hint names are permitted:
 - `SEMIJOIN`, `NO_SEMIJOIN`: Enable or disable the named semijoin strategies.
- `strategy`: A semijoin strategy to be enabled or disabled. These strategy names are permitted: `DUPSWEEDOUT`, `FIRSTMATCH`, `LOOESCAN`, `MATERIALIZATION`.

For `SEMIJOIN` hints, if no strategies are named, semijoin is used if possible based on the strategies enabled according to the `optimizer_switch` system variable. If strategies are named but inapplicable for the statement, `DUPSWEEDOUT` is used.

For `NO_SEMIJOIN` hints, if no strategies are named, semijoin is not used. If strategies are named that rule out all applicable strategies for the statement, `DUPSWEEDOUT` is used.

If one subquery is nested within another and both are merged into a semijoin of an outer query, any specification of semijoin strategies for the innermost query are ignored. `SEMIJOIN` and `NO_SEMIJOIN` hints can still be used to enable or disable semijoin transformations for such nested subqueries.

If `DUPSWEEDOUT` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

Examples:

```
SELECT /*+ NO_SEMIJOIN(@subq1 FIRSTMATCH, LOOSES SCAN) */ * FROM t2
  WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
SELECT /*+ SEMIJOIN(@subq1 MATERIALIZATION, DUPSWEEDOUT) */ * FROM t2
  WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
```

Syntax of hints that affect whether to use subquery materialization or `IN-to-EXISTS` transformations:

```
SUBQUERY([@query_block_name] strategy)
```

The hint name is always `SUBQUERY`.

For `SUBQUERY` hints, these *strategy* values are permitted: `INTOEXISTS`, `MATERIALIZATION`.

Examples:

```
SELECT id, a IN (SELECT /*+ SUBQUERY(MATERIALIZATION) */ a FROM t1) FROM t2;
SELECT * FROM t2 WHERE t2.a IN (SELECT /*+ SUBQUERY(INTOEXISTS) */ a FROM t1);
```

For semijoin and `SUBQUERY` hints, a leading `@query_block_name` specifies the query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

If a hint comment contains multiple subquery hints, the first is used. If there are other following hints of that type, they produce a warning. Following hints of other types are silently ignored.

Statement Execution Time Optimizer Hints

The `MAX_EXECUTION_TIME` hint is permitted only for `SELECT` statements. It places a limit *N* (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it:

```
MAX_EXECUTION_TIME(N)
```

Example with a timeout of 1 second (1000 milliseconds):

```
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM t1 INNER JOIN t2 WHERE ...
```

The `MAX_EXECUTION_TIME(N)` hint sets a statement execution timeout of *N* milliseconds. If this option is absent or *N* is 0, the statement timeout established by the `max_execution_time` system variable applies.

The `MAX_EXECUTION_TIME` hint is applicable as follows:

- For statements with multiple `SELECT` keywords, such as unions or statements with subqueries, `MAX_EXECUTION_TIME` applies to the entire statement and must appear after the first `SELECT`.
- It applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- It does not apply to `SELECT` statements in stored programs and is ignored.

Variable-Setting Hint Syntax

The `SET_VAR` hint sets the session value of a system variable temporarily (for the duration of a single statement). Examples:

```
SELECT /*+ SET_VAR(sort_buffer_size = 16M) */ name FROM people ORDER BY name;
INSERT /*+ SET_VAR(foreign_key_checks=OFF) */ INTO t2 VALUES(2);
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=off') */ 1;
```

Syntax of the `SET_VAR` hint:

```
SET_VAR(var_name = value)
```

var_name names a system variable that has a session value (although not all such variables can be named, as explained later). *value* is the value to assign to the variable; the value must be a scalar.

`SET_VAR` makes a temporary variable change, as demonstrated by these statements:

```
mysql> SELECT @@unique_checks;
+-----+
| @@unique_checks |
+-----+
| 1 |
+-----+
mysql> SELECT /*+ SET_VAR(unique_checks=OFF) */ @@unique_checks;
+-----+
| @@unique_checks |
+-----+
| 0 |
+-----+
mysql> SELECT @@unique_checks;
+-----+
| @@unique_checks |
+-----+
| 1 |
+-----+
```

With `SET_VAR`, there is no need to save and restore the variable value. This enables you to replace multiple statements by a single statement. Consider this sequence of statements:

```
SET @saved_val = @@SESSION.var_name;
SET @@SESSION.var_name = value;
SELECT ...
SET @@SESSION.var_name = @saved_val;
```

The sequence can be replaced by this single statement:

```
SELECT /*+ SET_VAR(var_name = value) ...
```

Standalone `SET` statements permit any of these syntaxes for naming session variables:

```
SET SESSION var_name = value;
SET @@SESSION.var_name = value;
SET @@.var_name = value;
```

Because the `SET_VAR` hint applies only to session variables, session scope is implicit, and `SESSION`, `@@SESSION.`, and `@@` are neither needed nor permitted. Including explicit session-indicator syntax results in the `SET_VAR` hint being ignored with a warning.

Not all session variables are permitted for use with `SET_VAR`. Individual system variable descriptions indicate whether each variable is hintable; see [Section 5.1.8, “Server System Variables”](#). You can also check a system variable at runtime by attempting to use it with `SET_VAR`. If the variable is not hintable, a warning occurs:

```
mysql> SELECT /*+ SET_VAR(collation_server = 'utf8') */ 1;
+----+
| 1 |
+----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 4537
Message: Variable 'collation_server' cannot be set using SET_VAR hint.
```

`SET_VAR` syntax permits setting only a single variable, but multiple hints can be given to set multiple variables:

```
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=off')
        SET_VAR(max_heap_table_size = 1G) */ 1;
```

If several hints with the same variable name appear in the same statement, the first one is applied and the others are ignored with a warning:

```
SELECT /*+ SET_VAR(max_heap_table_size = 1G)
        SET_VAR(max_heap_table_size = 3G) */ 1;
```

In this case, the second hint is ignored with a warning that it is conflicting.

A `SET_VAR` hint is ignored with a warning if no system variable has the specified name or the variable value is incorrect:

```
SELECT /*+ SET_VAR(max_size = 1G) */ 1;
SELECT /*+ SET_VAR(optimizer_switch = 'mrr_cost_based=yes') */ 1;
```

For the first statement, there is no `max_size` variable. For the second statement, `mrr_cost_flag` takes values of `on` or `off`, so attempting to set it to `yes` is incorrect. In each case, the hint is ignored with a warning.

The `SET_VAR` hint is permitted only at the statement level. If used in a subquery, the hint is ignored with a warning.

Replicas ignore `SET_VAR` hints in replicated statements to avoid the potential for security issues.

Resource Group Hint Syntax

The `RESOURCE_GROUP` optimizer hint is used for resource group management (see [Section 5.1.15, “Resource Groups”](#)). This hint assigns the thread that executes a statement to the named resource group temporarily (for the duration of the statement). It requires the `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege.

Examples:

```
SELECT /*+ RESOURCE_GROUP(USR_default) */ name FROM people ORDER BY name;
INSERT /*+ RESOURCE_GROUP(Batch) */ INTO t2 VALUES(2);
```

Syntax of the `RESOURCE_GROUP` hint:

```
RESOURCE_GROUP(group_name)
```

group_name indicates the resource group to which the thread should be assigned for the duration of statement execution. If the group is nonexistent, a warning occurs and the hint is ignored.

The `RESOURCE_GROUP` hint must appear after the initial statement keyword (`SELECT`, `INSERT`, `REPLACE`, `UPDATE`, or `DELETE`).

An alternative to `RESOURCE_GROUP` is the `SET RESOURCE GROUP` statement, which nontemporarily assigns threads to a resource group. See [Section 13.7.2.4, “SET RESOURCE GROUP Statement”](#).

Optimizer Hints for Naming Query Blocks

Table-level, index-level, and subquery optimizer hints permit specific query blocks to be named as part of their argument syntax. To create these names, use the `QB_NAME` hint, which assigns a name to the query block in which it occurs:

```
QB_NAME(name)
```

`QB_NAME` hints can be used to make explicit in a clear way which query blocks other hints apply to. They also permit all non-query block name hints to be specified within a single hint comment for easier understanding of complex statements. Consider the following statement:

```
SELECT ...
FROM (SELECT ...
FROM (SELECT ... FROM ...)) ...
```

`QB_NAME` hints assign names to query blocks in the statement:

```
SELECT /*+ QB_NAME(qb1) */ ...
FROM (SELECT /*+ QB_NAME(qb2) */ ...
FROM (SELECT /*+ QB_NAME(qb3) */ ... FROM ...)) ...
```

Then other hints can use those names to refer to the appropriate query blocks:

```
SELECT /*+ QB_NAME(qb1) MRR(@qb1 t1) BKA(@qb2) NO_MRR(@qb3 t1 idx1, idx2) */ ...
FROM (SELECT /*+ QB_NAME(qb2) */ ...
FROM (SELECT /*+ QB_NAME(qb3) */ ... FROM ...)) ...
```

The resulting effect is as follows:

- `MRR(@qb1 t1)` applies to table `t1` in query block `qb1`.
- `BKA(@qb2)` applies to query block `qb2`.
- `NO_MRR(@qb3 t1 idx1, idx2)` applies to indexes `idx1` and `idx2` in table `t1` in query block `qb3`.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see [Section 9.2, “Schema Object Names”](#)). For example, a query block name that contains spaces must be quoted, which can be done using backticks:

```
SELECT /*+ BKA(@`my hint name`) */ ...
FROM (SELECT /*+ QB_NAME(`my hint name`) */ ...) ...
```

If the `ANSI_QUOTES` SQL mode is enabled, it is also possible to quote query block names within double quotation marks:

```
SELECT /*+ BKA(@"my hint name") */ ...
FROM (SELECT /*+ QB_NAME("my hint name") */ ...) ...
```

8.9.4 Index Hints

Index hints give the optimizer information about how to choose indexes during query processing. Index hints, described here, differ from optimizer hints, described in [Section 8.9.3, “Optimizer Hints”](#). Index and optimizer hints may be used separately or together.

Index hints apply only to `SELECT` and `UPDATE` statements.

Index hints are specified following a table name. (For the general syntax for specifying tables in a `SELECT` statement, see [Section 13.2.10.2, “JOIN Clause”](#).) The syntax for referring to an individual table, including index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]

index_hint_list:
    index_hint [index_hint] ...

index_hint:
    USE {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
    | {IGNORE|FORCE} {INDEX|KEY}
      [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
    index_name [, index_name] ...
```

The `USE INDEX (index_list)` hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` tells MySQL to not use some particular index or indexes. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

The `FORCE INDEX` hint acts like `USE INDEX (index_list)`, with the addition that a table scan is assumed to be very expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

Note

As of MySQL 8.0.20, the server supports the index-level optimizer hints `JOIN_INDEX`, `GROUP_INDEX`, `ORDER_INDEX`, and `INDEX`, which are equivalent to and intended to supersede `FORCE INDEX` index hints, as well as the `NO_JOIN_INDEX`, `NO_GROUP_INDEX`, `NO_ORDER_INDEX`, and `NO_INDEX` optimizer hints, which are equivalent to and intended to supersede `IGNORE INDEX` index hints. Thus, you should expect `USE INDEX`, `FORCE INDEX`, and `IGNORE INDEX` to be deprecated in a future release of MySQL, and at some time thereafter to be removed altogether. For more information, see [Index-Level Optimizer Hints](#).

Each hint requires index names, not column names. To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA.STATISTICS` table.

An `index_name` value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Examples:

```
SELECT * FROM table1 USE INDEX (col1_index,col2_index)
  WHERE col1=1 AND col2=2 AND col3=3;

SELECT * FROM table1 IGNORE INDEX (col3_index)
  WHERE col1=1 AND col2=2 AND col3=3;
```

The syntax for index hints has the following characteristics:

- It is syntactically valid to omit `index_list` for `USE INDEX`, which means “use no indexes.” Omitting `index_list` for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.
- You can specify the scope of an index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over optimizer selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use `FOR JOIN`. To influence index usage for sorting or grouping rows, use `FOR ORDER BY` or `FOR GROUP BY`.
- You can specify multiple index hints:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not an error to name the same index in several hints (even within the same hint):

```
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix `USE INDEX` and `FORCE INDEX` for the same table:

```
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

If an index hint includes no `FOR` clause, the scope of the hint is to apply to all parts of the statement. For example, this hint:

```
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

In MySQL 5.0, hint scope with no `FOR` clause was to apply only to row retrieval. To cause the server to use this older behavior when no `FOR` clause is present, enable the `old` system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the source and replicas might lead to replication errors.

When index hints are processed, they are collected in a single list by type (`USE`, `FORCE`, `IGNORE`) and by scope (`FOR JOIN`, `FOR ORDER BY`, `FOR GROUP BY`). For example:

```
SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. `{USE|FORCE} INDEX` is applied if present. (If not, the optimizer-determined set of indexes is used.)
2. `IGNORE INDEX` is applied over the result of the previous step. For example, the following two queries are equivalent:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);

SELECT * FROM t1 USE INDEX (i1);
```

For `FULLTEXT` searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, `IGNORE INDEX(i1)` is ignored with no warning and the index is still used.
- For boolean mode searches, index hints with `FOR ORDER BY` or `FOR GROUP BY` are silently ignored. Index hints with `FOR JOIN` or no `FOR` modifier are honored. In contrast to how hints apply for non-`FULLTEXT` searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-`FULLTEXT` index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
  USE INDEX (index1)
  IGNORE INDEX (index1) FOR ORDER BY
  IGNORE INDEX (index1) FOR GROUP BY
  WHERE ... IN BOOLEAN MODE ... ;

SELECT * FROM t
  USE INDEX (index1)
  WHERE ... IN BOOLEAN MODE ... ;
```

8.9.5 The Optimizer Cost Model

To generate execution plans, the optimizer uses a cost model that is based on estimates of the cost of various operations that occur during query execution. The optimizer has a set of compiled-in default “cost constants” available to it to make decisions regarding execution plans.

The optimizer also has a database of cost estimates to use during execution plan construction. These estimates are stored in the `server_cost` and `engine_cost` tables in the `mysql` system database and are configurable at any time. The intent of these tables is to make it possible to easily adjust the cost estimates that the optimizer uses when it attempts to arrive at query execution plans.

- [Cost Model General Operation](#)
- [The Cost Model Database](#)

- [Making Changes to the Cost Model Database](#)

Cost Model General Operation

The configurable optimizer cost model works like this:

- The server reads the cost model tables into memory at startup and uses the in-memory values at runtime. Any non-`NULL` cost estimate specified in the tables takes precedence over the corresponding compiled-in default cost constant. Any `NULL` estimate indicates to the optimizer to use the compiled-in default.
- At runtime, the server may reread the cost tables. This occurs when a storage engine is dynamically loaded or when a `FLUSH OPTIMIZER_COSTS` statement is executed.
- Cost tables enable server administrators to easily adjust cost estimates by changing entries in the tables. It is also easy to revert to a default by setting an entry's cost to `NULL`. The optimizer uses the in-memory cost values, so changes to the tables should be followed by `FLUSH OPTIMIZER_COSTS` to take effect.
- The in-memory cost estimates that are current when a client session begins apply throughout that session until it ends. In particular, if the server rereads the cost tables, any changed estimates apply only to subsequently started sessions. Existing sessions are unaffected.
- Cost tables are specific to a given server instance. The server does not replicate cost table changes to replicas.

The Cost Model Database

The optimizer cost model database consists of two tables in the `mysql` system database that contain cost estimate information for operations that occur during query execution:

- `server_cost`: Optimizer cost estimates for general server operations
- `engine_cost`: Optimizer cost estimates for operations specific to particular storage engines

The `server_cost` table contains these columns:

- `cost_name`

The name of a cost estimate used in the cost model. The name is not case-sensitive. If the server does not recognize the cost name when it reads this table, it writes a warning to the error log.

- `cost_value`

The cost estimate value. If the value is non-`NULL`, the server uses it as the cost. Otherwise, it uses the default estimate (the compiled-in value). DBAs can change a cost estimate by updating this column. If the server finds that the cost value is invalid (nonpositive) when it reads this table, it writes a warning to the error log.

To override a default cost estimate (for an entry that specifies `NULL`), set the cost to a non-`NULL` value. To revert to the default, set the value to `NULL`. Then execute `FLUSH OPTIMIZER_COSTS` to tell the server to reread the cost tables.

- `last_update`

The time of the last row update.

- `comment`

A descriptive comment associated with the cost estimate. DBAs can use this column to provide information about why a cost estimate row stores a particular value.

- `default_value`

The default (compiled-in) value for the cost estimate. This column is a read-only generated column that retains its value even if the associated cost estimate is changed. For rows added to the table at runtime, the value of this column is `NULL`.

The primary key for the `server_cost` table is the `cost_name` column, so it is not possible to create multiple entries for any cost estimate.

The server recognizes these `cost_name` values for the `server_cost` table:

- `disk temptable_create_cost`, `disk temptable_row_cost`

The cost estimates for internally created temporary tables stored in a disk-based storage engine (either `InnoDB` or `MyISAM`). Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

The larger default values for these disk parameters compared to the default values for the corresponding memory parameters (`memory temptable_create_cost`, `memory temptable_row_cost`) reflects the greater cost of processing disk-based tables.

- `key_compare_cost`

The cost of comparing record keys. Increasing this value causes a query plan that compares many keys to become more expensive. For example, a query plan that performs a `filesort` becomes relatively more expensive compared to a query plan that avoids sorting by using an index.

- `memory temptable_create_cost`, `memory temptable_row_cost`

The cost estimates for internally created temporary tables stored in the `MEMORY` storage engine. Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

The smaller default values for these memory parameters compared to the default values for the corresponding disk parameters (`disk temptable_create_cost`, `disk temptable_row_cost`) reflects the lesser cost of processing memory-based tables.

- `row_evaluate_cost`

The cost of evaluating record conditions. Increasing this value causes a query plan that examines many rows to become more expensive compared to a query plan that examines fewer rows. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer rows.

The `engine_cost` table contains these columns:

- `engine_name`

The name of the storage engine to which this cost estimate applies. The name is not case-sensitive. If the value is `default`, it applies to all storage engines that have no named entry of their own. If the server does not recognize the engine name when it reads this table, it writes a warning to the error log.

- `device_type`

The device type to which this cost estimate applies. The column is intended for specifying different cost estimates for different storage device types, such as hard disk drives versus solid state drives. Currently, this information is not used and 0 is the only permitted value.

- `cost_name`

Same as in the `server_cost` table.

- `cost_value`

Same as in the `server_cost` table.

- `last_update`

Same as in the `server_cost` table.

- `comment`

Same as in the `server_cost` table.

- `default_value`

The default (compiled-in) value for the cost estimate. This column is a read-only generated column that retains its value even if the associated cost estimate is changed. For rows added to the table at runtime, the value of this column is `NULL`, with the exception that if the row has the same `cost_name` value as one of the original rows, the `default_value` column will have the same value as that row.

The primary key for the `engine_cost` table is a tuple comprising the (`cost_name`, `engine_name`, `device_type`) columns, so it is not possible to create multiple entries for any combination of values in those columns.

The server recognizes these `cost_name` values for the `engine_cost` table:

- `io_block_read_cost`

The cost of reading an index or data block from disk. Increasing this value causes a query plan that reads many disk blocks to become more expensive compared to a query plan that reads fewer disk blocks. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer blocks.

- `memory_block_read_cost`

Similar to `io_block_read_cost`, but represents the cost of reading an index or data block from an in-memory database buffer.

If the `io_block_read_cost` and `memory_block_read_cost` values differ, the execution plan may change between two runs of the same query. Suppose that the cost for memory access is less than the cost for disk access. In that case, at server startup before data has been read into the buffer pool, you may get a different plan than after the query has been run because then the data will be in memory.

Making Changes to the Cost Model Database

For DBAs who wish to change the cost model parameters from their defaults, try doubling or halving the value and measuring the effect.

Changes to the `io_block_read_cost` and `memory_block_read_cost` parameters are most likely to yield worthwhile results. These parameter values enable cost models for data access methods to take into account the costs of reading information from different sources; that is, the cost of reading information from disk versus reading information already in a memory buffer. For example, all other things being equal, setting `io_block_read_cost` to a value larger than `memory_block_read_cost` causes the optimizer to prefer query plans that read information already held in memory to plans that must read from disk.

This example shows how to change the default value for `io_block_read_cost`:

```
UPDATE mysql.engine_cost
```

```
SET cost_value = 2.0
WHERE cost_name = 'io_block_read_cost';
FLUSH OPTIMIZER_COSTS;
```

This example shows how to change the value of `io_block_read_cost` only for the `InnoDB` storage engine:

```
INSERT INTO mysql.engine_cost
VALUES ('InnoDB', 0, 'io_block_read_cost', 3.0,
CURRENT_TIMESTAMP, 'Using a slower disk for InnoDB');
FLUSH OPTIMIZER_COSTS;
```

8.9.6 Optimizer Statistics

The `column_statistics` data dictionary table stores histogram statistics about column values, for use by the optimizer in constructing query execution plans. To perform histogram management, use the `ANALYZE TABLE` statement.

The `column_statistics` table has these characteristics:

- The table contains statistics for columns of all data types except geometry types (spatial data) and `JSON`.
- The table is persistent so that column statistics need not be created each time the server starts.
- The server performs updates to the table; users do not.

The `column_statistics` table is not directly accessible by users because it is part of the data dictionary. Histogram information is available using `INFORMATION_SCHEMA.COLUMN_STATISTICS`, which is implemented as a view on the data dictionary table. `COLUMN_STATISTICS` has these columns:

- `SCHEMA_NAME`, `TABLE_NAME`, `COLUMN_NAME`: The names of the schema, table, and column for which the statistics apply.
- `HISTOGRAM`: A `JSON` value describing the column statistics, stored as a histogram.

Column histograms contain buckets for parts of the range of values stored in the column. Histograms are `JSON` objects to permit flexibility in the representation of column statistics. Here is a sample histogram object:

```
{
  "buckets": [
    [
      1,
      0.3333333333333333
    ],
    [
      2,
      0.6666666666666666
    ],
    [
      3,
      1
    ]
  ],
  "null-values": 0,
  "last-updated": "2017-03-24 13:32:40.000000",
  "sampling-rate": 1,
  "histogram-type": "singleton",
  "number-of-buckets-specified": 128,
  "data-type": "int",
  "collation-id": 8
}
```

Histogram objects have these keys:

- **buckets**: The histogram buckets. Bucket structure depends on the histogram type.

For **singleton** histograms, buckets contain two values:

- Value 1: The value for the bucket. The type depends on the column data type.
- Value 2: A double representing the cumulative frequency for the value. For example, .25 and .75 indicate that 25% and 75% of the values in the column are less than or equal to the bucket value.

For **equi-height** histograms, buckets contain four values:

- Values 1, 2: The lower and upper inclusive values for the bucket. The type depends on the column data type.
- Value 3: A double representing the cumulative frequency for the value. For example, .25 and .75 indicate that 25% and 75% of the values in the column are less than or equal to the bucket upper value.
- Value 4: The number of distinct values in the range from the bucket lower value to its upper value.
- **null-values**: A number between 0.0 and 1.0 indicating the fraction of column values that are SQL **NULL** values. If 0, the column contains no **NULL** values.
- **last-updated**: When the histogram was generated, as a UTC value in **YYYY-MM-DD hh:mm:ss.uuuuuu** format.
- **sampling-rate**: A number between 0.0 and 1.0 indicating the fraction of data that was sampled to create the histogram. A value of 1 means that all of the data was read (no sampling).
- **histogram-type**: The histogram type:
 - **singleton**: One bucket represents one single value in the column. This histogram type is created when the number of distinct values in the column is less than or equal to the number of buckets specified in the **ANALYZE TABLE** statement that generated the histogram.
 - **equi-height**: One bucket represents a range of values. This histogram type is created when the number of distinct values in the column is greater than the number of buckets specified in the **ANALYZE TABLE** statement that generated the histogram.
- **number-of-buckets-specified**: The number of buckets specified in the **ANALYZE TABLE** statement that generated the histogram.
- **data-type**: The type of data this histogram contains. This is needed when reading and parsing histograms from persistent storage into memory. The value is one of **int**, **uint** (unsigned integer), **double**, **decimal**, **datetime**, or **string** (includes character and binary strings).
- **collation-id**: The collation ID for the histogram data. It is mostly meaningful when the **data-type** value is **string**. Values correspond to **ID** column values in the **INFORMATION_SCHEMA.COLLATIONS** table.

To extract particular values from the histogram objects, you can use **JSON** operations. For example:

```
mysql> SELECT
    TABLE_NAME, COLUMN_NAME,
    HISTOGRAM->>'$.data-type' AS 'data-type',
    JSON_LENGTH(HISTOGRAM->>'$.buckets') AS 'bucket-count'
    FROM INFORMATION_SCHEMA.COLUMN_STATISTICS;
```

TABLE_NAME	COLUMN_NAME	data-type	bucket-count
country	Population	int	226
city	Population	int	1024
countrylanguage	Language	string	457

The optimizer uses histogram statistics, if applicable, for columns of any data type for which statistics are collected. The optimizer applies histogram statistics to determine row estimates based on the selectivity (filtering effect) of column value comparisons against constant values. Predicates of these forms qualify for histogram use:

```
col_name = constant
col_name <> constant
col_name != constant
col_name > constant
col_name < constant
col_name >= constant
col_name <= constant
col_name IS NULL
col_name IS NOT NULL
col_name BETWEEN constant AND constant
col_name NOT BETWEEN constant AND constant
col_name IN (constant[, constant] ...)
col_name NOT IN (constant[, constant] ...)
```

For example, these statements contain predicates that qualify for histogram use:

```
SELECT * FROM orders WHERE amount BETWEEN 100.0 AND 300.0;
SELECT * FROM tbl WHERE col1 = 15 AND col2 > 100;
```

The requirement for comparison against a constant value includes functions that are constant, such as `ABS()` and `FLOOR()`:

```
SELECT * FROM tbl WHERE col1 < ABS(-34);
```

Histogram statistics are useful primarily for nonindexed columns. Adding an index to a column for which histogram statistics are applicable might also help the optimizer make row estimates. The tradeoffs are:

- An index must be updated when table data is modified.
- A histogram is created or updated only on demand, so it adds no overhead when table data is modified. On the other hand, the statistics become progressively more out of date when table modifications occur, until the next time they are updated.

The optimizer prefers range optimizer row estimates to those obtained from histogram statistics. If the optimizer determines that the range optimizer applies, it does not use histogram statistics.

For columns that are indexed, row estimates can be obtained for equality comparisons using index dives (see [Section 8.2.1.2, “Range Optimization”](#)). In this case, histogram statistics are not necessarily useful because index dives can yield better estimates.

In some cases, use of histogram statistics may not improve query execution (for example, if the statistics are out of date). To check whether this is the case, use `ANALYZE TABLE` to regenerate the histogram statistics, then run the query again.

Alternatively, to disable histogram statistics, use `ANALYZE TABLE` to drop them. A different method of disabling histogram statistics is to turn off the `condition_fanout_filter` flag of the `optimizer_switch` system variable (although this may disable other optimizations as well):

```
SET optimizer_switch='condition_fanout_filter=off';
```

If histogram statistics are used, the resulting effect is visible using `EXPLAIN`. Consider the following query, where no index is available for column `col1`:

```
SELECT * FROM t1 WHERE col1 < 24;
```

If histogram statistics indicate that 57% of the rows in `t1` satisfy the `col1 < 24` predicate, filtering can occur even in the absence of an index, and `EXPLAIN` shows 57.00 in the `filtered` column.

8.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

8.10.1 InnoDB Buffer Pool Optimization

[InnoDB](#) maintains a storage area called the [buffer pool](#) for caching data and indexes in memory. Knowing how the [InnoDB](#) buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.

For an explanation of the inner workings of the [InnoDB](#) buffer pool, an overview of its LRU replacement algorithm, and general configuration information, see [Section 15.5.1, “Buffer Pool”](#).

For additional [InnoDB](#) buffer pool configuration and tuning information, see these sections:

- [Section 15.8.3.4, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#)
- [Section 15.8.3.5, “Configuring Buffer Pool Flushing”](#)
- [Section 15.8.3.3, “Making the Buffer Pool Scan Resistant”](#)
- [Section 15.8.3.2, “Configuring Multiple Buffer Pool Instances”](#)
- [Section 15.8.3.6, “Saving and Restoring the Buffer Pool State”](#)
- [Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”](#)

8.10.2 The MyISAM Key Cache

To minimize disk I/O, the [MyISAM](#) storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the [MyISAM](#) key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the [key_buffer_size](#) system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the [key_buffer_size](#) value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the [MyISAM](#) index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk. Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an *LRU (Least Recently Used)* strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (*LRU chain*) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The [InnoDB](#) storage engine also uses an LRU algorithm, to manage its buffer pool. See [Section 15.5.1, “Buffer Pool”](#).

8.10.2.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

8.10.2.2 Multiple Key Caches

Note

As of MySQL 8.0, the compound-part structured-variable syntax discussed here for referring to multiple [MyISAM](#) key caches is deprecated.

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given [MyISAM](#) table. By default, all [MyISAM](#) table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the [CACHE INDEX](#) statement (see [Section 13.7.8.2, “CACHE INDEX Statement”](#)). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

Table	Op	Msg_type	Msg_text
test.t1	assign_to_keycache	status	OK
test.t2	assign_to_keycache	status	OK
test.t3	assign_to_keycache	status	OK

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a `SET GLOBAL` parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

You cannot destroy the default key cache. Any attempt to do this is ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| key_buffer_size | 8384512 |
+-----+-----+
```

Key cache variables are structured system variables that have a name and components. For `keycache1.key_buffer_size`, `keycache1` is the cache variable name and `key_buffer_size` is the cache component. See [Section 5.1.9.5, “Structured System Variables”](#), for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The `CACHE INDEX` statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init_file` system variable that names a file containing `CACHE INDEX` statements to be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
```

```
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysql_init.sql
```

The statements in `mysql_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

8.10.2.3 Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the *midpoint insertion strategy*.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing N blocks, the block at the beginning of the hot sublist not accessed within the last $N * \text{key_cache_age_threshold} / 100$ hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

8.10.2.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op   | Msg_type | Msg_text |
+-----+-----+-----+-----+
```

test.t1	preload_keys	status	OK
test.t2	preload_keys	status	OK

The **IGNORE LEAVES** modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a **CACHE INDEX** statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

8.10.2.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of **MyISAM** tables, use the `--myisam-block-size` option at server startup.

8.10.2.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

8.10.3 Caching of Prepared Statements and Stored Programs

For certain statements that a client might execute multiple times during a session, the server converts the statement to an internal structure and caches that structure to be used during execution. Caching enables the server to perform more efficiently because it avoids the overhead of reconverting the statement should it be needed again during the session. Conversion and caching occurs for these statements:

- Prepared statements, both those processed at the SQL level (using the **PREPARE** statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function). The `max_prepared_stmt_count` system variable controls the total number of statements the server caches. (The sum of the number of prepared statements across all sessions.)
- Stored programs (stored procedures and functions, triggers, and events). In this case, the server converts and caches the entire program body. The `stored_program_cache` system variable indicates the approximate number of stored programs the server caches per session.

The server maintains caches for prepared statements and stored programs on a per-session basis. Statements cached for one session are not accessible to other sessions. When a session ends, the server discards any statements cached for it.

When the server uses a cached internal statement structure, it must take care that the structure does not go out of date. Metadata changes can occur for an object used by the statement, causing a mismatch between the current object definition and the definition as represented in the internal statement structure. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Table content changes (for example, with [INSERT](#) or [UPDATE](#)) do not change metadata, nor do [SELECT](#) statements.

Here is an illustration of the problem. Suppose that a client prepares this statement:

```
PREPARE s1 FROM 'SELECT * FROM t1';
```

The [SELECT *](#) expands in the internal structure to the list of columns in the table. If the set of columns in the table is modified with [ALTER TABLE](#), the prepared statement goes out of date. If the server does not detect this change the next time the client executes [s1](#), the prepared statement will return incorrect results.

To avoid problems caused by metadata changes to tables or views referred to by the prepared statement, the server detects these changes and automatically reprepares the statement when it is next executed. That is, the server reparses the statement and rebuilds the internal structure. Reparsing also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to [FLUSH TABLES](#).

Similarly, if changes occur to objects used by a stored program, the server reparses affected statements within the program.

The server also detects metadata changes for objects in expressions. These might be used in statements specific to stored programs, such as [DECLARE CURSOR](#) or flow-control statements such as [IF](#), [CASE](#), and [RETURN](#).

To avoid reparsing entire stored programs, the server reparses affected statements or expressions within a program only as needed. Examples:

- Suppose that metadata for a table or view is changed. Reparsing occurs for a [SELECT *](#) within the program that accesses the table or view, but not for a [SELECT *](#) that does not access the table or view.
- When a statement is affected, the server reparses it only partially if possible. Consider this [CASE](#) statement:

```
CASE case_expr
  WHEN when_expr1 ...
  WHEN when_expr2 ...
  WHEN when_expr3 ...
  ...
END CASE
```

If a metadata change affects only [WHEN when_expr3](#), that expression is reparsed. [case_expr](#) and the other [WHEN](#) expressions are not reparsed.

Reparsing uses the default database and SQL mode that were in effect for the original conversion to internal form.

The server attempts reparsing up to three times. An error occurs if all attempts fail.

Reparsing is automatic, but to the extent that it occurs, diminishes prepared statement and stored program performance.

For prepared statements, the [Com_stmt_reprepare](#) status variable tracks the number of reparsings.

8.11 Optimizing Locking Operations

MySQL manages contention for table contents using [locking](#):

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See [Section 8.11.1](#), “Internal Locking Methods”.
- External locking occurs when the server and other programs lock [MyISAM](#) table files to coordinate among themselves which program can access the tables at which time. See [Section 8.11.5](#), “External Locking”.

8.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see [Section 8.11.5](#), “External Locking”.

- [Row-Level Locking](#)
- [Table-Level Locking](#)
- [Choosing the Type of Locking](#)

Row-Level Locking

MySQL uses [row-level locking](#) for [InnoDB](#) tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid [deadlocks](#) when performing multiple concurrent write operations on a single [InnoDB](#) table, acquire necessary locks at the start of the transaction by issuing a `SELECT ... FOR UPDATE` statement for each group of rows expected to be modified, even if the data change statements come later in the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because [InnoDB](#) automatically [detects](#) deadlock conditions by default and rolls back one of the affected transactions.

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows.
- Fewer changes for rollbacks.
- Possible to lock a single row for a long time.

Table-Level Locking

MySQL uses [table-level locking](#) for [MyISAM](#), [MEMORY](#), and [MERGE](#) tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.

These storage engines avoid [deadlocks](#) by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current data change statement finishes.

Advantages of table-level locking:

- Relatively little memory required (row locking requires memory per row or group of rows locked)
- Fast when used on a large part of the table because only a single lock is involved.
- Fast if you often do `GROUP BY` operations on a large part of the data or must scan the entire table frequently.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy `SELECT` activity for the table. However, if there are many updates for a table, `SELECT` statements wait until there are no more updates.

For information on altering the priority of reads and writes, see [Section 8.11.2, “Table Locking Issues”](#).

You can analyze the table lock contention on your system by checking the `Table_locks_immediate` and `Table_locks_waited` status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Table_locks_immediate | 1151552 |
| Table_locks_waited    | 15324  |
+-----+-----+
```

The Performance Schema lock tables also provide locking information. See [Section 26.12.13, “Performance Schema Lock Tables”](#).

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent `INSERT` and `SELECT` statements for a `MyISAM` table without locks. That is, you can insert rows into a `MyISAM` table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. To control this behavior, use the `concurrent_insert` system variable. See [Section 8.11.3, “Concurrent Inserts”](#).

If you acquire a table lock explicitly with `LOCK TABLES`, you can request a `READ LOCAL` lock rather than a `READ` lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many `INSERT` and `SELECT` operations on a table `t1` when concurrent inserts are not possible, you can insert rows into a temporary table `temp_t1` and update the real table with the rows from the temporary table:

```
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
```

```
mysql> UNLOCK TABLES;
```

Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads.
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

```
UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;
DELETE FROM tbl_name WHERE unique_key_col=key_value;
```

- **SELECT** combined with concurrent **INSERT** statements, and very few **UPDATE** or **DELETE** statements.
- Many scans or **GROUP BY** operations on the entire table without any writers.

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”
- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.
- Instead of using row-level locks, you can employ application-level locks, such as those provided by **GET_LOCK()** and **RELEASE_LOCK()** in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See [Section 12.15, “Locking Functions”](#).

8.11.2 Table Locking Issues

InnoDB tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this storage engine, avoid using the **LOCK TABLES** statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the **InnoDB** storage engine is the default in MySQL.

MySQL uses table locking (instead of page, row, or column locking) for all storage engines except **InnoDB**. The locking operations themselves do not have much overhead. But because only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

- [Performance Considerations Favoring InnoDB](#)
- [Workarounds for Locking Performance Issues](#)

Performance Considerations Favoring InnoDB

When choosing whether to create a table using **InnoDB** or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to

finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.

- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.
- A `SELECT` statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue `SELECT` statements will queue up behind it, reducing concurrency even for read-only sessions.

Workarounds for Locking Performance Issues

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the `InnoDB` storage engine, either using `CREATE TABLE ... ENGINE=INNODB` during setup, or using `ALTER TABLE ... ENGINE=INNODB` for an existing table. See [Chapter 15, The InnoDB Storage Engine](#) for more details about this storage engine.
- Optimize `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.
- Start `mysqld` with `--low-priority-updates`. For storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`), this gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not wait for the first `SELECT` to finish.
- To specify that all updates issued in a specific connection should be done with low priority, set the `low_priority_updates` server system variable equal to 1.
- To give a specific `INSERT`, `UPDATE`, or `DELETE` statement lower priority, use the `LOW_PRIORITY` attribute.
- To give a specific `SELECT` statement higher priority, use the `HIGH_PRIORITY` attribute. See [Section 13.2.10, “SELECT Statement”](#).
- Start `mysqld` with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of inserts to the table occur. This permits `READ` locks after a certain number of `WRITE` locks.
- If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See [Section 13.2.2, “DELETE Statement”](#).
- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See [Section 13.2.10, “SELECT Statement”](#).
- Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.
- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

8.11.3 Concurrent Inserts

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If `concurrent_insert` is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` system variable.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See [Section 5.4.4, “The Binary Log”](#). In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA`, if you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

8.11.4 Metadata Locking

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, scheduled events), tablespaces, user locks acquired with the `GET_LOCK()` function (see [Section 12.15, “Locking Functions”](#)), and locks acquired with the locking service described in [Section 5.6.8.1, “The Locking Service”](#).

The Performance Schema `metadata_locks` table exposes metadata lock information, which can be useful for seeing which sessions hold locks, are blocked waiting for locks, and so forth. For details, see [Section 26.12.13.3, “The metadata_locks Table”](#).

Metadata locking does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition cache, and its mutexes and locks differ from the `LOCK_open` mutex. The following discussion provides some information about how metadata locking works.

- [Metadata Lock Acquisition](#)
- [Metadata Lock Release](#)

Metadata Lock Acquisition

If there are multiple waiters for a given lock, the highest-priority lock request is satisfied first, with an exception related to the `max_write_lock_count` system variable. Write lock requests have higher priority than read lock requests. However, if `max_write_lock_count` is set to some low value (say, 10), read lock requests may be preferred over pending write lock requests if the read lock requests have already been passed over in favor of 10 write lock requests. Normally this behavior does not occur because `max_write_lock_count` by default has a very large value.

Statements acquire metadata locks one by one, not simultaneously, and perform deadlock detection in the process.

DML statements normally acquire locks in the order in which tables are mentioned in the statement.

DDL statements, `LOCK TABLES`, and other similar statements try to reduce the number of possible deadlocks between concurrent DDL statements by acquiring locks on explicitly named tables in name order. Locks might be acquired in a different order for implicitly used tables (such as tables in foreign key relationships that also must be locked).

For example, `RENAME TABLE` is a DDL statement that acquires locks in name order:

- This `RENAME TABLE` statement renames `tbla` to something else, and renames `tblc` to `tbla`:

```
RENAME TABLE tbla TO tblb, tblc TO tbla;
```

The statement acquires metadata locks, in order, on `tbla`, `tblc`, and `tblb` (because `tblb` follows `tblc` in name order):

- This slightly different statement also renames `tbla` to something else, and renames `tblc` to `tbla`:

```
RENAME TABLE tbla TO tblb, tblc TO tbla;
```

In this case, the statement acquires metadata locks, in order, on `tbla`, `tblb`, and `tblc` (because `tblb` precedes `tblc` in name order):

Both statements acquire locks on `tbla` and `tblc`, in that order, but differ in whether the lock on the remaining table name is acquired before or after `tblc`.

Metadata lock acquisition order can make a difference in operation outcome when multiple transactions execute concurrently, as the following example illustrates.

Begin with two tables `x` and `x_new` that have identical structure. Three clients issue statements that involve these tables:

Client 1:

```
LOCK TABLE x WRITE, x_new WRITE;
```

The statement requests and acquires write locks in name order on `x` and `x_new`.

Client 2:

```
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

Client 3:

```
RENAME TABLE x TO x_old, x_new TO x;
```

The statement requests exclusive locks in name order on `x`, `x_new`, and `x_old`, but blocks waiting for the lock on `x`.

Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `x_new`. The exclusive lock request for `x` by Client 3 has higher priority than the write lock request by Client 2, so Client 3 acquires its lock on `x`, then also on `x_new` and `x_old`, performs the renaming, and releases its locks. Client 2 then acquires its lock on `x`, performs the insert, and releases its lock.

Lock acquisition order results in the `RENAME TABLE` executing before the `INSERT`. The `x` into which the insert occurs is the table that was named `x_new` when Client 2 issued the insert and was renamed to `x` by Client 3:

```
mysql> SELECT * FROM x;
+-----+
| i     |
```

```
+-----+
|      1      |
+-----+

mysql> SELECT * FROM x_old;
Empty set (0.01 sec)
```

Now begin instead with tables named `x` and `new_x` that have identical structure. Again, three clients issue statements that involve these tables:

Client 1:

```
LOCK TABLE x WRITE, new_x WRITE;
```

The statement requests and acquires write locks in name order on `new_x` and `x`.

Client 2:

```
INSERT INTO x VALUES(1);
```

The statement requests and blocks waiting for a write lock on `x`.

Client 3:

```
RENAME TABLE x TO old_x, new_x TO x;
```

The statement requests exclusive locks in name order on `new_x`, `old_x`, and `x`, but blocks waiting for the lock on `new_x`.

Client 1:

```
UNLOCK TABLES;
```

The statement releases the write locks on `x` and `new_x`. For `x`, the only pending request is by Client 2, so Client 2 acquires its lock, performs the insert, and releases the lock. For `new_x`, the only pending request is by Client 3, which is permitted to acquire that lock (and also the lock on `old_x`). The rename operation still blocks for the lock on `x` until the Client 2 insert finishes and releases its lock. Then Client 3 acquires the lock on `x`, performs the rename, and releases its lock.

In this case, lock acquisition order results in the `INSERT` executing before the `RENAME TABLE`. The `x` into which the insert occurs is the original `x`, now renamed to `old_x` by the rename operation:

```
mysql> SELECT * FROM x;
Empty set (0.01 sec)

mysql> SELECT * FROM old_x;
+-----+
| i      |
+-----+
|      1      |
+-----+
```

If order of lock acquisition in concurrent statements makes a difference to an application in operation outcome, as in the preceding example, you may be able to adjust the table names to affect the order of lock acquisition.

Metadata locks are extended, as necessary, to tables related by a foreign key constraint to prevent conflicting DML and DDL operations from executing concurrently on the related tables. When updating a parent table, a metadata lock is taken on the child table while updating foreign key metadata. Foreign key metadata is owned by the child table.

Metadata Lock Release

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted explicitly or implicitly started transaction in another session. The server achieves this by acquiring metadata locks on tables used

within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table `t` and nontransactional table `nt` as follows:

```
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

The server holds metadata locks on both `t` and `nt` until the transaction ends. If another session attempts a DDL or write lock operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:

```
DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
LOCK TABLE t ... WRITE;
```

The same behavior applies for The `LOCK TABLES ... READ`. That is, explicitly or implicitly started transactions that update any table (transactional or nontransactional) will block and be blocked by `LOCK TABLES ... READ` for that table.

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

As of MySQL 8.0.13, for XA transactions in `PREPARED` state, metadata locks are maintained across client disconnects and server restarts, until an `XA COMMIT` or `XA ROLLBACK` is executed.

8.11.5 External Locking

External locking is the use of file system locking to manage contention for `MyISAM` database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.
- If you use `myisamchk` to perform table maintenance operations on `MyISAM` tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `myisampack` to pack `MyISAM` tables.

If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such as checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `myisampack` to pack tables, you *must* always ensure that the `mysqld` server is not using the table. If you do not stop `mysqld`, at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is running. If you only *read* tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables.

For `mysqld`, external locking is controlled by the value of the `skip_external_locking` system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.

Use of external locking can be controlled at server startup by using the `--external-locking` or `--skip-external-locking` option.

If you do use external locking option to enable updates to `MyISAM` tables from many MySQL processes, do not start the server with the `delay_key_write` system variable set to `ALL` or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy this condition is to always use `--external-locking` together with `--delay-key-write=OFF`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

8.12 Optimizing the MySQL Server

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

8.12.1 Optimizing Disk I/O

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server. For information about optimizing an `InnoDB` configuration to improve I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.
- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
 - Using symbolic links

This means that, for `MyISAM` tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See [Section 8.12.2, “Using Symbolic Links”](#).

Symbolic links are not supported for use with [InnoDB](#) tables. However, it is possible to place [InnoDB](#) data and log files on different physical disks. For more information, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- Striping

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the N -th block on the $(N \bmod \text{number_of_disks})$ disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See [Section 8.13.2, “Using Your Own Benchmarks”](#).

The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need $2 \times N$ drives to hold N drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.
- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID N disk. RAID N can be a problem if you have many writes, due to the time required to update the parity bits.
- You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

Using NFS with MySQL

You should be cautious when considering whether to use NFS with MySQL. Potential issues, which vary by operating system and NFS version, include the following:

- MySQL data and log files placed on NFS volumes becoming locked and unavailable for use. Locking issues may occur in cases where multiple instances of MySQL access the same data directory or where MySQL is shut down improperly, due to a power outage, for example. NFS version 4 addresses underlying locking issues with the introduction of advisory and lease-based locking. However, sharing a data directory among MySQL instances is not recommended.
- Data inconsistencies introduced due to messages received out of order or lost network traffic. To avoid this issue, use TCP with `hard` and `intr` mount options.
- Maximum file size limitations. NFS Version 2 clients can only access the lowest 2GB of a file (signed 32 bit offset). NFS Version 3 clients support larger files (up to 64 bit offsets). The maximum supported file size also depends on the local file system of the NFS server.

Using NFS within a professional SAN environment or other storage system tends to offer greater reliability than using NFS outside of such an environment. However, NFS within a SAN environment may be slower than directly attached or bus-attached non-rotational storage.

If you choose to use NFS, NFS Version 4 or later is recommended, as is testing your NFS setup thoroughly before deploying into a production environment.

8.12.2 Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

For **InnoDB** tables, use the `DATA DIRECTORY` clause of the `CREATE TABLE` statement instead of symbolic links, as explained in [Section 15.6.1.2, “Creating Tables Externally”](#). This new feature is a supported, cross-platform technique.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink **MyISAM** tables only as a last resort.

To determine the location of your data directory, use this statement:

```
SHOW VARIABLES LIKE 'datadir';
```

8.12.2.1 Using Symbolic Links for Databases on Unix

On Unix, symlink a database using this procedure:

1. Create the database using `CREATE DATABASE`:

```
mysql> CREATE DATABASE mydb1;
```

Using `CREATE DATABASE` creates the database in the MySQL data directory and permits the server to update the data dictionary with information about the database directory.

2. Stop the server to ensure that no activity occurs in the new database while it is being moved.
3. Move the database directory to some disk where you have free space. For example, use `tar` or `mv`. If you use a method that copies rather than moves the database directory, remove the original database directory after copying it.
4. Create a soft link in the data directory to the moved database directory:

```
shell> ln -s /path/to/mydb1 /path/to/datadir
```

The command creates a symlink named `mydb1` in the data directory.

5. Restart the server.

8.12.2.2 Using Symbolic Links for MyISAM Tables on Unix

Note

Symbolic link support as described here, along with the `--symbolic-links` option that controls it, is deprecated and will be removed in a future version of MySQL. In addition, the option is disabled by default.

Symlinks are fully supported only for **MyISAM** tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links. For **InnoDB** tables, use the alternative technique explained in [Section 15.6.1.2, “Creating Tables Externally”](#) instead.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). To determine whether your system supports symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

The handling of symbolic links for **MyISAM** tables works as follows:

- In the data directory, you always have the data (`.MYD`) file and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks.
- You can symlink the data file and the index file independently to different directories.
- To instruct a running MySQL server to perform the symlinking, use the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See [Section 13.1.20, “CREATE TABLE Statement”](#). Alternatively, if `mysqld` is not running, symlinking can be accomplished manually using `ln -s` from the command line.

**Note**

The path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL `data` directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

**Note**

When you drop a table that is using symlinks, *both the symlink and the file to which the symlink points are dropped*. This is an extremely good reason *not* to run `mysqld` as the `root` operating system user or permit operating system users to have write access to MySQL database directories.

- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you are not using symlinks, start `mysqld` with the `--skip-symbolic-links` option to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.

8.12.2.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named `mydb` at `D:\data\mydb`. To do this, create a symbolic link in the MySQL data directory that points to `D:\data\mydb`. However, before creating the symbolic link, make sure that the `D:\data\mydb` directory exists by creating it if necessary. If you already have a database directory named `mydb` in the data directory, move it to `D:\data`. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.

On Windows, you can create a symlink using the `mklink` command. This command requires administrative privileges.

1. Change location into the data directory:

```
C:\> cd \path\to\datadir
```

2. In the data directory, create a symlink named `mydb` that points to the location of the database directory:

```
C:\> mklink /d mydb D:\data\mydb
```

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

8.12.3 Optimizing Memory Use

8.12.3.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. The default configuration is designed to permit a MySQL server to start on a virtual machine that has approximately 512MB of RAM. You can improve MySQL performance by increasing the values of certain cache and buffer-related system variables. You can also modify the default configuration to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine or feature specific.

- The `InnoDB` buffer pool is a memory area that holds cached `InnoDB` data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into `pages` that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the `LRU` algorithm. For more information, see [Section 15.5.1, “Buffer Pool”](#).

The size of the buffer pool is important for system performance:

- `InnoDB` allocates memory for the entire buffer pool at server startup, using `malloc()` operations. The `innodb_buffer_pool_size` system variable defines the buffer pool size. Typically, a recommended `innodb_buffer_pool_size` value is 50 to 75 percent of system memory. `innodb_buffer_pool_size` can be configured dynamically, while the server is running. For more information, see [Section 15.8.3.1, “Configuring InnoDB Buffer Pool Size”](#).
- On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple `buffer pool instances`. The `innodb_buffer_pool_instances` system variable defines the number of buffer pool instances.
- A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.
- A buffer pool that is too large may cause swapping due to competition for memory.
- The storage engine interface enables the optimizer to provide information about the size of the record buffer to be used for scans that the optimizer estimates will read multiple rows. The buffer size can vary based on the size of the estimate. `InnoDB` uses this variable-size buffering capability to take advantage of row prefetching, and to reduce the overhead of latching and B-tree navigation.
- All threads share the `MyISAM` key buffer. The `key_buffer_size` system variable determines its size.

For each `MyISAM` table the server opens, the index file is opened once; the data file is opened once for each concurrently running thread that accesses the table. For each concurrent thread, a table structure, column structures for each column, and a buffer of size $3 * N$ are allocated (where N is the maximum row length, not counting `BLOB` columns). A `BLOB` column requires five to eight bytes plus the length of the `BLOB` data. The `MyISAM` storage engine maintains one extra row buffer for internal use.

- The `myisam_use_mmap` system variable can be set to 1 to enable memory-mapping for all `MyISAM` tables.
- If an internal in-memory temporary table becomes too large (as determined using the `tmp_table_size` and `max_heap_table_size` system variables), MySQL automatically converts the table from in-memory to on-disk format. As of MySQL 8.0.16, on-disk temporary tables always use the InnoDB storage engine. (Previously, the storage engine employed for this purpose was determined by the `internal_tmp_disk_storage_engine` system variable, which is no longer supported.) You can increase the permissible temporary table size as described in [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

For `MEMORY` tables explicitly created with `CREATE TABLE`, only the `max_heap_table_size` system variable determines how large a table can grow, and there is no conversion to on-disk format.

- The [MySQL Performance Schema](#) is a feature for monitoring MySQL server execution at a low level. The Performance Schema dynamically allocates memory incrementally, scaling its memory use to actual server load, instead of allocating required memory during server startup. Once memory is allocated, it is not freed until the server is restarted. For more information, see [Section 26.17, “The Performance Schema Memory-Allocation Model”](#).
- Each thread that the server uses to manage client connections requires some thread-specific space. The following list indicates these and which system variables control their size:
 - A stack (`thread_stack`)
 - A connection buffer (`net_buffer_length`)
 - A result buffer (`net_buffer_length`)

The connection buffer and result buffer each begin with a size equal to `net_buffer_length` bytes, but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

Each connection thread uses memory for computing statement digests. The server allocates `max_digest_length` bytes per session. See [Section 26.10, “Performance Schema Statement Digests and Sampling”](#).

- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.
- Each request that performs a sequential scan of a table allocates a *read buffer*. The `read_buffer_size` system variable determines the buffer size.
- When reading rows in an arbitrary sequence (for example, following a sort), a *random-read buffer* may be allocated to avoid disk seeks. The `read_rnd_buffer_size` system variable determines the buffer size.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain `BLOB` columns are stored on disk.
- Most requests that perform a sort allocate a sort buffer and zero to two temporary files depending on the result set size. See [Section B.3.3.5, “Where MySQL Stores Temporary Files”](#).
- Almost all parsing and calculating is done in thread-local and reusable memory pools. No memory overhead is needed for small items, thus avoiding the normal slow memory allocation and freeing. Memory is allocated only for unexpectedly large strings.

- For each table having `BLOB` columns, a buffer is enlarged dynamically to read in larger `BLOB` values. If you scan a table, the buffer grows as large as the largest `BLOB` value.
- MySQL requires memory and descriptors for the table cache. Handler structures for all in-use tables are saved in the table cache and managed as “First In, First Out” (FIFO). The `table_open_cache` system variable defines the initial table cache size; see [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).

MySQL also requires memory for the table definition cache. The `table_definition_cache` system variable defines the number of table definitions that can be stored in the table definition cache. If you use a large number of tables, you can create a large table definition cache to speed up the opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the table cache.

- A `FLUSH TABLES` statement or `mysqladmin flush-tables` command closes all tables that are not in use at once and marks all in-use tables to be closed when the currently executing thread finishes. This effectively frees most in-use memory. `FLUSH TABLES` does not return until all tables have been closed.
- The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in cached memory use unless it is freed with `FLUSH PRIVILEGES`.
- In a replication topology, the following settings affect memory usage, and can be adjusted as required:
 - The `max_allowed_packet` system variable on a replication source limits the maximum message size that the source sends to its replicas for processing. This setting defaults to 64M.
 - The `slave_pending_jobs_size_max` system variable on a multithreaded replica sets the maximum amount of memory that is made available for holding messages awaiting processing. This setting defaults to 128M. The memory is only allocated when needed, but it might be used if your replication topology handles large transactions sometimes. It is a soft limit, and larger transactions can be processed.
 - The `rpl_read_size` system variable on a replication source or replica controls the minimum amount of data in bytes that is read from the binary log files and relay log files. The default is 8192 bytes. A buffer the size of this value is allocated for each thread that reads from the binary log and relay log files, including dump threads on sources and coordinator threads on replicas.
 - The `binlog_transaction_dependency_history_size` system variable limits the number of row hashes held as an in-memory history.
 - The `max_binlog_cache_size` system variable specifies the upper limit of memory usage by an individual transaction.
 - The `max_binlog_stmt_cache_size` system variable specifies the upper limit of memory usage by the statement cache.

`ps` and other system status programs may report that `mysqld` uses a lot of memory. This may be caused by thread stacks on different memory addresses. For example, the Solaris version of `ps` counts the unused memory between stacks as used memory. To verify this, check available swap with `swap -s`. We test `mysqld` with several memory-leakage detectors (both commercial and Open Source), so there should be no memory leaks.

Monitoring MySQL Memory Usage

The following example demonstrates how to use [Performance Schema](#) and [sys schema](#) to monitor MySQL memory usage.

Most Performance Schema memory instrumentation is disabled by default. Instruments can be enabled by updating the `ENABLED` column of the Performance Schema `setup_instruments` table. Memory instruments have names in the form of `memory/code_area/instrument_name`, where `code_area` is a value such as `sql` or `innodb`, and `instrument_name` is the instrument detail.

1. To view available MySQL memory instruments, query the Performance Schema `setup_instruments` table. The following query returns hundreds of memory instruments for all code areas.

```
mysql> SELECT * FROM performance_schema.setup_instruments
      WHERE NAME LIKE '%memory%';
```

You can narrow results by specifying a code area. For example, you can limit results to `InnoDB` memory instruments by specifying `innodb` as the code area.

```
mysql> SELECT * FROM performance_schema.setup_instruments
      WHERE NAME LIKE '%memory/innodb%';
```

NAME	ENABLED	TIMED
memory/innodb/adaptive hash index	NO	NO
memory/innodb/buf_buf_pool	NO	NO
memory/innodb/dict_stats_bg_recalc_pool_t	NO	NO
memory/innodb/dict_stats_index_map_t	NO	NO
memory/innodb/dict_stats_n_diff_on_level	NO	NO
memory/innodb/other	NO	NO
memory/innodb/row_log_buf	NO	NO
memory/innodb/row_merge_sort	NO	NO
memory/innodb/std	NO	NO
memory/innodb/trx_sys_t::rw_trx_ids	NO	NO
...		

Depending on your MySQL installation, code areas may include `performance_schema`, `sql`, `client`, `innodb`, `myisam`, `csv`, `memory`, `blackhole`, `archive`, `partition`, and others.

2. To enable memory instruments, add a `performance-schema-instrument` rule to your MySQL configuration file. For example, to enable all memory instruments, add this rule to your configuration file and restart the server:

```
performance-schema-instrument='memory/%=COUNTED'
```

Note

Enabling memory instruments at startup ensures that memory allocations that occur at startup are counted.

After restarting the server, the `ENABLED` column of the Performance Schema `setup_instruments` table should report `YES` for memory instruments that you enabled. The `TIMED` column in the `setup_instruments` table is ignored for memory instruments because memory operations are not timed.

```
mysql> SELECT * FROM performance_schema.setup_instruments
      WHERE NAME LIKE '%memory/innodb%';
```

NAME	ENABLED	TIMED
memory/innodb/adaptive hash index	NO	NO
memory/innodb/buf_buf_pool	NO	NO
memory/innodb/dict_stats_bg_recalc_pool_t	NO	NO
memory/innodb/dict_stats_index_map_t	NO	NO
memory/innodb/dict_stats_n_diff_on_level	NO	NO
memory/innodb/other	NO	NO
memory/innodb/row_log_buf	NO	NO
memory/innodb/row_merge_sort	NO	NO
memory/innodb/std	NO	NO
memory/innodb/trx_sys_t::rw_trx_ids	NO	NO
...		

- Query memory instrument data. In this example, memory instrument data is queried in the Performance Schema `memory_summary_global_by_event_name` table, which summarizes data by `EVENT_NAME`. The `EVENT_NAME` is the name of the instrument.

The following query returns memory data for the `InnoDB` buffer pool. For column descriptions, see [Section 26.12.18.10, “Memory Summary Tables”](#).

```
mysql> SELECT * FROM performance_schema.memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/innodb/buf_buf_pool'
      EVENT_NAME: memory/innodb/buf_buf_pool
      COUNT_ALLOC: 1
      COUNT_FREE: 0
SUM_NUMBER_OF_BYTES_ALLOC: 137428992
SUM_NUMBER_OF_BYTES_FREE: 0
      LOW_COUNT_USED: 0
      CURRENT_COUNT_USED: 1
      HIGH_COUNT_USED: 1
      LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 137428992
      HIGH_NUMBER_OF_BYTES_USED: 137428992
```

The same underlying data can be queried using the `sys` schema `memory_global_by_current_bytes` table, which shows current memory usage within the server globally, broken down by allocation type.

```
mysql> SELECT * FROM sys.memory_global_by_current_bytes
WHERE event_name LIKE 'memory/innodb/buf_buf_pool'\G
***** 1. row *****
      event_name: memory/innodb/buf_buf_pool
      current_count: 1
      current_alloc: 131.06 MiB
current_avg_alloc: 131.06 MiB
      high_count: 1
      high_alloc: 131.06 MiB
      high_avg_alloc: 131.06 MiB
```

This `sys` schema query aggregates currently allocated memory (`current_alloc`) by code area:

```
mysql> SELECT SUBSTRING_INDEX(event_name,'/',2) AS
      code_area, FORMAT_BYTES(SUM(current_alloc))
      AS current_alloc
FROM sys.x$memory_global_by_current_bytes
GROUP BY SUBSTRING_INDEX(event_name,'/',2)
ORDER BY SUM(current_alloc) DESC;
```

code_area	current_alloc
memory/innodb	843.24 MiB
memory/performance_schema	81.29 MiB
memory/mysys	8.20 MiB
memory/sql	2.47 MiB
memory/memory	174.01 KiB
memory/myisam	46.53 KiB
memory/blackhole	512 bytes
memory/federated	512 bytes
memory/csv	512 bytes
memory/vio	496 bytes

Note

Prior to MySQL 8.0.16, `sys.format_bytes()` was used for `FORMAT_BYTES()`.

For more information about `sys` schema, see [Chapter 27, MySQL sys Schema](#).

8.12.3.2 Enabling Large Page Support

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

In MySQL, large pages can be used by InnoDB, to allocate memory for its buffer pool and additional memory pool.

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

MySQL also supports the Linux implementation of large page support (which is called HugeTLB in Linux).

Before large pages can be used on Linux, the kernel must be enabled to support them and it is necessary to configure the HugeTLB memory pool. For reference, the HugeTBL API is documented in the [Documentation/vm/hugetlbpage.txt](#) file of your Linux sources.

The kernel for some recent systems such as Red Hat Enterprise Linux appear to have the large pages feature enabled by default. To check whether this is true for your kernel, use the following command and look for output lines containing “huge”:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      0
HugePages_Free:       0
HugePages_Rsvd:       0
HugePages_Surp:       0
Hugepagesize:        4096 kB
```

The nonempty command output indicates that large page support is present, but the zero values indicate that no pages are configured for use.

If your kernel needs to be reconfigured to support large pages, consult the [hugetlbpage.txt](#) file for instructions.

Assuming that your Linux kernel has large page support enabled, configure it for use by MySQL using the following commands. Normally, you put these in an `rc` file or equivalent startup file that is executed during the system boot sequence, so that the commands execute each time the system starts. The commands should execute early in the boot sequence, before the MySQL server starts. Be sure to change the allocation numbers and the group number as appropriate for your system.

```
# Set the number of pages to be used.
# Each page is normally 2MB, so a value of 20 = 40MB.
# This command actually allocates memory, so this much
# memory must be available.
echo 20 > /proc/sys/vm/nr_hugepages

# Set the group number that is permitted to access this
# memory (102 in this case). The mysql user must be a
# member of this group.
echo 102 > /proc/sys/vm/hugetlb_shm_group

# Increase the amount of shmem permitted per segment
# (12G in this case).
echo 1560281088 > /proc/sys/kernel/shmmax

# Increase total amount of shared memory. The value
# is the number of pages. At 4KB/page, 4194304 = 16GB.
echo 4194304 > /proc/sys/kernel/shmall
```

For MySQL usage, you normally want the value of `shmmax` to be close to the value of `shmall`.

To verify the large page configuration, check `/proc/meminfo` again as described previously. Now you should see some nonzero values:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:       0
HugePages_Surp:       0
Hugepagesize:         4096 kB
```

The final step to make use of the `hugetlb_shm_group` is to give the `mysql` user an “unlimited” value for the memlock limit. This can be done either by editing `/etc/security/limits.conf` or by adding the following command to your `mysqld_safe` script:

```
ulimit -l unlimited
```

Adding the `ulimit` command to `mysqld_safe` causes the `root` user to set the memlock limit to `unlimited` before switching to the `mysql` user. (This assumes that `mysqld_safe` is started by `root`.)

Large page support in MySQL is disabled by default. To enable it, start the server with the `--large-pages` option. For example, you can use the following lines in the server `my.cnf` file:

```
[mysqld]
large-pages
```

With this option, `InnoDB` uses large pages automatically for its buffer pool and additional memory pool. If `InnoDB` cannot do this, it falls back to use of traditional memory and writes a warning to the error log: `Warning: Using conventional memory pool`

To verify that large pages are being used, check `/proc/meminfo` again:

```
shell> cat /proc/meminfo | grep -i huge
HugePages_Total:      20
HugePages_Free:       20
HugePages_Rsvd:       2
HugePages_Surp:       0
Hugepagesize:         4096 kB
```

8.13 Measuring Performance (Benchmarking)

To measure performance, consider the following factors:

- Whether you are measuring the speed of a single operation on a quiet system, or how a set of operations (a “workload”) works over a period of time. With simple tests, you usually test how changing one aspect (a configuration setting, the set of indexes on a table, the SQL clauses in a query) affects performance. Benchmarks are typically long-running and elaborate performance tests, where the results could dictate high-level choices such as hardware and storage configuration, or how soon to upgrade to a new MySQL version.
- For benchmarking, sometimes you must simulate a heavy database workload to get an accurate picture.
- Performance can vary depending on so many different factors that a difference of a few percentage points might not be a decisive victory. The results might shift the opposite way when you test in a different environment.
- Certain MySQL features help or do not help performance depending on the workload. For completeness, always test performance with those features turned on and turned off. The most important feature to try with each workload is the `adaptive hash index` for `InnoDB` tables.

This section progresses from simple and direct measurement techniques that a single developer can do, to more complicated ones that require additional expertise to perform and interpret the results.

8.13.1 Measuring the Speed of Expressions and Functions

To measure the speed of a specific MySQL expression or function, invoke the `BENCHMARK()` function using the `mysql` client program. Its syntax is `BENCHMARK(loop_count,expr)`. The return value is

always zero, but `mysql` prints a line displaying approximately how long the statement took to execute. For example:

```
mysql> SELECT BENCHMARK(1000000,1+1);
+-----+
| BENCHMARK(1000000,1+1) |
+-----+
| 0 |
+-----+
1 row in set (0.32 sec)
```

This result was obtained on a Pentium II 400MHz system. It shows that MySQL can execute 1,000,000 simple addition expressions in 0.32 seconds on that system.

The built-in MySQL functions are typically highly optimized, but there may be some exceptions. `BENCHMARK()` is an excellent tool for finding out if some function is a problem for your queries.

8.13.2 Using Your Own Benchmarks

Benchmark your application and database to find out where the bottlenecks are. After fixing one bottleneck (or by replacing it with a “dummy” module), you can proceed to identify the next bottleneck. Even if the overall performance for your application currently is acceptable, you should at least make a plan for each bottleneck and decide how to solve it if someday you really need the extra performance.

A free benchmark suite is the Open Source Database Benchmark, available at <http://osdb.sourceforge.net/>.

It is very common for a problem to occur only when the system is very heavily loaded. We have had many customers who contact us when they have a (tested) system in production and have encountered load problems. In most cases, performance problems turn out to be due to issues of basic database design (for example, table scans are not good under high load) or problems with the operating system or libraries. Most of the time, these problems would be much easier to fix if the systems were not already in production.

To avoid problems like this, benchmark your whole application under the worst possible load:

- The `mysqlslap` program can be helpful for simulating a high load produced by multiple clients issuing queries simultaneously. See [Section 4.5.8, “mysqlslap — A Load Emulation Client”](#).
- You can also try benchmarking packages such as SysBench and DBT2, available at <https://launchpad.net/sysbench>, and <http://osdldb.sourceforge.net/#dbt2>.

These programs or packages can bring a system to its knees, so be sure to use them only on your development systems.

8.13.3 Measuring Performance with `performance_schema`

You can query the tables in the `performance_schema` database to see real-time information about the performance characteristics of your server and the applications it is running. See [Chapter 26, MySQL Performance Schema](#) for details.

8.14 Examining Server Thread (Process) Information

To ascertain what your MySQL server is doing, it can be helpful to examine the process list, which indicates the operations currently being performed by the set of threads executing within the server. For example:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 5
  User: event_scheduler
  Host: localhost
```

```

db: NULL
Command: Daemon
Time: 2756681
State: Waiting on empty queue
Info: NULL
***** 2. row *****
Id: 20
User: me
Host: localhost:52943
db: test
Command: Query
Time: 0
State: starting
Info: SHOW PROCESSLIST

```

Threads can be killed with the `KILL` statement. See [Section 13.7.8.4, “KILL Statement”](#).

8.14.1 Accessing the Process List

The following discussion enumerates the sources of process information, the privileges required to see process information, and describes the content of process list entries.

- [Sources of Process Information](#)
- [Privileges Required to Access the Process List](#)
- [Content of Process List Entries](#)

Sources of Process Information

Process information is available from these sources:

- The `SHOW PROCESSLIST` statement: [Section 13.7.7.29, “SHOW PROCESSLIST Statement”](#)
- The `mysqladmin processlist` command: [Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”](#)
- The `INFORMATION_SCHEMA PROCESSLIST` table: [Section 25.23, “The INFORMATION_SCHEMA PROCESSLIST Table”](#)
- The Performance Schema `processlist` table: [Section 26.12.19.6, “The processlist Table”](#)
- The Performance Schema `threads` table columns with names having a prefix of `PROCESSLIST_`: [Section 26.12.19.7, “The threads Table”](#)
- The `sys` schema `processlist` and `session` views: [Section 27.4.3.22, “The processlist and x\\$processlist Views”](#), and [Section 27.4.3.33, “The session and x\\$session Views”](#)

The `threads` table compares to `SHOW PROCESSLIST`, `INFORMATION_SCHEMA PROCESSLIST`, and `mysqladmin processlist` as follows:

- Access to the `threads` table does not require a mutex and has minimal impact on server performance. The other sources have negative performance consequences because they require a mutex.

Note

As of MySQL 8.0.22, an alternative implementation for `SHOW PROCESSLIST` is available based on the Performance Schema `processlist` table, which, like the `threads` table, does not require a mutex and has better performance characteristics. For details, see [Section 26.12.19.6, “The processlist Table”](#).

- The `threads` table displays background threads, which the other sources do not. It also provides additional information for each thread that the other sources do not, such as whether the thread is a

foreground or background thread, and the location within the server associated with the thread. This means that the `threads` table can be used to monitor thread activity the other sources cannot.

- You can enable or disable Performance Schema thread monitoring, as described in [Section 26.12.19.7, “The threads Table”](#).

For these reasons, DBAs who perform server monitoring using one of the other thread information sources may wish to monitor using the `threads` table instead.

The `sys` schema `processlist` view presents information from the Performance Schema `threads` table in a more accessible format. The `sys` schema `session` view presents information about user sessions like the `sys` schema `processlist` view, but with background processes filtered out.

Privileges Required to Access the Process List

For most sources of process information, if you have the `PROCESS` privilege, you can see all threads, even those belonging to other users. Otherwise (without the `PROCESS` privilege), nonanonymous users have access to information about their own threads but not threads for other users, and anonymous users have no access to thread information.

The Performance Schema `threads` table also provides thread information, but table access uses a different privilege model. See [Section 26.12.19.7, “The threads Table”](#).

Content of Process List Entries

Each process list entry contains several pieces of information. The following list describes them using the labels from `SHOW PROCESSLIST` output. Other process information sources use similar labels.

- `Id` is the connection identifier for the client associated with the thread.
- `User` and `Host` indicate the account associated with the thread.
- `db` is the default database for the thread, or `NULL` if none has been selected.
- `Command` and `State` indicate what the thread is doing.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

The following sections list the possible `Command` values, and `State` values grouped by category. The meaning for some of these values is self-evident. For others, additional description is provided.

Note

Applications that examine process list information should be aware that the commands and states are subject to change.

- `Time` indicates how long the thread has been in its current state. The thread's notion of the current time may be altered in some cases: The thread can change the time with `SET TIMESTAMP = value`. For a replica SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the replica host. See [Section 17.2.3, “Replication Threads”](#).
- `Info` indicates the statement the thread is executing, or `NULL` if it is executing no statement. For `SHOW PROCESSLIST`, this value contains only the first 100 characters of the statement. To see complete statements, use `SHOW FULL PROCESSLIST` (or query a different process information source).

8.14.2 Thread Command Values

A thread can have any of the following `Command` values:

- `Binlog Dump`

This is a thread on a replication source for sending binary log contents to a replica.

- `Change user`

The thread is executing a change-user operation.

- `Close stmt`

The thread is closing a prepared statement.

- `Connect`

A replica is connected to its source.

- `Connect Out`

A replica is connecting to its source.

- `Create DB`

The thread is executing a create-database operation.

- `Daemon`

This thread is internal to the server, not a thread that services a client connection.

- `Debug`

The thread is generating debugging information.

- `Delayed insert`

The thread is a delayed-insert handler.

- `Drop DB`

The thread is executing a drop-database operation.

- `Error`

- `Execute`

The thread is executing a prepared statement.

- `Fetch`

The thread is fetching the results from executing a prepared statement.

- `Field List`

The thread is retrieving information for table columns.

- `Init DB`

The thread is selecting a default database.

- `Kill`

The thread is killing another thread.

- `Long Data`

The thread is retrieving long data in the result of executing a prepared statement.

- `Ping`

The thread is handling a server-ping request.

- `Prepare`

The thread is preparing a prepared statement.

- `Processlist`

The thread is producing information about server threads.

- `Query`

The thread is executing a statement.

- `Quit`

The thread is terminating.

- `Refresh`

The thread is flushing table, logs, or caches, or resetting status variable or replication server information.

- `Register Slave`

The thread is registering a replica server.

- `Reset stmt`

The thread is resetting a prepared statement.

- `Set option`

The thread is setting or resetting a client statement-execution option.

- `Shutdown`

The thread is shutting down the server.

- `Sleep`

The thread is waiting for the client to send a new statement to it.

- `Statistics`

The thread is producing server-status information.

- `Table Dump`

The thread is sending table contents to a replica.

- `Time`

Unused.

8.14.3 General Thread States

The following list describes thread `State` values that are associated with general query processing and not more specialized activities such as replication. Many of these are useful only for finding bugs in the server.

- `After create`

This occurs when the thread creates a table (including internal temporary tables), at the end of the function that creates the table. This state is used even if the table could not be created due to some error.

- `altering table`

The server is in the process of executing an in-place `ALTER TABLE`.

- `Analyzing`

The thread is calculating a `MyISAM` table key distributions (for example, for `ANALYZE TABLE`).

- `checking permissions`

The thread is checking whether the server has the required privileges to execute the statement.

- `Checking table`

The thread is performing a table check operation.

- `cleaning up`

The thread has processed one command and is preparing to free memory and reset certain state variables.

- `closing tables`

The thread is flushing the changed table data to disk and closing the used tables. This should be a fast operation. If not, verify that you do not have a full disk and that the disk is not in very heavy use.

- `converting HEAP to ondisk`

The thread is converting an internal temporary table from a `MEMORY` table to an on-disk table.

- `copy to tmp table`

The thread is processing an `ALTER TABLE` statement. This state occurs after the table with the new structure has been created but before rows are copied into it.

For a thread in this state, the Performance Schema can be used to obtain about the progress of the copy operation. See [Section 26.12.5, “Performance Schema Stage Event Tables”](#).

- `Copying to group table`

If a statement has different `ORDER BY` and `GROUP BY` criteria, the rows are sorted by group and copied to a temporary table.

- `Copying to tmp table`

The server is copying to a temporary table in memory.

- `Copying to tmp table on disk`

The server is copying to a temporary table on disk. The temporary result set has become too large (see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#)). Consequently, the thread is changing the temporary table from in-memory to disk-based format to save memory.

- `Creating index`

The thread is processing `ALTER TABLE ... ENABLE KEYS` for a `MyISAM` table.

- `Creating sort index`

The thread is processing a `SELECT` that is resolved using an internal temporary table.

- `creating table`

The thread is creating a table. This includes creation of temporary tables.

- `Creating tmp table`

The thread is creating a temporary table in memory or on disk. If the table is created in memory but later is converted to an on-disk table, the state during that operation will be `Copying to tmp table on disk`.

- `committing alter table to storage engine`

The server has finished an in-place `ALTER TABLE` and is committing the result.

- `deleting from main table`

The server is executing the first part of a multiple-table delete. It is deleting only from the first table, and saving columns and offsets to be used for deleting from the other (reference) tables.

- `deleting from reference tables`

The server is executing the second part of a multiple-table delete and deleting the matched rows from the other tables.

- `discard_or_import_tablespace`

The thread is processing an `ALTER TABLE ... DISCARD TABLESPACE` or `ALTER TABLE ... IMPORT TABLESPACE` statement.

- `end`

This occurs at the end but before the cleanup of `ALTER TABLE`, `CREATE VIEW`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements.

For the `end` state, the following operations could be happening:

- Writing an event to the binary log
- Freeing memory buffers, including for blobs
- `executing`

The thread has begun executing a statement.

- `Execution of init_command`

The thread is executing statements in the value of the `init_command` system variable.

- `freeing items`

The thread has executed a command. This state is usually followed by `cleaning up`.

- `FULLTEXT initialization`

The server is preparing to perform a natural-language full-text search.

- `init`

This occurs before the initialization of `ALTER TABLE`, `DELETE`, `INSERT`, `SELECT`, or `UPDATE` statements. Actions taken by the server in this state include flushing the binary log and the `InnoDB` log.

- `Killed`

Someone has sent a `KILL` statement to the thread and it should abort next time it checks the kill flag. The flag is checked in each major loop in MySQL, but in some cases it might still take a short time for the thread to die. If the thread is locked by some other thread, the kill takes effect as soon as the other thread releases its lock.

- `Locking system tables`

The thread is trying to lock a system table (for example, a time zone or log table).

- `logging slow query`

The thread is writing a statement to the slow-query log.

- `login`

The initial state for a connection thread until the client has been authenticated successfully.

- `manage keys`

The server is enabling or disabling a table index.

- `Opening system tables`

The thread is trying to open a system table (for example, a time zone or log table).

- `Opening tables`

The thread is trying to open a table. This is should be very fast procedure, unless something prevents opening. For example, an `ALTER TABLE` or a `LOCK TABLE` statement can prevent opening a table until the statement is finished. It is also worth checking that your `table_open_cache` value is large enough.

For system tables, the `Opening system tables` state is used instead.

- `optimizing`

The server is performing initial optimizations for a query.

- `preparing`

This state occurs during query optimization.

- `Purging old relay logs`

The thread is removing unneeded relay log files.

- `query end`

This state occurs after processing a query but before the `freeing items` state.

- `Receiving from client`

The server is reading a packet from the client.

- `Removing duplicates`

The query was using `SELECT DISTINCT` in such a way that MySQL could not optimize away the distinct operation at an early stage. Because of this, MySQL requires an extra stage to remove all duplicated rows before sending the result to the client.

- `removing tmp table`

The thread is removing an internal temporary table after processing a `SELECT` statement. This state is not used if no temporary table was created.

- `rename`

The thread is renaming a table.

- `rename result table`

The thread is processing an `ALTER TABLE` statement, has created the new table, and is renaming it to replace the original table.

- `Reopen tables`

The thread got a lock for the table, but noticed after getting the lock that the underlying table structure changed. It has freed the lock, closed the table, and is trying to reopen it.

- `Repair by sorting`

The repair code is using a sort to create indexes.

- `preparing for alter table`

The server is preparing to execute an in-place `ALTER TABLE`.

- `Repair done`

The thread has completed a multithreaded repair for a `MyISAM` table.

- `Repair with keycache`

The repair code is using creating keys one by one through the key cache. This is much slower than `Repair by sorting`.

- `Rolling back`

The thread is rolling back a transaction.

- `Saving state`

For `MyISAM` table operations such as repair or analysis, the thread is saving the new table state to the `.MYI` file header. State includes information such as number of rows, the `AUTO_INCREMENT` counter, and key distributions.

- `Searching rows for update`

The thread is doing a first phase to find all matching rows before updating them. This has to be done if the `UPDATE` is changing the index that is used to find the involved rows.

- `Sending data`

The thread is reading and processing rows for a `SELECT` statement, and sending data to the client. Because operations occurring during this state tend to perform large amounts of disk access (reads), it is often the longest-running state over the lifetime of a given query.

- `Sending to client`

The server is writing a packet to the client.

- `setup`

The thread is beginning an `ALTER TABLE` operation.

- `Sorting for group`

The thread is doing a sort to satisfy a `GROUP BY`.

- `Sorting for order`

The thread is doing a sort to satisfy an `ORDER BY`.

- `Sorting index`

The thread is sorting index pages for more efficient access during a `MyISAM` table optimization operation.

- `Sorting result`

For a `SELECT` statement, this is similar to `Creating sort index`, but for nontemporary tables.

- `starting`

The first stage at the beginning of statement execution.

- `statistics`

The server is calculating statistics to develop a query execution plan. If a thread is in this state for a long time, the server is probably disk-bound performing other work.

- `System lock`

The thread has called `mysql_lock_tables()` and the thread state has not been updated since. This is a very general state that can occur for many reasons.

For example, the thread is going to request or is waiting for an internal or external system lock for the table. This can occur when `InnoDB` waits for a table-level lock during execution of `LOCK TABLES`. If this state is being caused by requests for external locks and you are not using multiple `mysqld` servers that are accessing the same `MyISAM` tables, you can disable external system locks with the `--skip-external-locking` option. However, external locking is disabled by default, so it is likely that this option will have no effect. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

For system tables, the `Locking system tables` state is used instead.

- `update`

The thread is getting ready to start updating the table.

- `Updating`

The thread is searching for rows to update and is updating them.

- `updating main table`

The server is executing the first part of a multiple-table update. It is updating only the first table, and saving columns and offsets to be used for updating the other (reference) tables.

- `updating reference tables`

The server is executing the second part of a multiple-table update and updating the matched rows from the other tables.

- `User lock`

The thread is going to request or is waiting for an advisory lock requested with a `GET_LOCK()` call. For `SHOW PROFILE`, this state means the thread is requesting the lock (not waiting for it).

- `User sleep`

The thread has invoked a `SLEEP()` call.

- `Waiting for commit lock`

`FLUSH TABLES WITH READ LOCK` is waiting for a commit lock.

- `waiting for handler commit`

The thread is waiting for a transaction to commit versus other parts of query processing.

- `Waiting for tables`

The thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for table flush`

The thread is executing `FLUSH TABLES` and is waiting for all threads to close their tables, or the thread got a notification that the underlying structure for a table has changed and it needs to reopen the table to get the new structure. However, to reopen the table, it must wait until all other threads have closed the table in question.

This notification takes place if another thread has used `FLUSH TABLES` or one of the following statements on the table in question: `FLUSH TABLES tbl_name`, `ALTER TABLE`, `RENAME TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, or `OPTIMIZE TABLE`.

- `Waiting for lock_type lock`

The server is waiting to acquire a `THR_LOCK` lock or a lock from the metadata locking subsystem, where `lock_type` indicates the type of lock.

This state indicates a wait for a `THR_LOCK`:

- `Waiting for table level lock`

These states indicate a wait for a metadata lock:

- `Waiting for event metadata lock`
- `Waiting for global read lock`
- `Waiting for schema metadata lock`
- `Waiting for stored function metadata lock`
- `Waiting for stored procedure metadata lock`
- `Waiting for table metadata lock`
- `Waiting for trigger metadata lock`

For information about table lock indicators, see [Section 8.11.1, “Internal Locking Methods”](#). For information about metadata locking, see [Section 8.11.4, “Metadata Locking”](#). To see which locks are blocking lock requests, use the Performance Schema lock tables described at [Section 26.12.13, “Performance Schema Lock Tables”](#).

- `Waiting on cond`

A generic state in which the thread is waiting for a condition to become true. No specific state information is available.

- `Writing to net`

The server is writing a packet to the network.

8.14.4 Replication Source Thread States

The following list shows the most common states you may see in the `State` column for the `Binlog Dump` thread of the replication source. If you see no `Binlog Dump` threads on a source, this means that replication is not running; that is, that no replicas are currently connected.

- `Finished reading one binlog; switching to next binlog`

The thread has finished reading a binary log file and is opening the next one to send to the replica.

- `Master has sent all binlog to slave; waiting for more updates`

The thread has read all remaining updates from the binary logs and sent them to the replica. The thread is now idle, waiting for new events to appear in the binary log resulting from new updates occurring on the source.

- `Sending binlog event to slave`

Binary logs consist of *events*, where an event is usually an update plus some other information. The thread has read an event from the binary log and is now sending it to the replica.

- `Waiting to finalize termination`

A very brief state that occurs as the thread is stopping.

8.14.5 Replication I/O Thread States

The following list shows the most common states you see in the `State` column for a replication I/O thread on a replica server. This state also appears in the `Slave_IO_State` column displayed by `SHOW SLAVE STATUS`, so you can get a good view of what is happening by using that statement.

- `Checking master version`

A state that occurs very briefly, after the connection to the source is established.

- `Connecting to master`

The thread is attempting to connect to the source.

- `Queueing master event to the relay log`

The thread has read an event and is copying it to the relay log so that the SQL thread can process it.

- `Reconnecting after a failed binlog dump request`

The thread is trying to reconnect to the source.

- `Reconnecting after a failed master event read`

The thread is trying to reconnect to the source. When connection is established again, the state becomes `Waiting for master to send event`.

- `Registering slave on master`

A state that occurs very briefly after the connection to the source is established.

- `Requesting binlog dump`

A state that occurs very briefly, after the connection to the source is established. The thread sends to the source a request for the contents of its binary logs, starting from the requested binary log file name and position.

- `Waiting for its turn to commit`

A state that occurs when the replica thread is waiting for older worker threads to commit if `slave_preserve_commit_order` is enabled.

- `Waiting for master to send event`

The thread has connected to the source and is waiting for binary log events to arrive. This can last for a long time if the source is idle. If the wait lasts for `slave_net_timeout` seconds, a timeout occurs. At that point, the thread considers the connection to be broken and makes an attempt to reconnect.

- `Waiting for master update`

The initial state before `Connecting to master`.

- `Waiting for slave mutex on exit`

A state that occurs briefly as the thread is stopping.

- `Waiting for the slave SQL thread to free enough relay log space`

You are using a nonzero `relay_log_space_limit` value, and the relay logs have grown large enough that their combined size exceeds this value. The I/O thread is waiting until the SQL thread frees enough space by processing relay log contents so that it can delete some relay log files.

- `Waiting to reconnect after a failed binlog dump request`

If the binary log dump request failed (due to disconnection), the thread goes into this state while it sleeps, then tries to reconnect periodically. The interval between retries can be specified using the `CHANGE MASTER TO` statement.

- `Waiting to reconnect after a failed master event read`

An error occurred while reading (due to disconnection). The thread is sleeping for the number of seconds set by the `CHANGE MASTER TO` statement (default 60) before attempting to reconnect.

8.14.6 Replication SQL Thread States

The following list shows the most common states you may see in the `State` column for a replication SQL thread on a replica server:

- `Making temporary file (append) before replaying LOAD DATA INFILE`

The thread is executing a `LOAD DATA` statement and is appending the data to a temporary file containing the data from which the replica will read rows.

- `Making temporary file (create) before replaying LOAD DATA INFILE`

The thread is executing a `LOAD DATA` statement and is creating a temporary file containing the data from which the replica will read rows. This state can only be encountered if the original `LOAD DATA` statement was logged by a source running a version of MySQL lower than MySQL 5.0.3.

- `Reading event from the relay log`

The thread has read an event from the relay log so that the event can be processed.

- `Slave has read all relay log; waiting for more updates`

The thread has processed all events in the relay log files, and is now waiting for the I/O thread to write new events to the relay log.

- `Waiting for an event from Coordinator`

Using the multithreaded replica (`slave_parallel_workers` is greater than 1), one of the replica worker threads is waiting for an event from the coordinator thread.

- `Waiting for slave mutex on exit`

A very brief state that occurs as the thread is stopping.

- `Waiting for Slave Workers to free pending events`

This waiting action occurs when the total size of events being processed by Workers exceeds the size of the `slave_pending_jobs_size_max` system variable. The Coordinator resumes scheduling when the size drops below this limit. This state occurs only when `slave_parallel_workers` is set greater than 0.

- `Waiting for the next event in relay log`

The initial state before `Reading event from the relay log`.

- `Waiting until MASTER_DELAY seconds after master executed event`

The SQL thread has read an event but is waiting for the replica delay to lapse. This delay is set with the `MASTER_DELAY` option of `CHANGE MASTER TO`.

The `Info` column for the SQL thread may also show the text of a statement. This indicates that the thread has read an event from the relay log, extracted the statement from it, and may be executing it.

8.14.7 Replication Connection Thread States

These thread states occur on a replica server but are associated with connection threads, not with the I/O or SQL threads.

- `Changing master`

The thread is processing a `CHANGE MASTER TO` statement.

- `Killing slave`

The thread is processing a `STOP SLAVE` statement.

- `Opening master dump table`

This state occurs after `Creating table from master dump`.

- `Reading master dump table data`

This state occurs after `Opening master dump table`.

- `Rebuilding the index on master dump table`

This state occurs after `Reading master dump table data`.

8.14.8 NDB Cluster Thread States

- `Committing events to binlog`
- `Opening mysql.ndb_apply_status`

- `Processing events`

The thread is processing events for binary logging.

- `Processing events from schema table`

The thread is doing the work of schema replication.

- `Shutting down`

- `Syncing ndb table schema operation and binlog`

This is used to have a correct binary log of schema operations for NDB.

- `Waiting for allowed to take ndbcluster global schema lock`

The thread is waiting for permission to take a global schema lock.

- `Waiting for event from ndbcluster`

The server is acting as an SQL node in an NDB Cluster, and is connected to a cluster management node.

- `Waiting for first event from ndbcluster`

- `Waiting for ndbcluster binlog update to reach current position`

- `Waiting for ndbcluster global schema lock`

The thread is waiting for a global schema lock held by another thread to be released.

- `Waiting for ndbcluster to start`

- `Waiting for schema epoch`

The thread is waiting for a schema epoch (that is, a global checkpoint).

8.14.9 Event Scheduler Thread States

These states occur for the Event Scheduler thread, threads that are created to execute scheduled events, or threads that terminate the scheduler.

- `Clearing`

The scheduler thread or a thread that was executing an event is terminating and is about to end.

- `Initialized`

The scheduler thread or a thread that will execute an event has been initialized.

- `Waiting for next activation`

The scheduler has a nonempty event queue but the next activation is in the future.

- `Waiting for scheduler to stop`

The thread issued `SET GLOBAL event_scheduler=OFF` and is waiting for the scheduler to stop.

- `Waiting on empty queue`

The scheduler's event queue is empty and it is sleeping.

Chapter 9 Language Structure

Table of Contents

9.1 Literal Values	1647
9.1.1 String Literals	1647
9.1.2 Numeric Literals	1650
9.1.3 Date and Time Literals	1650
9.1.4 Hexadecimal Literals	1652
9.1.5 Bit-Value Literals	1654
9.1.6 Boolean Literals	1656
9.1.7 NULL Values	1656
9.2 Schema Object Names	1656
9.2.1 Identifier Length Limits	1658
9.2.2 Identifier Qualifiers	1659
9.2.3 Identifier Case Sensitivity	1660
9.2.4 Mapping of Identifiers to File Names	1662
9.2.5 Function Name Parsing and Resolution	1663
9.3 Keywords and Reserved Words	1667
9.4 User-Defined Variables	1694
9.5 Expressions	1697
9.6 Comment Syntax	1701

This chapter discusses the rules for writing the following elements of [SQL](#) statements when using MySQL:

- Literal values such as strings and numbers
- Identifiers such as database, table, and column names
- Keywords and reserved words
- User-defined and system variables
- Comments

9.1 Literal Values

This section describes how to write literal values in MySQL. These include strings, numbers, hexadecimal and bit values, boolean values, and [NULL](#). The section also covers various nuances that you may encounter when dealing with these basic types in MySQL.

9.1.1 String Literals

A string is a sequence of bytes or characters, enclosed within either single quote (`'`) or double quote (`"`) characters. Examples:

```
'a string'
"another string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
```

If the [ANSI_QUOTES](#) SQL mode is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

A *binary string* is a string of bytes. Every binary string has a character set and collation named `binary`. A *nonbinary string* is a string of characters. It has a character set other than `binary` and a collation that is compatible with the character set.

For both types of strings, comparisons are based on the numeric values of the string unit. For binary strings, the unit is the byte; comparisons use numeric byte values. For nonbinary strings, the unit is the character and some character sets support multibyte characters; comparisons use numeric character code values. Character code ordering is a function of the string collation. (For more information, see [Section 10.8.5, “The binary Collation Compared to `_bin` Collations”](#).)

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1'string';
SELECT _binary'string';
SELECT _utf8'string' COLLATE utf8_danish_ci;
```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

For information about these forms of string syntax, see [Section 10.3.7, “The National Character Set”](#), and [Section 10.3.8, “Character Set Introducers”](#).

Within a string, certain sequences have special meaning unless the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in [Table 9.1, “Special Character Escape Sequences”](#). For all other escape sequences, backslash is ignored. That is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These sequences are case-sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`. Escape processing is done according to the character set indicated by the `character_set_connection` system variable. This is true even for strings that are preceded by an introducer that indicates a different character set, as discussed in [Section 10.3.6, “Character String Literal Character Set and Collation”](#).

Table 9.1 Special Character Escape Sequences

Escape Sequence	Character Represented by Sequence
<code>\0</code>	An ASCII NUL (<code>x'00'</code>) character
<code>\'</code>	A single quote (<code>'</code>) character
<code>\"</code>	A double quote (<code>"</code>) character
<code>\b</code>	A backspace character
<code>\n</code>	A newline (linefeed) character
<code>\r</code>	A carriage return character
<code>\t</code>	A tab character
<code>\z</code>	ASCII 26 (Control+Z); see note following the table
<code>\\</code>	A backslash (<code>\</code>) character
<code>\%</code>	A <code>%</code> character; see note following the table
<code>_</code>	A <code>_</code> character; see note following the table

The ASCII 26 character can be encoded as `\Z` to enable you to work around the problem that ASCII 26 stands for END-OF-FILE on Windows. ASCII 26 within a file causes problems if you try to use `mysql db_name < file_name`.

The `\%` and `_` sequences are used to search for literal instances of `%` and `_` in pattern-matching contexts where they would otherwise be interpreted as wildcard characters. See the description of the `LIKE` operator in [Section 12.8.1, “String Comparison Functions and Operators”](#). If you use `\%` or `_` outside of pattern-matching contexts, they evaluate to the strings `\%` and `_`, not to `%` and `_`.

There are several ways to include quote characters within a string:

- A `'` inside a string quoted with `'` may be written as `''`.
- A `"` inside a string quoted with `"` may be written as `""`.
- Precede the quote character by an escape character (`\`).
- A `'` inside a string quoted with `"` needs no special treatment and need not be doubled or escaped. In the same way, `"` inside a string quoted with `'` needs no special treatment.

The following `SELECT` statements demonstrate how quoting and escaping work:

```
mysql> SELECT 'hello', '"hello"', '"hello"', 'hel'lo', '\hello';
+-----+-----+-----+-----+-----+
| hello | "hello" | "hello" | hel'lo | \hello |
+-----+-----+-----+-----+-----+

mysql> SELECT "hello", "'hello'", "'hello'", "hel"lo", "\"hello";
+-----+-----+-----+-----+-----+
| hello | 'hello' | 'hello' | hel"lo | "\"hello |
+-----+-----+-----+-----+-----+

mysql> SELECT 'This\nIs\nFour\nLines';
+-----+
| This
Is
Four
Lines |
+-----+

mysql> SELECT 'disappearing\ backslash';
+-----+
| disappearing backslash |
+-----+
```

To insert binary data into a string column (such as a `BLOB` column), you should represent certain characters by escape sequences. Backslash (`\`) and the quote character used to quote the string must be escaped. In certain client environments, it may also be necessary to escape `NUL` or Control+Z. The `mysql` client truncates quoted strings containing `NUL` characters if they are not escaped, and Control+Z may be taken for END-OF-FILE on Windows if not escaped. For the escape sequences that represent each of these characters, see [Table 9.1, “Special Character Escape Sequences”](#).

When writing application programs, any string that might contain any of these special characters must be properly escaped before the string is used as a data value in an SQL statement that is sent to the MySQL server. You can do this in two ways:

- Process the string with a function that escapes the special characters. In a C program, you can use the `mysql_real_escape_string_quote()` C API function to escape characters. See [mysql_real_escape_string_quote\(\)](#). Within SQL statements that construct other SQL statements, you can use the `QUOTE()` function. The Perl DBI interface provides a `quote` method to convert special characters to the proper escape sequences. See [Section 28.9, “MySQL Perl API”](#). Other language interfaces may provide a similar capability.
- As an alternative to explicitly escaping special characters, many MySQL APIs provide a placeholder capability that enables you to insert special markers into a statement string, and then bind data

values to them when you issue the statement. In this case, the API takes care of escaping special characters in the values for you.

9.1.2 Numeric Literals

Number literals include exact-value (integer and [DECIMAL](#)) literals and approximate-value (floating-point) literals.

Integers are represented as a sequence of digits. Numbers may include `.` as a decimal separator. Numbers may be preceded by `-` or `+` to indicate a negative or positive value, respectively. Numbers represented in scientific notation with a mantissa and exponent are approximate-value numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The [DECIMAL](#) data type is a fixed-point type and calculations are exact. In MySQL, the [DECIMAL](#) type has several synonyms: [NUMERIC](#), [DEC](#), [FIXED](#). The integer types also are exact-value types. For more information about exact-value calculations, see [Section 12.25, "Precision Math"](#).

The [FLOAT](#) and [DOUBLE](#) data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with [FLOAT](#) or [DOUBLE](#) are [DOUBLE PRECISION](#) and [REAL](#).

An integer may be used in floating-point context; it is interpreted as the equivalent floating-point number.

9.1.3 Date and Time Literals

Date and time values can be represented in several formats, such as quoted strings or as numbers, depending on the exact type of the value and other factors. For example, in contexts where MySQL expects a date, it interprets any of `'2015-07-21'`, `'20150721'`, and `20150721` as a date.

This section describes the acceptable formats for date and time literals. For more information about the temporal data types, such as the range of permitted values, see [Section 11.2, "Date and Time Data Types"](#).

Standard SQL and ODBC Date and Time Literals. Standard SQL requires temporal literals to be specified using a type keyword and a string. The space between the keyword and string is optional.

```
DATE 'str'
TIME 'str'
TIMESTAMP 'str'
```

MySQL recognizes but, unlike standard SQL, does not require the type keyword. Applications that are to be standard-compliant should include the type keyword for temporal literals.

MySQL also recognizes the ODBC syntax corresponding to the standard SQL syntax:

```
{ d 'str' }
{ t 'str' }
{ ts 'str' }
```

MySQL uses the type keywords and the ODBC constructions to produce [DATE](#), [TIME](#), and [DATETIME](#) values, respectively, including a trailing fractional seconds part if specified. The [TIMESTAMP](#) syntax produces a [DATETIME](#) value in MySQL because [DATETIME](#) has a range that more closely corresponds

to the standard SQL `TIMESTAMP` type, which has a year range from 0001 to 9999. (The MySQL `TIMESTAMP` year range is 1970 to 2038.)

String and Numeric Literals in Date and Time Context. MySQL recognizes `DATE` values in these formats:

- As a string in either `'YYYY-MM-DD'` or `'YY-MM-DD'` format. A “relaxed” syntax is permitted: Any punctuation character may be used as the delimiter between date parts. For example, `'2012-12-31'`, `'2012/12/31'`, `'2012^12^31'`, and `'2012@12@31'` are equivalent.
- As a string with no delimiters in either `'YYYYMMDD'` or `'YYMMDD'` format, provided that the string makes sense as a date. For example, `'20070523'` and `'070523'` are interpreted as `'2007-05-23'`, but `'071332'` is illegal (it has nonsensical month and day parts) and becomes `'0000-00-00'`.
- As a number in either `YYYYMMDD` or `YYMMDD` format, provided that the number makes sense as a date. For example, 19830905 and 830905 are interpreted as `'1983-09-05'`.

MySQL recognizes `DATETIME` and `TIMESTAMP` values in these formats:

- As a string in either `'YYYY-MM-DD hh:mm:ss'` or `'YY-MM-DD hh:mm:ss'` format. A “relaxed” syntax is permitted here, too: Any punctuation character may be used as the delimiter between date parts or time parts. For example, `'2012-12-31 11:30:45'`, `'2012^12^31 11+30+45'`, `'2012/12/31 11*30*45'`, and `'2012@12@31 11^30^45'` are equivalent.

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

The date and time parts can be separated by `T` rather than a space. For example, `'2012-12-31 11:30:45'` and `'2012-12-31T11:30:45'` are equivalent.

- As a string with no delimiters in either `'YYYYMMDDhhmmss'` or `'YYMMDDhhmmss'` format, provided that the string makes sense as a date. For example, `'20070523091528'` and `'070523091528'` are interpreted as `'2007-05-23 09:15:28'`, but `'071122129015'` is illegal (it has a nonsensical minute part) and becomes `'0000-00-00 00:00:00'`.
- As a number in either `YYYYMMDDhhmmss` or `YYMMDDhhmmss` format, provided that the number makes sense as a date. For example, 19830905132800 and 830905132800 are interpreted as `'1983-09-05 13:28:00'`.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see [Section 11.2.6, “Fractional Seconds in Time Values”](#).

Dates containing two-digit year values are ambiguous because the century is unknown. MySQL interprets two-digit year values using these rules:

- Year values in the range 70–99 become 1970–1999.
- Year values in the range 00–69 become 2000–2069.

See also [Section 11.2.8, “2-Digit Years in Dates”](#).

For values specified as strings that include date part delimiters, it is unnecessary to specify two digits for month or day values that are less than 10. `'2015-6-9'` is the same as `'2015-06-09'`. Similarly, for values specified as strings that include time part delimiters, it is unnecessary to specify two digits for hour, minute, or second values that are less than 10. `'2015-10-30 1:2:3'` is the same as `'2015-10-30 01:02:03'`.

Values specified as numbers should be 6, 8, 12, or 14 digits long. If a number is 8 or 14 digits long, it is assumed to be in `YYYYMMDD` or `YYYYMMDDhhmmss` format and that the year is given by the first 4

digits. If the number is 6 or 12 digits long, it is assumed to be in `YYMMDD` or `YYMMDDhhmmss` format and that the year is given by the first 2 digits. Numbers that are not one of these lengths are interpreted as though padded with leading zeros to the closest length.

Values specified as nondelimited strings are interpreted according to their length. For a string 8 or 14 characters long, the year is assumed to be given by the first 4 characters. Otherwise, the year is assumed to be given by the first 2 characters. The string is interpreted from left to right to find year, month, day, hour, minute, and second values, for as many parts as are present in the string. This means you should not use strings that have fewer than 6 characters. For example, if you specify `'9903'`, thinking that represents March, 1999, MySQL converts it to the “zero” date value. This occurs because the year and month values are `99` and `03`, but the day part is completely missing. However, you can explicitly specify a value of zero to represent missing month or day parts. For example, to insert the value `'1999-03-00'`, use `'990300'`.

MySQL recognizes `TIME` values in these formats:

- As a string in `'D hh:mm:ss'` format. You can also use one of the following “relaxed” syntaxes: `'hh:mm:ss'`, `'hh:mm'`, `'D hh:mm'`, `'D hh'`, or `'ss'`. Here `D` represents days and can have a value from 0 to 34.
- As a string with no delimiters in `'hhmmss'` format, provided that it makes sense as a time. For example, `'101112'` is understood as `'10:11:12'`, but `'109712'` is illegal (it has a nonsensical minute part) and becomes `'00:00:00'`.
- As a number in `hhmmss` format, provided that it makes sense as a time. For example, `101112` is understood as `'10:11:12'`. The following alternative formats are also understood: `ss`, `mmss`, or `hhmmss`.

A trailing fractional seconds part is recognized in the `'D hh:mm:ss.fraction'`, `'hh:mm:ss.fraction'`, `'hhmmss.fraction'`, and `hhmmss.fraction` time formats, where `fraction` is the fractional part in up to microseconds (6 digits) precision. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see [Section 11.2.6, “Fractional Seconds in Time Values”](#).

For `TIME` values specified as strings that include a time part delimiter, it is unnecessary to specify two digits for hours, minutes, or seconds values that are less than 10. `'8:3:2'` is the same as `'08:03:02'`.

9.1.4 Hexadecimal Literals

Hexadecimal literal values are written using `X'val'` or `0xval` notation, where `val` contains hexadecimal digits (`0..9, A..F`). Lettercase of the digits and of any leading `x` does not matter. A leading `0x` is case-sensitive and cannot be written as `0X`.

Legal hexadecimal literals:

```
X'01AF'
X'01af'
x'01AF'
x'01af'
0x01AF
0x01af
```

Illegal hexadecimal literals:

```
X'0G'    (G is not a hexadecimal digit)
0X01AF   (0X must be written as 0x)
```

Values written using `X'val'` notation must contain an even number of digits or a syntax error occurs. To correct the problem, pad the value with a leading zero:

```
mysql> SET @s = X'FFF';
ERROR 1064 (42000): You have an error in your SQL syntax;
check the manual that corresponds to your MySQL server
version for the right syntax to use near 'X'FFF''

mysql> SET @s = X'0FFF';
Query OK, 0 rows affected (0.00 sec)
```

Values written using `0xval` notation that contain an odd number of digits are treated as having an extra leading 0. For example, `0xaaa` is interpreted as `0x0aaa`.

By default, a hexadecimal literal is a binary string, where each pair of hexadecimal digits represents a character:

```
mysql> SELECT X'4D7953514C', CHARSET(X'4D7953514C');
+-----+-----+
| X'4D7953514C' | CHARSET(X'4D7953514C') |
+-----+-----+
| MySQL         | binary                  |
+-----+-----+
mysql> SELECT 0x5461626c65, CHARSET(0x5461626c65);
+-----+-----+
| 0x5461626c65 | CHARSET(0x5461626c65) |
+-----+-----+
| Table        | binary                  |
+-----+-----+
```

A hexadecimal literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] X'val' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1 X'4D7953514C';
SELECT _utf8 0x4D7953514C COLLATE utf8_danish_ci;
```

The examples use `X'val'` notation, but `0xval` notation permits introducers as well. For information about introducers, see [Section 10.3.8, “Character Set Introducers”](#).

In numeric contexts, MySQL treats a hexadecimal literal like a `BIGINT` (64-bit integer). To ensure numeric treatment of a hexadecimal literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a hexadecimal literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1  | @v2  | @v3  |
+-----+-----+-----+
| A    | 65   | 65   |
+-----+-----+-----+
```

An empty hexadecimal value (`X''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(X''), LENGTH(X'');
+-----+-----+
| CHARSET(X'') | LENGTH(X'') |
+-----+-----+
| binary      | 0           |
+-----+-----+
mysql> SELECT X''+0;
+-----+
| X''+0      |
+-----+
```

```
| 0 |
+-----+
```

The `X'val'` notation is based on standard SQL. The `0x` notation is based on ODBC, for which hexadecimal strings are often used to supply values for `BLOB` columns.

To convert a string or a number to a string in hexadecimal format, use the `HEX()` function:

```
mysql> SELECT HEX('cat');
+-----+
| HEX('cat') |
+-----+
| 636174      |
+-----+
mysql> SELECT X'636174';
+-----+
| X'636174'   |
+-----+
| cat          |
+-----+
```

For hexadecimal literals, bit operations are considered numeric context, but bit operations permit numeric or binary string arguments in MySQL 8.0 and higher. To explicitly specify binary string context for hexadecimal literals, use a `_binary` introducer for at least one of the arguments:

```
mysql> SET @v1 = X'000D' | X'0BC0';
mysql> SET @v2 = _binary X'000D' | X'0BC0';
mysql> SELECT HEX(@v1), HEX(@v2);
+-----+-----+
| HEX(@v1) | HEX(@v2) |
+-----+-----+
| BCD      | 0BCD     |
+-----+-----+
```

The displayed result appears similar for both bit operations, but the result without `_binary` is a `BIGINT` value, whereas the result with `_binary` is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

9.1.5 Bit-Value Literals

Bit-value literals are written using `b'val'` or `0bval` notation. `val` is a binary value written using zeros and ones. Lettercase of any leading `b` does not matter. A leading `0b` is case sensitive and cannot be written as `0B`.

Legal bit-value literals:

```
b'01'
B'01'
0b01
```

Illegal bit-value literals:

```
b'2'      (2 is not a binary digit)
0B01      (0B must be written as 0b)
```

By default, a bit-value literal is a binary string:

```
mysql> SELECT b'1000001', CHARSET(b'1000001');
+-----+-----+
| b'1000001' | CHARSET(b'1000001') |
+-----+-----+
| A          | binary               |
+-----+-----+
mysql> SELECT 0b1100001, CHARSET(0b1100001);
+-----+-----+
| 0b1100001 | CHARSET(0b1100001) |
+-----+-----+
```

```
+-----+-----+
| a      | binary      |
+-----+-----+
```

A bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] b'val' [COLLATE collation_name]
```

Examples:

```
SELECT _latin1 b'1000001';
SELECT _utf8 0b1000001 COLLATE utf8_danish_ci;
```

The examples use `b'val'` notation, but `0bval` notation permits introducers as well. For information about introducers, see [Section 10.3.8, “Character Set Introducers”](#).

In numeric contexts, MySQL treats a bit literal like an integer. To ensure numeric treatment of a bit literal, use it in numeric context. Ways to do this include adding 0 or using `CAST(... AS UNSIGNED)`. For example, a bit literal assigned to a user-defined variable is a binary string by default. To assign the value as a number, use it in numeric context:

```
mysql> SET @v1 = b'1100001';
mysql> SET @v2 = b'1100001'+0;
mysql> SET @v3 = CAST(b'1100001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1  | @v2  | @v3  |
+-----+-----+-----+
| a    | 97   | 97   |
+-----+-----+-----+
```

An empty bit value (`b''`) evaluates to a zero-length binary string. Converted to a number, it produces 0:

```
mysql> SELECT CHARSET(b''), LENGTH(b'');
+-----+-----+
| CHARSET(b'') | LENGTH(b'') |
+-----+-----+
| binary      | 0           |
+-----+-----+
mysql> SELECT b''+0;
+-----+
| b''+0 |
+-----+
| 0     |
+-----+
```

Bit-value notation is convenient for specifying values to be assigned to `BIT` columns:

```
mysql> CREATE TABLE t (b BIT(8));
mysql> INSERT INTO t SET b = b'11111111';
mysql> INSERT INTO t SET b = b'1010';
mysql> INSERT INTO t SET b = b'0101';
```

Bit values in result sets are returned as binary values, which may not display well. To convert a bit value to printable form, use it in numeric context or use a conversion function such as `BIN()` or `HEX()`. High-order 0 digits are not displayed in the converted value.

```
mysql> SELECT b+0, BIN(b), OCT(b), HEX(b) FROM t;
+-----+-----+-----+-----+
| b+0  | BIN(b) | OCT(b) | HEX(b) |
+-----+-----+-----+-----+
| 255  | 11111111 | 377    | FF     |
| 10   | 1010    | 12     | A      |
| 5    | 101     | 5      | 5      |
+-----+-----+-----+-----+
```

```
+-----+-----+-----+-----+
```

For bit literals, bit operations are considered numeric context, but bit operations permit numeric or binary string arguments in MySQL 8.0 and higher. To explicitly specify binary string context for bit literals, use a `_binary` introducer for at least one of the arguments:

```
mysql> SET @v1 = b'000010101' | b'000101010';
mysql> SET @v2 = _binary b'000010101' | _binary b'000101010';
mysql> SELECT HEX(@v1), HEX(@v2);
```

HEX(@v1)	HEX(@v2)
3F	003F

The displayed result appears similar for both bit operations, but the result without `_binary` is a `BIGINT` value, whereas the result with `_binary` is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

9.1.6 Boolean Literals

The constants `TRUE` and `FALSE` evaluate to `1` and `0`, respectively. The constant names can be written in any lettercase.

```
mysql> SELECT TRUE, true, FALSE, false;
-> 1, 1, 0, 0
```

9.1.7 NULL Values

The `NULL` value means “no data.” `NULL` can be written in any lettercase.

Be aware that the `NULL` value is different from values such as `0` for numeric types or the empty string for string types. For more information, see [Section B.3.4.3, “Problems with NULL Values”](#).

For text file import or export operations performed with `LOAD DATA` or `SELECT ... INTO OUTFILE`, `NULL` is represented by the `\N` sequence. See [Section 13.2.7, “LOAD DATA Statement”](#).

For sorting with `ORDER BY`, `NULL` values sort before other values for ascending sorts, after other values for descending sorts.

9.2 Schema Object Names

Certain objects within MySQL, including database, table, index, column, alias, view, stored procedure, partition, tablespace, resource group and other object names are known as identifiers. This section describes the permissible syntax for identifiers in MySQL. [Section 9.2.1, “Identifier Length Limits”](#), indicates the maximum length of each type of identifier. [Section 9.2.3, “Identifier Case Sensitivity”](#), describes which types of identifiers are case-sensitive and under what conditions.

An identifier may be quoted or unquoted. If an identifier contains special characters or is a reserved word, you *must* quote it whenever you refer to it. (Exception: A reserved word that follows a period in a qualified name must be an identifier, so it need not be quoted.) Reserved words are listed at [Section 9.3, “Keywords and Reserved Words”](#).

Internally, identifiers are converted to and are stored as Unicode (UTF-8). The permissible Unicode characters in identifiers are those in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted. Identifiers thus may contain these characters:

- Permitted characters in unquoted identifiers:
 - ASCII: [0-9,a-z,A-Z\$_] (basic Latin letters, digits 0-9, dollar, underscore)

- Extended: U+0080 .. U+FFFF
- Permitted characters in quoted identifiers include the full Unicode Basic Multilingual Plane (BMP), except U+0000:
 - ASCII: U+0001 .. U+007F
 - Extended: U+0080 .. U+FFFF
- ASCII NUL (U+0000) and supplementary characters (U+10000 and higher) are not permitted in quoted or unquoted identifiers.
- Identifiers may begin with a digit but unless quoted may not consist solely of digits.
- Database, table, and column names cannot end with space characters.

The identifier quote character is the backtick (`):

```
mysql> SELECT * FROM `select` WHERE `select`.id > 100;
```

If the [ANSI_QUOTES](#) SQL mode is enabled, it is also permissible to quote identifiers within double quotation marks:

```
mysql> CREATE TABLE "test" (col INT);
ERROR 1064: You have an error in your SQL syntax...
mysql> SET sql_mode='ANSI_QUOTES';
mysql> CREATE TABLE "test" (col INT);
Query OK, 0 rows affected (0.00 sec)
```

The [ANSI_QUOTES](#) mode causes the server to interpret double-quoted strings as identifiers. Consequently, when this mode is enabled, string literals must be enclosed within single quotation marks. They cannot be enclosed within double quotation marks. The server SQL mode is controlled as described in [Section 5.1.11, “Server SQL Modes”](#).

Identifier quote characters can be included within an identifier if you quote the identifier. If the character to be included within the identifier is the same as that used to quote the identifier itself, then you need to double the character. The following statement creates a table named `a`b` that contains a column named `c"d`:

```
mysql> CREATE TABLE `a``b` (`c"d` INT);
```

In the select list of a query, a quoted column alias can be specified using identifier or string quoting characters:

```
mysql> SELECT 1 AS `one`, 2 AS 'two';
+-----+-----+
| one | two |
+-----+-----+
| 1 | 2 |
+-----+-----+
```

Elsewhere in the statement, quoted references to the alias must use identifier quoting or the reference is treated as a string literal.

It is recommended that you do not use names that begin with `Me` or `MeN`, where `M` and `N` are integers. For example, avoid using `1e` as an identifier, because an expression such as `1e+3` is ambiguous. Depending on context, it might be interpreted as the expression `1e + 3` or as the number `1e+3`.

Be careful when using `MD5()` to produce table names because it can produce names in illegal or ambiguous formats such as those just described.

A user variable cannot be used directly in an SQL statement as an identifier or as part of an identifier. See [Section 9.4, “User-Defined Variables”](#), for more information and examples of workarounds.

Special characters in database and table names are encoded in the corresponding file system names as described in [Section 9.2.4, “Mapping of Identifiers to File Names”](#).

9.2.1 Identifier Length Limits

The following table describes the maximum length for each type of identifier.

Identifier Type	Maximum Length (characters)
Database	64 (includes NDB Cluster 8.0.18 and later)
Table	64 (includes NDB Cluster 8.0.18 and later)
Column	64
Index	64
Constraint	64
Stored Program	64
View	64
Tablespace	64
Server	64
Log File Group	64
Alias	256 (see exception following table)
Compound Statement Label	16
User-Defined Variable	64
Resource Group	64

Aliases for column names in `CREATE VIEW` statements are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

For constraint definitions that include no constraint name, the server internally generates a name derived from the associated table name. For example, internally generated foreign key and `CHECK` constraint names consist of the table name plus `_ibfk_` or `_chk_` and a number. If the table name is close to the length limit for constraint names, the additional characters required for the constraint name may cause that name to exceed the limit, resulting in an error.

Identifiers are stored using Unicode (UTF-8). This applies to identifiers in table definitions and to identifiers stored in the grant tables in the `mysql` database. The sizes of the identifier string columns in the grant tables are measured in characters. You can use multibyte characters without reducing the number of characters permitted for values stored in these columns.

Prior to NDB 8.0.18, NDB Cluster imposed a maximum length of 63 characters for names of databases and tables. As of NDB 8.0.18, this limitation is removed. See [Section 22.1.7.11, “Previous NDB Cluster Issues Resolved in NDB Cluster 8.0”](#).

Values such as user name and host names in MySQL account names are strings rather than identifiers. For information about the maximum length of such values as stored in grant tables, see [Grant Table Scope Column Properties](#).

9.2.2 Identifier Qualifiers

Object names may be unqualified or qualified. An unqualified name is permitted in contexts where interpretation of the name is unambiguous. A qualified name includes at least one qualifier to clarify the interpretive context by overriding a default context or providing missing context.

For example, this statement creates a table using the unqualified name `t1`:

```
CREATE TABLE t1 (i INT);
```

Because `t1` includes no qualifier to specify a database, the statement creates the table in the default database. If there is no default database, an error occurs.

This statement creates a table using the qualified name `db1.t1`:

```
CREATE TABLE db1.t1 (i INT);
```

Because `db1.t1` includes a database qualifier `db1`, the statement creates `t1` in the database named `db1`, regardless of the default database. The qualifier *must* be specified if there is no default database. The qualifier *may* be specified if there is a default database, to specify a database different from the default, or to make the database explicit if the default is the same as the one specified.

Qualifiers have these characteristics:

- An unqualified name consists of a single identifier. A qualified name consists of multiple identifiers.
- The components of a multiple-part name must be separated by period (.) characters. The initial parts of a multiple-part name act as qualifiers that affect the context within which to interpret the final identifier.
- The qualifier character is a separate token and need not be contiguous with the associated identifiers. For example, `tbl_name.col_name` and `tbl_name . col_name` are equivalent.
- If any components of a multiple-part name require quoting, quote them individually rather than quoting the name as a whole. For example, write ``my-table`.`my-column``, not ``my-table.my-column``.
- A reserved word that follows a period in a qualified name must be an identifier, so in that context it need not be quoted.

The permitted qualifiers for object names depend on the object type:

- A database name is fully qualified and takes no qualifier:

```
CREATE DATABASE db1;
```

- A table, view, or stored program name may be given a database-name qualifier. Examples of unqualified and qualified names in `CREATE` statements:

```
CREATE TABLE mytable ...;
CREATE VIEW myview ...;
CREATE PROCEDURE myproc ...;
CREATE FUNCTION myfunc ...;
CREATE EVENT myevent ...;

CREATE TABLE mydb.mytable ...;
```

```
CREATE VIEW mydb.myview ...;
CREATE PROCEDURE mydb.myproc ...;
CREATE FUNCTION mydb.myfunc ...;
CREATE EVENT mydb.myevent ...;
```

- A trigger is associated with a table, so any qualifier applies to the table name:

```
CREATE TRIGGER mytrigger ... ON mytable ...;

CREATE TRIGGER mytrigger ... ON mydb.mytable ...;
```

- A column name may be given multiple qualifiers to indicate context in statements that reference it, as shown in the following table.

Column Reference	Meaning
<i>col_name</i>	Column <i>col_name</i> from whichever table used in the statement contains a column of that name
<i>tbl_name.col_name</i>	Column <i>col_name</i> from table <i>tbl_name</i> of the default database
<i>db_name.tbl_name.col_name</i>	Column <i>col_name</i> from table <i>tbl_name</i> of the database <i>db_name</i>

In other words, a column name may be given a table-name qualifier, which itself may be given a database-name qualifier. Examples of unqualified and qualified column references in [SELECT](#) statements:

```
SELECT c1 FROM mytable
WHERE c2 > 100;

SELECT mytable.c1 FROM mytable
WHERE mytable.c2 > 100;

SELECT mydb.mytable.c1 FROM mydb.mytable
WHERE mydb.mytable.c2 > 100;
```

You need not specify a qualifier for an object reference in a statement unless the unqualified reference is ambiguous. Suppose that column *c1* occurs only in table *t1*, *c2* only in *t2*, and *c* in both *t1* and *t2*. Any unqualified reference to *c* is ambiguous in a statement that refers to both tables and must be qualified as *t1.c* or *t2.c* to indicate which table you mean:

```
SELECT c1, c2, t1.c FROM t1 INNER JOIN t2
WHERE t2.c > 100;
```

Similarly, to retrieve from a table *t* in database *db1* and from a table *t* in database *db2* in the same statement, you must qualify the table references: For references to columns in those tables, qualifiers are required only for column names that appear in both tables. Suppose that column *c1* occurs only in table *db1.t*, *c2* only in *db2.t*, and *c* in both *db1.t* and *db2.t*. In this case, *c* is ambiguous and must be qualified but *c1* and *c2* need not be:

```
SELECT c1, c2, db1.t.c FROM db1.t INNER JOIN db2.t
WHERE db2.t.c > 100;
```

Table aliases enable qualified column references to be written more simply:

```
SELECT c1, c2, t1.c FROM db1.t AS t1 INNER JOIN db2.t AS t2
WHERE t2.c > 100;
```

9.2.3 Identifier Case Sensitivity

In MySQL, databases correspond to directories within the data directory. Each table within a database corresponds to at least one file within the database directory (and possibly more, depending on the storage engine). Triggers also correspond to files. Consequently, the case sensitivity of the underlying operating system plays a part in the case sensitivity of database, table, and trigger names. This means

such names are not case-sensitive in Windows, but are case-sensitive in most varieties of Unix. One notable exception is macOS, which is Unix-based but uses a default file system type (HFS+) that is not case-sensitive. However, macOS also supports UFS volumes, which are case-sensitive just as on any Unix. See [Section 1.7.1, “MySQL Extensions to Standard SQL”](#). The `lower_case_table_names` system variable also affects how the server handles identifier case sensitivity, as described later in this section.

Note

Although database, table, and trigger names are not case sensitive on some platforms, you should not refer to one of these using different cases within the same statement. The following statement would not work because it refers to a table both as `my_table` and as `MY_TABLE`:

```
mysql> SELECT * FROM my_table WHERE MY_TABLE.col=1;
```

Partition, subpartition, column, index, stored routine, event, and resource group names are not case-sensitive on any platform, nor are column aliases.

However, names of logfile groups are case-sensitive. This differs from standard SQL.

By default, table aliases are case-sensitive on Unix, but not so on Windows or macOS. The following statement would not work on Unix, because it refers to the alias both as `a` and as `A`:

```
mysql> SELECT col_name FROM tbl_name AS a
       WHERE a.col_name = 1 OR A.col_name = 2;
```

However, this same statement is permitted on Windows. To avoid problems caused by such differences, it is best to adopt a consistent convention, such as always creating and referring to databases and tables using lowercase names. This convention is recommended for maximum portability and ease of use.

How table and database names are stored on disk and used in MySQL is affected by the `lower_case_table_names` system variable. `lower_case_table_names` can take the values shown in the following table. This variable does *not* affect case sensitivity of trigger identifiers. On Unix, the default value of `lower_case_table_names` is 0. On Windows, the default value is 1. On macOS, the default value is 2.

`lower_case_table_names` can only be configured when initializing the server. Changing the `lower_case_table_names` setting after the server is initialized is prohibited.

Value	Meaning
0	Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement. Name comparisons are case sensitive. You should <i>not</i> set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or macOS). If you force this variable to 0 with <code>--lower-case-table-names=0</code> on a case-insensitive file system and access <code>MyISAM</code> table names using different lettercases, index corruption may result.
1	Table names are stored in lowercase on disk and name comparisons are not case-sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.
2	Table and database names are stored on disk using the lettercase specified in the <code>CREATE TABLE</code> or <code>CREATE DATABASE</code> statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case sensitive. This works <i>only</i> on file systems that are not case-sensitive! <code>InnoDB</code> table names and view names are stored in lowercase, as for <code>lower_case_table_names=1</code> .

If you are using MySQL on only one platform, you do not normally have to use a `lower_case_table_names` setting other than the default. However, you may encounter difficulties if

you want to transfer tables between platforms that differ in file system case sensitivity. For example, on Unix, you can have two different tables named `my_table` and `MY_TABLE`, but on Windows these two names are considered identical. To avoid data transfer problems arising from lettercase of database or table names, you have two options:

- Use `lower_case_table_names=1` on all systems. The main disadvantage with this is that when you use `SHOW TABLES` or `SHOW DATABASES`, you do not see the names in their original lettercase.
- Use `lower_case_table_names=0` on Unix and `lower_case_table_names=2` on Windows. This preserves the lettercase of database and table names. The disadvantage of this is that you must ensure that your statements always refer to your database and table names with the correct lettercase on Windows. If you transfer your statements to Unix, where lettercase is significant, they do not work if the lettercase is incorrect.

Exception: If you are using InnoDB tables and you are trying to avoid these data transfer problems, you should use `lower_case_table_names=1` on all platforms to force names to be converted to lowercase.

Object names may be considered duplicates if their uppercase forms are equal according to a binary collation. That is true for names of cursors, conditions, procedures, functions, savepoints, stored routine parameters, stored program local variables, and plugins. It is not true for names of columns, constraints, databases, partitions, statements prepared with `PREPARE`, tables, triggers, users, and user-defined variables.

File system case sensitivity can affect searches in string columns of `INFORMATION_SCHEMA` tables. For more information, see [Section 10.8.7, “Using Collation in INFORMATION_SCHEMA Searches”](#).

9.2.4 Mapping of Identifiers to File Names

There is a correspondence between database and table identifiers and names in the file system. For the basic structure, MySQL represents each database as a directory in the data directory, and depending upon the storage engine, each table may be represented by one or more files in the appropriate database directory.

For the data and index files, the exact representation on disk is storage engine specific. These files may be stored in the database directory, or the information may be stored in a separate file. InnoDB data is stored in the InnoDB data files. If you are using tablespaces with InnoDB, then the specific tablespace files you create are used instead.

Any character is legal in database or table identifiers except ASCII NUL (`x'00'`). MySQL encodes any characters that are problematic in the corresponding file system objects when it creates database directories or table files:

- Basic Latin letters (`a..zA..Z`), digits (`0..9`) and underscore (`_`) are encoded as is. Consequently, their case sensitivity directly depends on file system features.
- All other national letters from alphabets that have uppercase/lowercase mapping are encoded as shown in the following table. Values in the Code Range column are UCS-2 values.

Code Range	Pattern	Number	Used	Unused	Blocks
00C0..017F	<code>[@][0..4][g..z]</code>	$5 \times 20 = 100$	97	3	Latin-1 Supplement + Latin Extended-A
0370..03FF	<code>[@][5..9][g..z]</code>	$5 \times 20 = 100$	88	12	Greek and Coptic
0400..052F	<code>[@][g..z][0..6]</code>	$20 \times 7 = 140$	137	3	Cyrillic + Cyrillic Supplement
0530..058F	<code>[@][g..z][7..8]</code>	$20 \times 2 = 40$	38	2	Armenian
2160..217F	<code>[@][g..z][9]</code>	$20 \times 1 = 20$	16	4	Number Forms

Code Range	Pattern	Number	Used	Unused	Blocks
0180..02AF	[@][g..z][a..k]	20*11=220	203	17	Latin Extended-B + IPA Extensions
1E00..1EFF	[@][g..z][l..r]	20*7= 140	136	4	Latin Extended Additional
1F00..1FFF	[@][g..z][s..z]	20*8= 160	144	16	Greek Extended
....	[@][a..f][g..z]	6*20= 120	0	120	RESERVED
24B6..24E9	[@][@][a..z]	26	26	0	Enclosed Alphanumerics
FF21..FF5A	[@][a..z][@]	26	26	0	Halfwidth and Fullwidth forms

One of the bytes in the sequence encodes lettercase. For example: [LATIN CAPITAL LETTER A WITH GRAVE](#) is encoded as @0G, whereas [LATIN SMALL LETTER A WITH GRAVE](#) is encoded as @0g. Here the third byte (G or g) indicates lettercase. (On a case-insensitive file system, both letters will be treated as the same.)

For some blocks, such as Cyrillic, the second byte determines lettercase. For other blocks, such as Latin1 Supplement, the third byte determines lettercase. If two bytes in the sequence are letters (as in Greek Extended), the leftmost letter character stands for lettercase. All other letter bytes must be in lowercase.

- All nonletter characters except underscore (`_`), as well as letters from alphabets that do not have uppercase/lowercase mapping (such as Hebrew) are encoded using hexadecimal representation using lowercase letters for hexadecimal digits `a..f`:

```
0x003F -> @003f
0xFFFF -> @ffff
```

The hexadecimal values correspond to character values in the [ucs2](#) double-byte character set.

On Windows, some names such as [nul](#), [prn](#), and [aux](#) are encoded by appending `@@@` to the name when the server creates the corresponding file or directory. This occurs on all platforms for portability of the corresponding database object between platforms.

9.2.5 Function Name Parsing and Resolution

MySQL supports built-in (native) functions, user-defined functions (UDFs), and stored functions. This section describes how the server recognizes whether the name of a built-in function is used as a function call or as an identifier, and how the server determines which function to use in cases when functions of different types exist with a given name.

- [Built-In Function Name Parsing](#)
- [Function Name Resolution](#)

Built-In Function Name Parsing

The parser uses default rules for parsing names of built-in functions. These rules can be changed by enabling the [IGNORE_SPACE](#) SQL mode.

When the parser encounters a word that is the name of a built-in function, it must determine whether the name signifies a function call or is instead a nonexpression reference to an identifier such as a table or column name. For example, in the following statements, the first reference to [count](#) is a function call, whereas the second reference is a table name:

```
SELECT COUNT(*) FROM mytable;
CREATE TABLE count (i INT);
```

The parser should recognize the name of a built-in function as indicating a function call only when parsing what is expected to be an expression. That is, in nonexpression context, function names are permitted as identifiers.

However, some built-in functions have special parsing or implementation considerations, so the parser uses the following rules by default to distinguish whether their names are being used as function calls or as identifiers in nonexpression context:

- To use the name as a function call in an expression, there must be no whitespace between the name and the following (parenthesis character.
- Conversely, to use the function name as an identifier, it must not be followed immediately by a parenthesis.

The requirement that function calls be written with no whitespace between the name and the parenthesis applies only to the built-in functions that have special considerations. `COUNT` is one such name. The `sql/lex.h` source file lists the names of these special functions for which following whitespace determines their interpretation: names defined by the `SYM_FN()` macro in the `symbols[]` array.

The following list names the functions in MySQL 8.0 that are affected by the `IGNORE_SPACE` setting and listed as special in the `sql/lex.h` source file. You may find it easiest to treat the no-whitespace requirement as applying to all function calls.

- `ADDDATE`
- `BIT_AND`
- `BIT_OR`
- `BIT_XOR`
- `CAST`
- `COUNT`
- `CURDATE`
- `CURTIME`
- `DATE_ADD`
- `DATE_SUB`
- `EXTRACT`
- `GROUP_CONCAT`
- `MAX`
- `MID`
- `MIN`
- `NOW`
- `POSITION`
- `SESSION_USER`
- `STD`
- `STDDEV`

- `STDDEV_POP`
- `STDDEV_SAMP`
- `SUBDATE`
- `SUBSTR`
- `SUBSTRING`
- `SUM`
- `SYSDATE`
- `SYSTEM_USER`
- `TRIM`
- `VARIANCE`
- `VAR_POP`
- `VAR_SAMP`

For functions not listed as special in `sql/lex.h`, whitespace does not matter. They are interpreted as function calls only when used in expression context and may be used freely as identifiers otherwise. `ASCII` is one such name. However, for these unaffected function names, interpretation may vary in expression context: `func_name ()` is interpreted as a built-in function if there is one with the given name; if not, `func_name ()` is interpreted as a user-defined function or stored function if one exists with that name.

The `IGNORE_SPACE` SQL mode can be used to modify how the parser treats function names that are whitespace-sensitive:

- With `IGNORE_SPACE` disabled, the parser interprets the name as a function call when there is no whitespace between the name and the following parenthesis. This occurs even when the function name is used in nonexpression context:

```
mysql> CREATE TABLE count(i INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'count(i INT)'
```

To eliminate the error and cause the name to be treated as an identifier, either use whitespace following the name or write it as a quoted identifier (or both):

```
CREATE TABLE count (i INT);
CREATE TABLE `count`(i INT);
CREATE TABLE `count` (i INT);
```

- With `IGNORE_SPACE` enabled, the parser loosens the requirement that there be no whitespace between the function name and the following parenthesis. This provides more flexibility in writing function calls. For example, either of the following function calls are legal:

```
SELECT COUNT(*) FROM mytable;
SELECT COUNT (*) FROM mytable;
```

However, enabling `IGNORE_SPACE` also has the side effect that the parser treats the affected function names as reserved words (see [Section 9.3, “Keywords and Reserved Words”](#)). This means that a space following the name no longer signifies its use as an identifier. The name can be used in function calls with or without following whitespace, but causes a syntax error in nonexpression context unless it is quoted. For example, with `IGNORE_SPACE` enabled, both of the following statements fail with a syntax error because the parser interprets `count` as a reserved word:

```
CREATE TABLE count(i INT);
```

```
CREATE TABLE count (i INT);
```

To use the function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count` (i INT);
CREATE TABLE `count` (i INT);
```

To enable the `IGNORE_SPACE` SQL mode, use this statement:

```
SET sql_mode = 'IGNORE_SPACE';
```

`IGNORE_SPACE` is also enabled by certain other composite modes such as `ANSI` that include it in their value:

```
SET sql_mode = 'ANSI';
```

Check [Section 5.1.11, “Server SQL Modes”](#), to see which composite modes enable `IGNORE_SPACE`.

To minimize the dependency of SQL code on the `IGNORE_SPACE` setting, use these guidelines:

- Avoid creating UDFs or stored functions that have the same name as a built-in function.
- Avoid using function names in nonexpression context. For example, these statements use `count` (one of the affected function names affected by `IGNORE_SPACE`), so they fail with or without whitespace following the name if `IGNORE_SPACE` is enabled:

```
CREATE TABLE count(i INT);
CREATE TABLE count (i INT);
```

If you must use a function name in nonexpression context, write it as a quoted identifier:

```
CREATE TABLE `count` (i INT);
CREATE TABLE `count` (i INT);
```

Function Name Resolution

The following rules describe how the server resolves references to function names for function creation and invocation:

- Built-in functions and user-defined functions

An error occurs if you try to create a UDF with the same name as a built-in function.

- Built-in functions and stored functions

It is possible to create a stored function with the same name as a built-in function, but to invoke the stored function it is necessary to qualify it with a schema name. For example, if you create a stored function named `PI` in the `test` schema, invoke it as `test.PI()` because the server resolves `PI()` without a qualifier as a reference to the built-in function. The server generates a warning if the stored function name collides with a built-in function name. The warning can be displayed with `SHOW WARNINGS`.

- User-defined functions and stored functions

User-defined functions and stored functions share the same namespace, so you cannot create a UDF and a stored function with the same name.

The preceding function name resolution rules have implications for upgrading to versions of MySQL that implement new built-in functions:

- If you have already created a user-defined function with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF and `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. Then modify any affected code to use the new name.

- If a new version of MySQL implements a built-in function with the same name as an existing stored function, you have two choices: Rename the stored function to use a nonconflicting name, or change calls to the function so that they use a schema qualifier (that is, use `schema_name.func_name()` syntax). In either case, modify any affected code accordingly.

9.3 Keywords and Reserved Words

Keywords are words that have significance in SQL. Certain keywords, such as `SELECT`, `DELETE`, or `BIGINT`, are reserved and require special treatment for use as identifiers such as table and column names. This may also be true for the names of built-in functions.

Nonreserved keywords are permitted as identifiers without quoting. Reserved words are permitted as identifiers if you quote them as described in [Section 9.2, “Schema Object Names”](#):

```
mysql> CREATE TABLE interval (begin INT, end INT);
ERROR 1064 (42000): You have an error in your SQL syntax ...
near 'interval (begin INT, end INT)'
```

`BEGIN` and `END` are keywords but not reserved, so their use as identifiers does not require quoting. `INTERVAL` is a reserved keyword and must be quoted to be used as an identifier:

```
mysql> CREATE TABLE `interval` (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Exception: A word that follows a period in a qualified name must be an identifier, so it need not be quoted even if it is reserved:

```
mysql> CREATE TABLE mydb.interval (begin INT, end INT);
Query OK, 0 rows affected (0.01 sec)
```

Names of built-in functions are permitted as identifiers but may require care to be used as such. For example, `COUNT` is acceptable as a column name. However, by default, no whitespace is permitted in function invocations between the function name and the following `(` character. This requirement enables the parser to distinguish whether the name is used in a function call or in nonfunction context. For further details on recognition of function names, see [Section 9.2.5, “Function Name Parsing and Resolution”](#).

The `INFORMATION_SCHEMA.KEYWORDS` table lists the words considered keywords by MySQL and indicates whether they are reserved. See [Section 25.18, “The INFORMATION_SCHEMA KEYWORDS Table”](#).

- [MySQL 8.0 Keywords and Reserved Words](#)
- [MySQL 8.0 New Keywords and Reserved Words](#)
- [MySQL 8.0 Removed Keywords and Reserved Words](#)

MySQL 8.0 Keywords and Reserved Words

The following list shows the keywords and reserved words in MySQL 8.0, along with changes to individual words from version to version. Reserved keywords are marked with (R). In addition, `_FILENAME` is reserved.

At some point, you might upgrade to a higher version, so it is a good idea to have a look at future reserved words, too. You can find these in the manuals that cover higher versions of MySQL. Most of the reserved words in the list are forbidden by standard SQL as column or table names (for example, `GROUP`). A few are reserved because MySQL needs them and uses a `yacc` parser.

A | B | C | D | E | F | G | H | I | J | K | L | M | N | O | P | Q | R | S | T | U | V | W | X | Y | Z

A

- `ACCESSIBLE` (R)
- `ACCOUNT`
- `ACTION`
- `ACTIVE`; added in 8.0.14 (nonreserved)
- `ADD` (R)
- `ADMIN`; became nonreserved in 8.0.12
- `AFTER`
- `AGAINST`
- `AGGREGATE`
- `ALGORITHM`
- `ALL` (R)
- `ALTER` (R)
- `ALWAYS`
- `ANALYSE`; removed in 8.0.1
- `ANALYZE` (R)
- `AND` (R)
- `ANY`
- `ARRAY`; added in 8.0.17 (reserved); became nonreserved in 8.0.19
- `AS` (R)
- `ASC` (R)
- `ASCII`
- `ASENSITIVE` (R)
- `AT`
- `ATTRIBUTE`; added in 8.0.21 (nonreserved)
- `AUTOEXTEND_SIZE`
- `AUTO_INCREMENT`
- `AVG`
- `AVG_ROW_LENGTH`

B

- `BACKUP`
- `BEFORE` (R)
- `BEGIN`
- `BETWEEN` (R)

- `BIGINT` (R)
- `BINARY` (R)
- `BINLOG`
- `BIT`
- `BLOB` (R)
- `BLOCK`
- `BOOL`
- `BOOLEAN`
- `BOTH` (R)
- `BTREE`
- `BUCKETS`; added in 8.0.2 (nonreserved)
- `BY` (R)
- `BYTE`

C

- `CACHE`
- `CALL` (R)
- `CASCADE` (R)
- `CASCADED`
- `CASE` (R)
- `CATALOG_NAME`
- `CHAIN`
- `CHANGE` (R)
- `CHANGED`
- `CHANNEL`
- `CHAR` (R)
- `CHARACTER` (R)
- `CHARSET`
- `CHECK` (R)
- `CHECKSUM`
- `CIPHER`
- `CLASS_ORIGIN`
- `CLIENT`
- `CLONE`; added in 8.0.3 (nonreserved)

- `CLOSE`
- `COALESCE`
- `CODE`
- `COLLATE (R)`
- `COLLATION`
- `COLUMN (R)`
- `COLUMNS`
- `COLUMN_FORMAT`
- `COLUMN_NAME`
- `COMMENT`
- `COMMIT`
- `COMMITTED`
- `COMPACT`
- `COMPLETION`
- `COMPONENT`
- `COMPRESSED`
- `COMPRESSION`
- `CONCURRENT`
- `CONDITION (R)`
- `CONNECTION`
- `CONSISTENT`
- `CONSTRAINT (R)`
- `CONSTRAINT_CATALOG`
- `CONSTRAINT_NAME`
- `CONSTRAINT_SCHEMA`
- `CONTAINS`
- `CONTEXT`
- `CONTINUE (R)`
- `CONVERT (R)`
- `CPU`
- `CREATE (R)`
- `CROSS (R)`
- `CUBE (R)`; became reserved in 8.0.1

- `CUME_DIST` (R); added in 8.0.2 (reserved)
- `CURRENT`
- `CURRENT_DATE` (R)
- `CURRENT_TIME` (R)
- `CURRENT_TIMESTAMP` (R)
- `CURRENT_USER` (R)
- `CURSOR` (R)
- `CURSOR_NAME`

D

- `DATA`
- `DATABASE` (R)
- `DATABASES` (R)
- `DATAFILE`
- `DATE`
- `DATETIME`
- `DAY`
- `DAY_HOUR` (R)
- `DAY_MICROSECOND` (R)
- `DAY_MINUTE` (R)
- `DAY_SECOND` (R)
- `DEALLOCATE`
- `DEC` (R)
- `DECIMAL` (R)
- `DECLARE` (R)
- `DEFAULT` (R)
- `DEFAULT_AUTH`
- `DEFINER`
- `DEFINITION`; added in 8.0.4 (nonreserved)
- `DELAYED` (R)
- `DELAY_KEY_WRITE`
- `DELETE` (R)
- `DENSE_RANK` (R); added in 8.0.2 (reserved)
- `DESC` (R)

- `DESCRIBE` (R)
- `DESCRIPTION`; added in 8.0.4 (nonreserved)
- `DES_KEY_FILE`; removed in 8.0.3
- `DETERMINISTIC` (R)
- `DIAGNOSTICS`
- `DIRECTORY`
- `DISABLE`
- `DISCARD`
- `DISK`
- `DISTINCT` (R)
- `DISTINCTROW` (R)
- `DIV` (R)
- `DO`
- `DOUBLE` (R)
- `DROP` (R)
- `DUAL` (R)
- `DUMPFIL`
- `DUPLICATE`
- `DYNAMIC`

E

- `EACH` (R)
- `ELSE` (R)
- `ELSEIF` (R)
- `EMPTY` (R); added in 8.0.4 (reserved)
- `ENABLE`
- `ENCLOSED` (R)
- `ENCRYPTION`
- `END`
- `ENDS`
- `ENFORCED`; added in 8.0.16 (nonreserved)
- `ENGINE`
- `ENGINES`
- `ENGINE_ATTRIBUTE`; added in 8.0.21 (nonreserved)

- `ENUM`
- `ERROR`
- `ERRORS`
- `ESCAPE`
- `ESCAPED (R)`
- `EVENT`
- `EVENTS`
- `EVERY`
- `EXCEPT (R)`
- `EXCHANGE`
- `EXCLUDE`; added in 8.0.2 (nonreserved)
- `EXECUTE`
- `EXISTS (R)`
- `EXIT (R)`
- `EXPANSION`
- `EXPIRE`
- `EXPLAIN (R)`
- `EXPORT`
- `EXTENDED`
- `EXTENT_SIZE`

F

- `FAILED_LOGIN_ATTEMPTS`; added in 8.0.19 (nonreserved)
- `FALSE (R)`
- `FAST`
- `FAULTS`
- `FETCH (R)`
- `FIELDS`
- `FILE`
- `FILE_BLOCK_SIZE`
- `FILTER`
- `FIRST`
- `FIRST_VALUE (R)`; added in 8.0.2 (reserved)
- `FIXED`

- `FLOAT` (R)
- `FLOAT4` (R)
- `FLOAT8` (R)
- `FLUSH`
- `FOLLOWING`; added in 8.0.2 (nonreserved)
- `FOLLOWS`
- `FOR` (R)
- `FORCE` (R)
- `FOREIGN` (R)
- `FORMAT`
- `FOUND`
- `FROM` (R)
- `FULL`
- `FULLTEXT` (R)
- `FUNCTION` (R); became reserved in 8.0.1

G

- `GENERAL`
- `GENERATED` (R)
- `GEOMCOLLECTION`; added in 8.0.11 (nonreserved)
- `GEOMETRY`
- `GEOMETRYCOLLECTION`
- `GET` (R)
- `GET_FORMAT`
- `GET_MASTER_PUBLIC_KEY`; added in 8.0.4 (reserved); became nonreserved in 8.0.11
- `GLOBAL`
- `GRANT` (R)
- `GRANTS`
- `GROUP` (R)
- `GROUPING` (R); added in 8.0.1 (reserved)
- `GROUPS` (R); added in 8.0.2 (reserved)
- `GROUP_REPLICATION`

H

- `HANDLER`

- `HASH`
- `HAVING` (R)
- `HELP`
- `HIGH_PRIORITY` (R)
- `HISTOGRAM`; added in 8.0.2 (nonreserved)
- `HISTORY`; added in 8.0.3 (nonreserved)
- `HOST`
- `HOSTS`

9.4 User-Defined Variables

You can store a value in a user-defined variable in one statement and refer to it later in another statement. This enables you to pass values from one statement to another.

User variables are written as `@var_name`, where the variable name `var_name` consists of alphanumeric characters, `.`, `_`, and `$`. A user variable name can contain other characters if you quote it as a string or identifier (for example, `@'my-var'`, `@"my-var"`, or `@`my-var``).

User-defined variables are session specific. A user variable defined by one client cannot be seen or used by other clients. (Exception: A user with access to the Performance Schema `user_variables_by_thread` table can see all user variables for all sessions.) All variables for a given client session are automatically freed when that client exits.

User variable names are not case-sensitive. Names have a maximum length of 64 characters.

One way to set a user-defined variable is by issuing a [SET](#) statement:

```
SET @var_name = expr [, @var_name = expr] ...
```

For [SET](#), either `=` or `:=` can be used as the assignment operator.

User variables can be assigned a value from a limited set of data types: integer, decimal, floating-point, binary or nonbinary string, or `NULL` value. Assignment of decimal and real values does not preserve the precision or scale of the value. A value of a type other than one of the permissible types is converted to a permissible type. For example, a value having a temporal or spatial data type is converted to a binary string. A value having the `JSON` data type is converted to a string with a character set of `utf8mb4` and a collation of `utf8mb4_bin`.

If a user variable is assigned a nonbinary (character) string value, it has the same character set and collation as the string. The coercibility of user variables is implicit. (This is the same coercibility as for table column values.)

Hexadecimal or bit values assigned to user variables are treated as binary strings. To assign a hexadecimal or bit value as a number to a user variable, use it in numeric context. For example, add 0 or use `CAST(... AS UNSIGNED)`:

```
mysql> SET @v1 = X'41';
mysql> SET @v2 = X'41'+0;
mysql> SET @v3 = CAST(X'41' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A | 65 | 65 |
+-----+-----+-----+
mysql> SET @v1 = b'1000001';
```

```
mysql> SET @v2 = b'1000001'+0;
mysql> SET @v3 = CAST(b'1000001' AS UNSIGNED);
mysql> SELECT @v1, @v2, @v3;
+-----+-----+-----+
| @v1 | @v2 | @v3 |
+-----+-----+-----+
| A   | 65  | 65  |
+-----+-----+-----+
```

If the value of a user variable is selected in a result set, it is returned to the client as a string.

If you refer to a variable that has not been initialized, it has a value of `NULL` and a type of string.

Beginning with MySQL 8.0.22, a user variable employed in a prepared statement has its type determined when the statement is first prepared, and retains this type each time the statement is executed thereafter. Similarly, the type of a user variable employed in a statement within a stored procedure is determined the first time the stored procedure is invoked, and retains this type with each subsequent invocation.

User variables may be used in most contexts where expressions are permitted. This does not currently include contexts that explicitly require a literal value, such as in the `LIMIT` clause of a `SELECT` statement, or the `IGNORE N LINES` clause of a `LOAD DATA` statement.

Previous releases of MySQL made it possible to assign a value to a user variable in statements other than `SET`. This functionality is supported in MySQL 8.0 for backward compatibility but is subject to removal in a future release of MySQL.

When making an assignment in this way, you must use `:=` as the assignment operator; `=` is treated as the comparison operator in statements other than `SET`.

The order of evaluation for expressions involving user variables is undefined. For example, there is no guarantee that `SELECT @a, @a:=@a+1` evaluates `@a` first and then performs the assignment.

In addition, the default result type of a variable is based on its type at the beginning of the statement. This may have unintended effects if a variable holds a value of one type at the beginning of a statement in which it is also assigned a new value of a different type.

To avoid problems with this behavior, either do not assign a value to and read the value of the same variable within a single statement, or else set the variable to `0`, `0.0`, or `' '` to define its type before you use it.

`HAVING`, `GROUP BY`, and `ORDER BY`, when referring to a variable that is assigned a value in the select expression list do not work as expected because the expression is evaluated on the client and thus can use stale column values from a previous row.

User variables are intended to provide data values. They cannot be used directly in an SQL statement as an identifier or as part of an identifier, such as in contexts where a table or database name is expected, or as a reserved word such as `SELECT`. This is true even if the variable is quoted, as shown in the following example:

```
mysql> SELECT c1 FROM t;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> SET @col = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
```

```

| @col |
+-----+
| c1   |
+-----+
1 row in set (0.00 sec)

mysql> SELECT `@col` FROM t;
ERROR 1054 (42S22): Unknown column '@col' in 'field list'

mysql> SET @col = "`c1`";
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @col FROM t;
+-----+
| @col |
+-----+
| `c1` |
+-----+
1 row in set (0.00 sec)

```

An exception to this principle that user variables cannot be used to provide identifiers, is when you are constructing a string for use as a prepared statement to execute later. In this case, user variables can be used to provide any part of the statement. The following example illustrates how this can be done:

```

mysql> SET @c = "c1";
Query OK, 0 rows affected (0.00 sec)

mysql> SET @s = CONCAT("SELECT ", @c, " FROM t");
Query OK, 0 rows affected (0.00 sec)

mysql> PREPARE stmt FROM @s;
Query OK, 0 rows affected (0.04 sec)
Statement prepared

mysql> EXECUTE stmt;
+-----+
| c1 |
+-----+
| 0 |
+-----+
| 1 |
+-----+
2 rows in set (0.00 sec)

mysql> DEALLOCATE PREPARE stmt;
Query OK, 0 rows affected (0.00 sec)

```

See [Section 13.5, “Prepared Statements”](#), for more information.

A similar technique can be used in application programs to construct SQL statements using program variables, as shown here using PHP 5:

```

<?php
    $mysqli = new mysqli("localhost", "user", "pass", "test");

    if( mysqli_connect_errno() )
        die("Connection failed: %s\n", mysqli_connect_error());

    $col = "c1";

    $query = "SELECT $col FROM t";

    $result = $mysqli->query($query);

    while($row = $result->fetch_assoc())
    {
        echo "<p>" . $row["$col"] . "</p>\n";
    }

    $result->close();

```

```
$mysql->close();
?>
```

Assembling an SQL statement in this fashion is sometimes known as “Dynamic SQL”.

9.5 Expressions

This section lists the grammar rules that expressions must follow in MySQL and provides additional information about the types of terms that may appear in expressions.

- [Expression Syntax](#)
- [Expression Term Notes](#)
- [Temporal Intervals](#)

Expression Syntax

The following grammar rules define expression syntax in MySQL. The grammar shown here is based on that given in the `sql/sql_yacc.yy` file of MySQL source distributions. For additional information about some of the expression terms, see [Expression Term Notes](#).

```
expr:
    expr OR expr
  | expr || expr
  | expr XOR expr
  | expr AND expr
  | expr && expr
  | NOT expr
  | ! expr
  | boolean_primary IS [NOT] {TRUE | FALSE | UNKNOWN}
  | boolean_primary

boolean_primary:
    boolean_primary IS [NOT] NULL
  | boolean_primary <=> predicate
  | boolean_primary comparison_operator predicate
  | boolean_primary comparison_operator {ALL | ANY} (subquery)
  | predicate

comparison_operator: = | >= | > | <= | < | <> | !=

predicate:
    bit_expr [NOT] IN (subquery)
  | bit_expr [NOT] IN (expr [, expr] ...)
  | bit_expr [NOT] BETWEEN bit_expr AND predicate
  | bit_expr SOUNDS LIKE bit_expr
  | bit_expr [NOT] LIKE simple_expr [ESCAPE simple_expr]
  | bit_expr [NOT] REGEXP bit_expr
  | bit_expr

bit_expr:
    bit_expr | bit_expr
  | bit_expr & bit_expr
  | bit_expr << bit_expr
  | bit_expr >> bit_expr
  | bit_expr + bit_expr
  | bit_expr - bit_expr
  | bit_expr * bit_expr
  | bit_expr / bit_expr
  | bit_expr DIV bit_expr
  | bit_expr MOD bit_expr
  | bit_expr % bit_expr
  | bit_expr ^ bit_expr
  | bit_expr + interval_expr
  | bit_expr - interval_expr
  | simple_expr
```

```

simple_expr:
  literal
  | identifier
  | function_call
  | simple_expr COLLATE collation_name
  | param_marker
  | variable
  | simple_expr || simple_expr
  | + simple_expr
  | - simple_expr
  | ~ simple_expr
  | ! simple_expr
  | BINARY simple_expr
  | (expr [, expr] ...)
  | ROW (expr, expr [, expr] ...)
  | (subquery)
  | EXISTS (subquery)
  | {identifier expr}
  | match_expr
  | case_expr
  | interval_expr

```

For operator precedence, see [Section 12.4.1, “Operator Precedence”](#). The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical `OR` operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See [Section 5.1.11, “Server SQL Modes”](#).

Expression Term Notes

For literal value syntax, see [Section 9.1, “Literal Values”](#).

For identifier syntax, see [Section 9.2, “Schema Object Names”](#).

Variables can be user variables, system variables, or stored program local variables or parameters:

- User variables: [Section 9.4, “User-Defined Variables”](#)
- System variables: [Section 5.1.9, “Using System Variables”](#)
- Stored program local variables: [Section 13.6.4.1, “Local Variable DECLARE Statement”](#)
- Stored program parameters: [Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#)

`param_marker` is `?` as used in prepared statements for placeholders. See [Section 13.5.1, “PREPARE Statement”](#).

`(subquery)` indicates a subquery that returns a single value; that is, a scalar subquery. See [Section 13.2.11.1, “The Subquery as Scalar Operand”](#).

`{identifier expr}` is ODBC escape syntax and is accepted for ODBC compatibility. The value is `expr`. The `{` and `}` curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

`match_expr` indicates a `MATCH` expression. See [Section 12.10, “Full-Text Search Functions”](#).

`case_expr` indicates a `CASE` expression. See [Section 12.5, “Flow Control Functions”](#).

`interval_expr` represents a temporal interval. See [Temporal Intervals](#).

Temporal Intervals

interval_expr in expressions represents a temporal interval. Intervals have this syntax:

```
INTERVAL expr unit
```

expr represents a quantity. *unit* represents the unit for interpreting the quantity; it is a specifier such as `HOURL`, `DAY`, or `WEEK`. The `INTERVAL` keyword and the *unit* specifier are not case sensitive.

The following table shows the expected form of the *expr* argument for each *unit* value.

Table 9.2 Temporal Interval Expression and Unit Arguments

<i>unit</i> Value	Expected <i>expr</i> Format
<code>MICROSECOND</code>	<code>MICROSECONDS</code>
<code>SECOND</code>	<code>SECONDS</code>
<code>MINUTE</code>	<code>MINUTES</code>
<code>HOURL</code>	<code>HOURS</code>
<code>DAY</code>	<code>DAYS</code>
<code>WEEK</code>	<code>WEEKS</code>
<code>MONTH</code>	<code>MONTHS</code>
<code>QUARTER</code>	<code>QUARTERS</code>
<code>YEAR</code>	<code>YEARS</code>
<code>SECOND_MICROSECOND</code>	<code>'SECONDS.MICROSECONDS'</code>
<code>MINUTE_MICROSECOND</code>	<code>'MINUTES:SECONDS.MICROSECONDS'</code>
<code>MINUTE_SECOND</code>	<code>'MINUTES:SECONDS'</code>
<code>HOURL_MICROSECOND</code>	<code>'HOURS:MINUTES:SECONDS.MICROSECONDS'</code>
<code>HOURL_SECOND</code>	<code>'HOURS:MINUTES:SECONDS'</code>
<code>HOURL_MINUTE</code>	<code>'HOURS:MINUTES'</code>
<code>DAY_MICROSECOND</code>	<code>'DAYS HOURS:MINUTES:SECONDS.MICROSECONDS'</code>
<code>DAY_SECOND</code>	<code>'DAYS HOURS:MINUTES:SECONDS'</code>
<code>DAY_MINUTE</code>	<code>'DAYS HOURS:MINUTES'</code>
<code>DAY_HOURL</code>	<code>'DAYS HOURS'</code>
<code>YEAR_MONTH</code>	<code>'YEARS-MONTHS'</code>

MySQL permits any punctuation delimiter in the *expr* format. Those shown in the table are the suggested delimiters.

Temporal intervals are used for certain functions, such as `DATE_ADD()` and `DATE_SUB()`:

```
mysql> SELECT DATE_ADD('2018-05-01',INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01',INTERVAL 1 YEAR);
-> '2017-05-01'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2021-01-01 00:00:00'
mysql> SELECT DATE_ADD('2018-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00',
```

```

-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'

```

Temporal arithmetic also can be performed in expressions using `INTERVAL` together with the `+` or `-` operator:

```

date + INTERVAL expr unit
date - INTERVAL expr unit

```

`INTERVAL expr unit` is permitted on either side of the `+` operator if the expression on the other side is a date or datetime value. For the `-` operator, `INTERVAL expr unit` is permitted only on the right side, because it makes no sense to subtract a date or datetime value from an interval.

```

mysql> SELECT '2018-12-31 23:59:59' + INTERVAL 1 SECOND;
-> '2019-01-01 00:00:00'
mysql> SELECT INTERVAL 1 DAY + '2018-12-31';
-> '2019-01-01'
mysql> SELECT '2025-01-01' - INTERVAL 1 SECOND;
-> '2024-12-31 23:59:59'

```

The `EXTRACT()` function uses the same kinds of *unit* specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic:

```

mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907

```

Temporal intervals can be used in `CREATE EVENT` statements:

```

CREATE EVENT myevent
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
DO
UPDATE myschema.mytable SET mycol = mycol + 1;

```

If you specify an interval value that is too short (does not include all the interval parts that would be expected from the *unit* keyword), MySQL assumes that you have left out the leftmost parts of the interval value. For example, if you specify a *unit* of `DAY_SECOND`, the value of *expr* is expected to have days, hours, minutes, and seconds parts. If you specify a value like `'1:10'`, MySQL assumes that the days and hours parts are missing and the value represents minutes and seconds. In other words, `'1:10' DAY_SECOND` is interpreted in such a way that it is equivalent to `'1:10' MINUTE_SECOND`. This is analogous to the way that MySQL interprets `TIME` values as representing elapsed time rather than as a time of day.

expr is treated as a string, so be careful if you specify a nonstring value with `INTERVAL`. For example, with an interval specifier of `HOURL_MINUTE`, `'6/4'` is treated as 6 hours, four minutes, whereas `6/4` evaluates to `1.5000` and is treated as 1 hour, 5000 minutes:

```

mysql> SELECT '6/4', 6/4;
-> 1.5000
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL '6/4' HOURL_MINUTE);
-> '2019-01-01 06:04:00'
mysql> SELECT DATE_ADD('2019-01-01', INTERVAL 6/4 HOURL_MINUTE);
-> '2019-01-04 12:20:00'

```

To ensure interpretation of the interval value as you expect, a `CAST()` operation may be used. To treat `6/4` as 1 hour, 5 minutes, cast it to a `DECIMAL` value with a single fractional digit:

```

mysql> SELECT CAST(6/4 AS DECIMAL(3,1));

```

```
mysql> SELECT DATE_ADD('1970-01-01 12:00:00',
    -> INTERVAL CAST(6/4 AS DECIMAL(3,1)) HOUR_MINUTE);
    -> '1970-01-01 13:05:00'
```

If you add to or subtract from a date value something that contains a time part, the result is automatically converted to a datetime value:

```
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 DAY);
    -> '2023-01-02'
mysql> SELECT DATE_ADD('2023-01-01', INTERVAL 1 HOUR);
    -> '2023-01-01 01:00:00'
```

If you add `MONTH`, `YEAR_MONTH`, or `YEAR` and the resulting date has a day that is larger than the maximum day for the new month, the day is adjusted to the maximum days in the new month:

```
mysql> SELECT DATE_ADD('2019-01-30', INTERVAL 1 MONTH);
    -> '2019-02-28'
```

Date arithmetic operations require complete dates and do not work with incomplete dates such as `'2016-07-00'` or badly malformed dates:

```
mysql> SELECT DATE_ADD('2016-07-00', INTERVAL 1 DAY);
    -> NULL
mysql> SELECT '2005-03-32' + INTERVAL 1 MONTH;
    -> NULL
```

9.6 Comment Syntax

MySQL Server supports three comment styles:

- From a `#` character to the end of the line.
- From a `--` sequence to the end of the line. In MySQL, the `--` (double-dash) comment style requires the second dash to be followed by at least one whitespace or control character (such as a space, tab, newline, and so on). This syntax differs slightly from standard SQL comment syntax, as discussed in [Section 1.7.2.4, “--' as the Start of a Comment”](#).
- From a `/*` sequence to the following `*/` sequence, as in the C programming language. This syntax enables a comment to extend over multiple lines because the beginning and closing sequences need not be on the same line.

The following example demonstrates all three comment styles:

```
mysql> SELECT 1+1;      # This comment continues to the end of line
mysql> SELECT 1+1;      -- This comment continues to the end of line
mysql> SELECT 1 /* this is an in-line comment */ + 1;
mysql> SELECT 1+
/*
this is a
multiple-line comment
*/
1;
```

Nested comments are not supported, are deprecated, and will be removed in a future MySQL release. (Under some conditions, nested comments might be permitted, but usually are not, and users should avoid them.)

MySQL Server supports certain variants of C-style comments. These enable you to write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ coll FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `KEY_BLOCK_SIZE` keyword in the following comment is executed only by servers from MySQL 5.1.10 or higher:

```
CREATE TABLE t1(a INT, KEY (a)) /*!50110 KEY_BLOCK_SIZE=1024 */;
```

The comment syntax just described applies to how the `mysqld` server parses SQL statements. The `mysql` client program also performs some parsing of statements before sending them to the server. (It does this to determine statement boundaries within a multiple-statement input line.) For information about differences between the server and `mysql` client parsers, see [Section 4.5.1.6, “mysql Client Tips”](#).

Comments in `/*!12345 ... */` format are not stored on the server. If this format is used to comment stored programs, the comments are not retained in the program body.

Another variant of C-style comment syntax is used to specify optimizer hints. Hint comments include a `+` character following the `/*` comment opening sequence. Example:

```
SELECT /*+ BKA(t1) */ FROM ... ;
```

For more information, see [Section 8.9.3, “Optimizer Hints”](#).

The use of short-form `mysql` commands such as `\C` within multiple-line `/* ... */` comments is not supported. Short-form commands do work within single-line `/*! ... */` version comments, as do `/*+ ... */` optimizer-hint comments, which are stored in object definitions. If there is a concern that optimizer-hint comments may be stored in object definitions so that dump files when reloaded with `mysql` would result in execution of such commands, either invoke `mysql` with the `--binary-mode` option or use a reload client other than `mysql`.

Chapter 10 Character Sets, Collations, Unicode

Table of Contents

10.1 Character Sets and Collations in General	1704
10.2 Character Sets and Collations in MySQL	1705

10.14.2 Choosing a Collation ID	1769
10.14.3 Adding a Simple Collation to an 8-Bit Character Set	1769
10.14.4 Adding a UCA Collation to a Unicode Character Set	1770
10.15 Character Set Configuration	1777
10.16 MySQL Server Locale Support	1778

MySQL includes character set support that enables you to store data using a variety of character sets and perform comparisons according to a variety of collations. The default MySQL server character set and collation are `utf8mb4` and `utf8mb4_0900_ai_ci`, but you can specify character sets at the server, database, table, column, and string literal levels.

This chapter discusses the following topics:

- What are character sets and collations?
- The multiple-level default system for character set assignment.
- Syntax for specifying character sets and collations.
- Affected functions and operations.
- Unicode support.
- The character sets and collations that are available, with notes.
- Selecting the language for error messages.
- Selecting the locale for day and month names.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8';
```

For more information about configuring character sets for application use and character set-related issues in client/server communication, see [Section 10.5, “Configuring Application Character Set and Collation”](#), and [Section 10.4, “Connection Character Sets and Collations”](#).

10.1 Character Sets and Collations in General

A *character set* is a set of symbols and encodings. A *collation* is a set of rules for comparing characters in a character set. Let's make the distinction clear with an example of an imaginary character set.

Suppose that we have an alphabet with four letters: `A`, `B`, `a`, `b`. We give each letter a number: `A` = 0, `B` = 1, `a` = 2, `b` = 3. The letter `A` is a symbol, the number 0 is the *encoding* for `A`, and the combination of all four letters and their encodings is a *character set*.

Suppose that we want to compare two string values, `A` and `B`. The simplest way to do this is to look at the encodings: 0 for `A` and 1 for `B`. Because 0 is less than 1, we say `A` is less than `B`. What we've just done is apply a collation to our character set. The collation is a set of rules (only one rule in this case): “compare the encodings.” We call this simplest of all possible collations a *binary* collation.

But what if we want to say that the lowercase and uppercase letters are equivalent? Then we would have at least two rules: (1) treat the lowercase letters `a` and `b` as equivalent to `A` and `B`; (2) then compare the encodings. We call this a *case-insensitive* collation. It is a little more complex than a binary collation.

In real life, most character sets have many characters: not just `A` and `B` but whole alphabets, sometimes multiple alphabets or eastern writing systems with thousands of characters, along with many special symbols and punctuation marks. Also in real life, most collations have many rules, not

just for whether to distinguish lettercase, but also for whether to distinguish accents (an “accent” is a mark attached to a character as in German `ö`), and for multiple-character mappings (such as the rule that `ö` = `oe` in one of the two German collations).

MySQL can do these things for you:

- Store strings using a variety of character sets.
- Compare strings using a variety of collations.
- Mix strings with different character sets or collations in the same server, the same database, or even the same table.
- Enable specification of character set and collation at any level.

To use these features effectively, you must know what character sets and collations are available, how to change the defaults, and how they affect the behavior of string operators and functions.

10.2 Character Sets and Collations in MySQL

MySQL Server supports multiple character sets, including several Unicode character sets. To display the available character sets, use the `INFORMATION_SCHEMA.CHARACTER_SETS` table or the `SHOW CHARACTER SET` statement. A partial listing follows. For more complete information, see [Section 10.10, “Supported Character Sets and Collations”](#).

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
binary	Binary pseudo charset	binary	1
...			
latin1	cp1252 West European	latin1_swedish_ci	1
...			
ucs2	UCS-2 Unicode	ucs2_general_ci	2
...			
utf8	UTF-8 Unicode	utf8_general_ci	3
utf8mb4	UTF-8 Unicode	utf8mb4_0900_ai_ci	4
...			

By default, the `SHOW CHARACTER SET` statement displays all available character sets. It takes an optional `LIKE` or `WHERE` clause that indicates which character set names to match. The following example shows some of the Unicode character sets (those based on Unicode Transformation Format):

```
mysql> SHOW CHARACTER SET LIKE 'utf%';
```

Charset	Description	Default collation	Maxlen
utf16	UTF-16 Unicode	utf16_general_ci	4
utf16le	UTF-16LE Unicode	utf16le_general_ci	4
utf32	UTF-32 Unicode	utf32_general_ci	4
utf8	UTF-8 Unicode	utf8_general_ci	3
utf8mb4	UTF-8 Unicode	utf8mb4_0900_ai_ci	4

A given character set always has at least one collation, and most character sets have several. To list the display collations for a character set, use the `INFORMATION_SCHEMA.COLLATIONS` table or the `SHOW COLLATION` statement.

By default, the `SHOW COLLATION` statement displays all available collations. It takes an optional `LIKE` or `WHERE` clause that indicates which collation names to display. For example, to see the collations for the default character set, `utf8mb4`, use this statement:

```
mysql> SHOW COLLATION WHERE Charset = 'utf8mb4';
```

Collation	Charset	Id	Default	Compiled	Sortlen	Pad_attribute
utf8mb4_0900_ai_ci	utf8mb4	255	Yes	Yes	0	NO PAD

Character Sets and Collations in MySQL

utf8mb4_0900_as_ci	utf8mb4	305	Yes	0	NO PAD

utf8mb4_vi_0900_as_cs	utf8mb4	300	Yes	0	NO PAD
utf8mb4_zh_0900_as_cs	utf8mb4	308	Yes	0	NO PAD

For more information about those collations, see [Section 10.10.1, “Unicode Character Sets”](#).

Collations have these general characteristics:

- Two different character sets cannot have the same collation.
- Each character set has a *default collation*. For example, the default collations for `utf8mb4` and `latin1` are `utf8mb4_0900_ai_ci` and `latin1_swedish_ci`, respectively. The `INFORMATION_SCHEMA.CHARACTER_SETS` table and the `SHOW CHARACTER SET` statement indicate the default collation for each character set. The `INFORMATION_SCHEMA.COLLATIONS` table and the `SHOW COLLATION` statement have a column that indicates for each collation whether it is the default for its character set (`Yes` if so, empty if not).
- Collation names start with the name of the character set with which they are associated, generally followed by one or more suffixes indicating other collation characteristics. For additional information about naming conventions, see [Section 10.3.1, “Collation Naming Conventions”](#).

When a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing an inappropriate collation, perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

10.2.1 Character Set Repertoire

The *repertoire* of a character set is the collection of characters in the set.

String expressions have a repertoire attribute, which can have two values:

- **ASCII**: The expression can contain only ASCII characters; that is, characters in the Unicode range `U+0000` to `U+007F`.
- **UNICODE**: The expression can contain characters in the Unicode range `U+0000` to `U+10FFFF`. This includes characters in the Basic Multilingual Plane (BMP) range (`U+0000` to `U+FFFF`) and supplementary characters outside the BMP range (`U+10000` to `U+10FFFF`).

The **ASCII** range is a subset of **UNICODE** range, so a string with **ASCII** repertoire can be converted safely without loss of information to the character set of any string with **UNICODE** repertoire. It can also be converted safely to any character set that is a superset of the `ascii` character set. (All MySQL character sets are supersets of `ascii` with the exception of `swe7`, which reuses some punctuation characters for Swedish accented characters.)

The use of repertoire enables character set conversion in expressions for many cases where MySQL would otherwise return an “illegal mix of collations” error when the rules for collation coercibility are insufficient to resolve ambiguities. (For information about coercibility, see [Section 10.8.4, “Collation Coercibility in Expressions”](#).)

The following discussion provides examples of expressions and their repertoires, and describes how the use of repertoire changes string expression evaluation:

- The repertoire for a string constant depends on string content and may differ from the repertoire of the string character set. Consider these statements:

```
SET NAMES utf8mb4; SELECT 'abc';
SELECT _utf8mb4'def';
```

Although the character set is `utf8mb4` in each of the preceding cases, the strings do not actually contain any characters outside the ASCII range, so their repertoire is **ASCII** rather than **UNICODE**.

- A column having the `ascii` character set has **ASCII** repertoire because of its character set. In the following table, `c1` has **ASCII** repertoire:

```
CREATE TABLE t1 (c1 CHAR(1) CHARACTER SET ascii);
```

The following example illustrates how repertoire enables a result to be determined in a case where an error occurs without repertoire:

```
CREATE TABLE t1 (
  c1 CHAR(1) CHARACTER SET latin1,
  c2 CHAR(1) CHARACTER SET ascii
);
INSERT INTO t1 VALUES ('a','b');
SELECT CONCAT(c1,c2) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (ascii_general_ci,IMPLICIT) for operation 'concat'
```

Using repertoire, subset to superset ([ascii](#) to [latin1](#)) conversion can occur and a result is returned:

```
+-----+
| CONCAT(c1,c2) |
+-----+
| ab            |
+-----+
```

- Functions with one string argument inherit the repertoire of their argument. The result of `UPPER(_utf8mb4'abc')` has [ASCII](#) repertoire because its argument has [ASCII](#) repertoire. (Despite the `_utf8mb4` introducer, the string `'abc'` contains no characters outside the ASCII range.)
- For functions that return a string but do not have string arguments and use `character_set_connection` as the result character set, the result repertoire is [ASCII](#) if `character_set_connection` is [ascii](#), and [UNICODE](#) otherwise:

```
FORMAT(numeric_column, 4);
```

Use of repertoire changes how MySQL evaluates the following example:

```
SET NAMES ascii;
CREATE TABLE t1 (a INT, b VARCHAR(10) CHARACTER SET latin1);
INSERT INTO t1 VALUES (1,'b');
SELECT CONCAT(FORMAT(a, 4), b) FROM t1;
```

Without repertoire, this error occurs:

```
ERROR 1267 (HY000): Illegal mix of collations (ascii_general_ci,COERCIBLE)
and (latin1_swedish_ci,IMPLICIT) for operation 'concat'
```

With repertoire, a result is returned:

```
+-----+
| CONCAT(FORMAT(a, 4), b) |
+-----+
| 1.0000b                |
+-----+
```

- Functions with two or more string arguments use the “widest” argument repertoire for the result repertoire, where [UNICODE](#) is wider than [ASCII](#). Consider the following `CONCAT()` calls:

```
CONCAT(_ucs2 X'0041', _ucs2 X'0042')
CONCAT(_ucs2 X'0041', _ucs2 X'00C2')
```

For the first call, the repertoire is [ASCII](#) because both arguments are within the ASCII range. For the second call, the repertoire is [UNICODE](#) because the second argument is outside the ASCII range.

- The repertoire for function return values is determined based on the repertoire of only those arguments that affect the result's character set and collation.

```
IF(column1 < column2, 'smaller', 'greater')
```

The result repertoire is [ASCII](#) because the two string arguments (the second argument and the third argument) both have [ASCII](#) repertoire. The first argument does not matter for the result repertoire, even if the expression uses string values.

10.2.2 UTF-8 for Metadata

Metadata is “the data about the data.” Anything that *describes* the database—as opposed to being the *contents* of the database—is metadata. Thus column names, database names, user names, version names, and most of the string results from [SHOW](#) are metadata. This is also true of the contents of tables in [INFORMATION_SCHEMA](#) because those tables by definition contain information about database objects.

Representation of metadata must satisfy these requirements:

- All metadata must be in the same character set. Otherwise, neither the [SHOW](#) statements nor [SELECT](#) statements for tables in [INFORMATION_SCHEMA](#) would work properly because different rows in the same column of the results of these operations would be in different character sets.
- Metadata must include all characters in all languages. Otherwise, users would not be able to name columns and tables using their own languages.

To satisfy both requirements, MySQL stores metadata in a Unicode character set, namely UTF-8. This does not cause any disruption if you never use accented or non-Latin characters. But if you do, you should be aware that metadata is in UTF-8.

The metadata requirements mean that the return values of the [USER\(\)](#), [CURRENT_USER\(\)](#), [SESSION_USER\(\)](#), [SYSTEM_USER\(\)](#), [DATABASE\(\)](#), and [VERSION\(\)](#) functions have the UTF-8 character set by default.

The server sets the [character_set_system](#) system variable to the name of the metadata character set:

```
mysql> SHOW VARIABLES LIKE 'character_set_system';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_system | utf8 |
+-----+-----+
```

Storage of metadata using Unicode does *not* mean that the server returns headers of columns and the results of [DESCRIBE](#) functions in the [character_set_system](#) character set by default. When you use [SELECT column1 FROM t](#), the name [column1](#) itself is returned from the server to the client in the character set determined by the value of the [character_set_results](#) system variable, which has a default value of [utf8mb4](#). If you want the server to pass metadata results back in a different character set, use the [SET NAMES](#) statement to force the server to perform character set conversion. [SET NAMES](#) sets the [character_set_results](#) and other related system variables. (See [Section 10.4, “Connection Character Sets and Collations”](#).) Alternatively, a client program can perform the conversion after receiving the result from the server. It is more efficient for the client to perform the conversion, but this option is not always available for all clients.

If [character_set_results](#) is set to [NULL](#), no conversion is performed and the server returns metadata using its original character set (the set indicated by [character_set_system](#)).

Error messages returned from the server to the client are converted to the client character set automatically, as with metadata.

If you are using (for example) the [USER\(\)](#) function for comparison or assignment within a single statement, don't worry. MySQL performs some automatic conversion for you.

```
SELECT * FROM t1 WHERE USER() = latin1_column;
```

This works because the contents of `latin1_column` are automatically converted to UTF-8 before the comparison.

```
INSERT INTO t1 (latin1_column) SELECT USER();
```

This works because the contents of `USER()` are automatically converted to `latin1` before the assignment.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. For more information about coercion of strings, see [Section 10.8.4, “Collation Coercibility in Expressions”](#).

10.3 Specifying Character Sets and Collations

There are default settings for character sets and collations at four levels: server, database, table, and column. The description in the following sections may appear complex, but it has been found in practice that multiple-level defaulting leads to natural and obvious results.

`CHARACTER SET` is used in clauses that specify a character set. `CHARSET` can be used as a synonym for `CHARACTER SET`.

Character set issues affect not only data storage, but also communication between client programs and the MySQL server. If you want the client program to communicate with the server using a character set different from the default, you'll need to indicate which one. For example, to use the `utf8mb4` Unicode character set, issue this statement after connecting to the server:

```
SET NAMES 'utf8mb4';
```

For more information about character set-related issues in client/server communication, see [Section 10.4, “Connection Character Sets and Collations”](#).

10.3.1 Collation Naming Conventions

MySQL collation names follow these conventions:

- A collation name starts with the name of the character set with which it is associated, generally followed by one or more suffixes indicating other collation characteristics. For example, `utf8mb4_general_ci` and `latin1_swedish_ci` are collations for the `utf8mb4` and `latin1` character sets, respectively. The `binary` character set has a single collation, also named `binary`, with no suffixes.
- A language-specific collation includes a locale code or language name. For example, `utf8mb4_tr_0900_ai_ci` and `utf8mb4_hu_0900_ai_ci` sort characters for the `utf8mb4` character set using the rules of Turkish and Hungarian, respectively. `utf8mb4_turkish_ci` and `utf8mb4_hungarian_ci` are similar but based on a less recent version of the Unicode Collation Algorithm.
- Collation suffixes indicate whether a collation is case-sensitive, accent-sensitive, or kana-sensitive (or some combination thereof), or binary. The following table shows the suffixes used to indicate these characteristics.

Table 10.1 Collation Suffix Meanings

Suffix	Meaning
<code>_ai</code>	Accent-insensitive
<code>_as</code>	Accent-sensitive
<code>_ci</code>	Case-insensitive

Suffix	Meaning
<code>_cs</code>	Case-sensitive
<code>_ks</code>	Kana-sensitive
<code>_bin</code>	Binary

For nonbinary collation names that do not specify accent sensitivity, it is determined by case sensitivity. If a collation name does not contain `_ai` or `_as`, `_ci` in the name implies `_ai` and `_cs` in the name implies `_as`. For example, `latin1_general_ci` is explicitly case-insensitive and implicitly accent-insensitive, `latin1_general_cs` is explicitly case-sensitive and implicitly accent-sensitive, and `utf8mb4_0900_ai_ci` is explicitly case-insensitive and accent-insensitive.

For Japanese collations, the `_ks` suffix indicates that a collation is kana-sensitive; that is, it distinguishes Katakana characters from Hiragana characters. Japanese collations without the `_ks` suffix are not kana-sensitive and treat Katakana and Hiragana characters equal for sorting.

For the `binary` collation of the `binary` character set, comparisons are based on numeric byte values. For the `_bin` collation of a nonbinary character set, comparisons are based on numeric character code values, which differ from byte values for multibyte characters. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 10.8.5, “The binary Collation Compared to `_bin` Collations”](#).

- Collation names for Unicode character sets may include a version number to indicate the version of the Unicode Collation Algorithm (UCA) on which the collation is based. UCA-based collations without a version number in the name use the version-4.0.0 UCA weight keys. For example:
 - `utf8mb4_0900_ai_ci` is based on UCA 9.0.0 weight keys (<http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt>).
 - `utf8mb4_unicode_520_ci` is based on UCA 5.2.0 weight keys (<http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>).
 - `utf8mb4_unicode_ci` (with no version named) is based on UCA 4.0.0 weight keys (<http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>).
- For Unicode character sets, the `xxx_general_mysql500_ci` collations preserve the pre-5.1.24 ordering of the original `xxx_general_ci` collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

10.3.2 Server Character Set and Collation

MySQL Server has a server character set and a server collation. By default, these are `utf8mb4` and `utf8mb4_0900_ai_ci`, but they can be set explicitly at server startup on the command line or in an option file and changed at runtime.

Initially, the server character set and collation depend on the options that you use when you start `mysqld`. You can use `--character-set-server` for the character set. Along with it, you can add `--collation-server` for the collation. If you don't specify a character set, that is the same as saying `--character-set-server=utf8mb4`. If you specify only a character set (for example, `utf8mb4`) but not a collation, that is the same as saying `--character-set-server=utf8mb4 --collation-server=utf8mb4_0900_ai_ci` because `utf8mb4_0900_ai_ci` is the default collation for `utf8mb4`. Therefore, the following three commands all have the same effect:

```
mysqld
mysqld --character-set-server=utf8mb4
mysqld --character-set-server=utf8mb4 \
  --collation-server=utf8mb4_0900_ai_ci
```

One way to change the settings is by recompiling. To change the default server character set and collation when building from sources, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` options for `CMake`. For example:

```
cmake . -DDEFAULT_CHARSET=latin1
```

Or:

```
cmake . -DDEFAULT_CHARSET=latin1 \
-DDEFAULT_COLLATION=latin1_german1_ci
```

Both `mysqld` and `CMake` verify that the character set/collation combination is valid. If not, each program displays an error message and terminates.

The server character set and collation are used as default values if the database character set and collation are not specified in `CREATE DATABASE` statements. They have no other purpose.

The current server character set and collation can be determined from the values of the `character_set_server` and `collation_server` system variables. These variables can be changed at runtime.

10.3.3 Database Character Set and Collation

Every database has a database character set and a database collation. The `CREATE DATABASE` and `ALTER DATABASE` statements have optional clauses for specifying the database character set and collation:

```
CREATE DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
  [[DEFAULT] CHARACTER SET charset_name]
  [[DEFAULT] COLLATE collation_name]
```

The keyword `SCHEMA` can be used instead of `DATABASE`.

The `CHARACTER SET` and `COLLATE` clauses make it possible to create databases with different character sets and collations on the same MySQL server.

Database options are stored in the data dictionary and can be examined by checking the `INFORMATION_SCHEMA.SCHEMATA` table.

Example:

```
CREATE DATABASE db_name CHARACTER SET latin1 COLLATE latin1_swedish_ci;
```

MySQL chooses the database character set and database collation in the following manner:

- If both `CHARACTER SET charset_name` and `COLLATE collation_name` are specified, character set *charset_name* and collation *collation_name* are used.
- If `CHARACTER SET charset_name` is specified without `COLLATE`, character set *charset_name* and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `COLLATE collation_name` is specified without `CHARACTER SET`, the character set associated with *collation_name* and collation *collation_name* are used.
- Otherwise (neither `CHARACTER SET` nor `COLLATE` is specified), the server character set and server collation are used.

The character set and collation for the default database can be determined from the values of the `character_set_database` and `collation_database` system variables. The server sets these variables whenever the default database changes. If there is no default database, the variables have the same value as the corresponding server-level system variables, `character_set_server` and `collation_server`.

To see the default character set and collation for a given database, use these statements:

```
USE db_name;
SELECT @@character_set_database, @@collation_database;
```

Alternatively, to display the values without changing the default database:

```
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

The database character set and collation affect these aspects of server operation:

- For **CREATE TABLE** statements, the database character set and collation are used as default values for table definitions if the table character set and collation are not specified. To override this, provide explicit **CHARACTER SET** and **COLLATE** table options.
- For **LOAD DATA** statements that include no **CHARACTER SET** clause, the server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. To override this, provide an explicit **CHARACTER SET** clause.
- For stored routines (procedures and functions), the database character set and collation in effect at routine creation time are used as the character set and collation of character data parameters for which the declaration includes no **CHARACTER SET** or a **COLLATE** attribute. To override this, provide **CHARACTER SET** and **COLLATE** explicitly.

10.3.4 Table Character Set and Collation

Every table has a table character set and a table collation. The **CREATE TABLE** and **ALTER TABLE** statements have optional clauses for specifying the table character set and collation:

```
CREATE TABLE tbl_name (column_list)
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]]

ALTER TABLE tbl_name
  [[DEFAULT] CHARACTER SET charset_name]
  [COLLATE collation_name]
```

Example:

```
CREATE TABLE t1 ( ... )
CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

MySQL chooses the table character set and collation in the following manner:

- If both **CHARACTER SET *charset_name*** and **COLLATE *collation_name*** are specified, character set *charset_name* and collation *collation_name* are used.
- If **CHARACTER SET *charset_name*** is specified without **COLLATE**, character set *charset_name* and its default collation are used. To see the default collation for each character set, use the **SHOW CHARACTER SET** statement or query the **INFORMATION_SCHEMA.CHARACTER_SETS** table.
- If **COLLATE *collation_name*** is specified without **CHARACTER SET**, the character set associated with *collation_name* and collation *collation_name* are used.
- Otherwise (neither **CHARACTER SET** nor **COLLATE** is specified), the database character set and collation are used.

The table character set and collation are used as default values for column definitions if the column character set and collation are not specified in individual column definitions. The table character set and collation are MySQL extensions; there are no such things in standard SQL.

10.3.5 Column Character Set and Collation

Every “character” column (that is, a column of type **CHAR**, **VARCHAR**, a **TEXT** type, or any synonym) has a column character set and a column collation. Column definition syntax for **CREATE TABLE** and **ALTER TABLE** has optional clauses for specifying the column character set and collation:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

These clauses can also be used for [ENUM](#) and [SET](#) columns:

```
col_name {ENUM | SET} (val_list)
[CHARACTER SET charset_name]
[COLLATE collation_name]
```

Examples:

```
CREATE TABLE t1
(
  col1 VARCHAR(5)
    CHARACTER SET latin1
    COLLATE latin1_german1_ci
);

ALTER TABLE t1 MODIFY
  col1 VARCHAR(5)
    CHARACTER SET latin1
    COLLATE latin1_swedish_ci;
```

MySQL chooses the column character set and collation in the following manner:

- If both [CHARACTER SET charset_name](#) and [COLLATE collation_name](#) are specified, character set [charset_name](#) and collation [collation_name](#) are used.

```
CREATE TABLE t1
(
  col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set and collation are specified for the column, so they are used. The column has character set [utf8](#) and collation [utf8_unicode_ci](#).

- If [CHARACTER SET charset_name](#) is specified without [COLLATE](#), character set [charset_name](#) and its default collation are used.

```
CREATE TABLE t1
(
  col1 CHAR(10) CHARACTER SET utf8
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The character set is specified for the column, but the collation is not. The column has character set [utf8](#) and the default collation for [utf8](#), which is [utf8_general_ci](#). To see the default collation for each character set, use the [SHOW CHARACTER SET](#) statement or query the [INFORMATION_SCHEMA.CHARACTER_SETS](#) table.

- If [COLLATE collation_name](#) is specified without [CHARACTER SET](#), the character set associated with [collation_name](#) and collation [collation_name](#) are used.

```
CREATE TABLE t1
(
  col1 CHAR(10) COLLATE utf8_polish_ci
) CHARACTER SET latin1 COLLATE latin1_bin;
```

The collation is specified for the column, but the character set is not. The column has collation [utf8_polish_ci](#) and the character set is the one associated with the collation, which is [utf8](#).

- Otherwise (neither [CHARACTER SET](#) nor [COLLATE](#) is specified), the table character set and collation are used.

```
CREATE TABLE t1
(
  col1 CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_bin;
```

Neither the character set nor collation is specified for the column, so the table defaults are used. The column has character set `latin1` and collation `latin1_bin`.

The `CHARACTER SET` and `COLLATE` clauses are standard SQL.

If you use `ALTER TABLE` to convert a column from one character set to another, MySQL attempts to map the data values, but if the character sets are incompatible, there may be data loss.

10.3.6 Character String Literal Character Set and Collation

Every character string literal has a character set and a collation.

For the simple statement `SELECT 'string'`, the string has the connection default character set and collation defined by the `character_set_connection` and `collation_connection` system variables.

A character string literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name]'string' [COLLATE collation_name]
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set `charset_name`.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal. See [Section 10.3.8, “Character Set Introducers”](#).

Examples:

```
SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8mb4'abc' COLLATE utf8mb4_danish_ci;
```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

MySQL determines the character set and collation of a character string literal in the following manner:

- If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.
- If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `_charset_name` is not specified but `COLLATE collation_name` is specified, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
- Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified), the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.

Examples:

- A nonbinary string with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
```

- A nonbinary string with `utf8mb4` character set and its default collation (that is, `utf8mb4_general_ci`):

```
SELECT _utf8mb4'Müller';
```

- A binary string with `binary` character set and its default collation (that is, `binary`):

```
SELECT _binary'Müller';
```

- A nonbinary string with the connection default character set and `utf8mb4_general_ci` collation (fails if the connection character set is not `utf8mb4`):

```
SELECT 'Müller' COLLATE utf8mb4_general_ci;
```

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

An introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`.

The following examples show that escape processing occurs using `character_set_connection` even in the presence of an introducer. The examples use `SET NAMES` (which changes `character_set_connection`, as discussed in [Section 10.4, “Connection Character Sets and Collations”](#)), and display the resulting strings using the `HEX()` function so that the exact string contents can be seen.

Example 1:

```
mysql> SET NAMES latin1;
mysql> SELECT HEX('à\n'), HEX(_sjis'à\n');
+-----+-----+
| HEX('à\n') | HEX(_sjis'à\n') |
+-----+-----+
| E00A      | E00A              |
+-----+-----+
```

Here, `à` (hexadecimal value `E0`) is followed by `\n`, the escape sequence for newline. The escape sequence is interpreted using the `character_set_connection` value of `latin1` to produce a literal newline (hexadecimal value `0A`). This happens even for the second string. That is, the `_sjis` introducer does not affect the parser's escape processing.

Example 2:

```
mysql> SET NAMES sjis;
mysql> SELECT HEX('à\n'), HEX(_latin1'à\n');
+-----+-----+
| HEX('à\n') | HEX(_latin1'à\n') |
+-----+-----+
| E05C6E     | E05C6E             |
+-----+-----+
```

Here, `character_set_connection` is `sjis`, a character set in which the sequence of `à` followed by `\` (hexadecimal values `05` and `5C`) is a valid multibyte character. Hence, the first two bytes of the string are interpreted as a single `sjis` character, and the `\` is not interpreted as an escape character. The following `n` (hexadecimal value `6E`) is not interpreted as part of an escape sequence. This is true even for the second string; the `_latin1` introducer does not affect escape processing.

10.3.7 The National Character Set

Standard SQL defines `NCHAR` or `NATIONAL CHAR` as a way to indicate that a `CHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. For example, these data type declarations are equivalent:

```
CHAR(10) CHARACTER SET utf8
NATIONAL CHARACTER(10)
NCHAR(10)
```

As are these:

```

VARCHAR(10) CHARACTER SET utf8
NATIONAL VARCHAR(10)
NVARCHAR(10)
NCHAR VARCHAR(10)
NATIONAL CHARACTER VARYING(10)
NATIONAL CHAR VARYING(10)

```

You can use `N'literal'` (or `n'literal'`) to create a string in the national character set. These statements are equivalent:

```

SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';

```

10.3.8 Character Set Introducers

A character string literal, hexadecimal literal, or bit-value literal may have an optional character set introducer and `COLLATE` clause, to designate it as a string that uses a particular character set and collation:

```
[_charset_name] literal [COLLATE collation_name]
```

The `_charset_name` expression is formally called an *introducer*. It tells the parser, “the string that follows uses character set *charset_name*.” An introducer does not change the string to the introducer character set like `CONVERT()` would do. It does not change the string value, although padding may occur. The introducer is just a signal.

For character string literals, space between the introducer and the string is permitted but optional.

For character set literals, an introducer indicates the character set for the following string, but does not change how the parser performs escape processing within the string. Escapes are always interpreted by the parser according to the character set given by `character_set_connection`. For additional discussion and examples, see [Section 10.3.6, “Character String Literal Character Set and Collation”](#).

Examples:

```

SELECT 'abc';
SELECT _latin1'abc';
SELECT _binary'abc';
SELECT _utf8mb4'abc' COLLATE utf8mb4_danish_ci;

SELECT _latin1 X'4D7953514C';
SELECT _utf8mb4 0x4D7953514C COLLATE utf8mb4_danish_ci;

SELECT _latin1 b'1000001';
SELECT _utf8mb4 0b1000001 COLLATE utf8mb4_danish_ci;

```

Character set introducers and the `COLLATE` clause are implemented according to standard SQL specifications.

Character string literals can be designated as binary strings by using the `_binary` introducer. Hexadecimal literals and bit-value literals are binary strings by default, so `_binary` is permitted, but normally unnecessary. `_binary` may be useful to preserve a hexadecimal or bit literal as a binary string in contexts for which the literal is otherwise treated as a number. For example, bit operations permit numeric or binary string arguments in MySQL 8.0 and higher, but treat hexadecimal and bit literals as numbers by default. To explicitly specify binary string context for such literals, use a `_binary` introducer for at least one of the arguments:

```

mysql> SET @v1 = X'000D' | X'0BC0';
mysql> SET @v2 = _binary X'000D' | X'0BC0';
mysql> SELECT HEX(@v1), HEX(@v2);
+-----+-----+
| HEX(@v1) | HEX(@v2) |
+-----+-----+

```

BCD	0BCD
+	+

The displayed result appears similar for both bit operations, but the result without `_binary` is a `BIGINT` value, whereas the result with `_binary` is a binary string. Due to the difference in result types, the displayed values differ: High-order 0 digits are not displayed for the numeric result.

MySQL determines the character set and collation of a character string literal, hexadecimal literal, or bit-value literal in the following manner:

- If both `_charset_name` and `COLLATE collation_name` are specified, character set `charset_name` and collation `collation_name` are used. `collation_name` must be a permitted collation for `charset_name`.
- If `_charset_name` is specified but `COLLATE` is not specified, character set `charset_name` and its default collation are used. To see the default collation for each character set, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table.
- If `_charset_name` is not specified but `COLLATE collation_name` is specified:
 - For a character string literal, the connection default character set given by the `character_set_connection` system variable and collation `collation_name` are used. `collation_name` must be a permitted collation for the connection default character set.
 - For a hexadecimal literal or bit-value literal, the only permitted collation is `binary` because these types of literals are binary strings by default.
- Otherwise (neither `_charset_name` nor `COLLATE collation_name` is specified):
 - For a character string literal, the connection default character set and collation given by the `character_set_connection` and `collation_connection` system variables are used.
 - For a hexadecimal literal or bit-value literal, the character set and collation are `binary`.

Examples:

- Nonbinary strings with `latin1` character set and `latin1_german1_ci` collation:

```
SELECT _latin1'Müller' COLLATE latin1_german1_ci;
SELECT _latin1 X'0A0D' COLLATE latin1_german1_ci;
SELECT _latin1 b'0110' COLLATE latin1_german1_ci;
```

- Nonbinary strings with `utf8mb4` character set and its default collation (that is, `utf8mb4_0900_ai_ci`):

```
SELECT _utf8mb4'Müller';
SELECT _utf8mb4 X'0A0D';
SELECT _utf8mb4 b'0110';
```

- Binary strings with `binary` character set and its default collation (that is, `binary`):

```
SELECT _binary'Müller';
SELECT X'0A0D';
SELECT b'0110';
```

The hexadecimal literal and bit-value literal need no introducer because they are binary strings by default.

- A nonbinary string with the connection default character set and `utf8mb4_general_ci` collation (fails if the connection character set is not `utf8mb4`):

```
SELECT 'Müller' COLLATE utf8mb4_general_ci;
```

This construction (`COLLATE` only) does not work for hexadecimal literals or bit literals because their character set is `binary` no matter the connection character set, and `binary` is not compatible with

the `utf8mb4_general_ci` collation. The only permitted `COLLATE` clause in the absence of an introducer is `COLLATE binary`.

- A string with the connection default character set and collation:

```
SELECT 'Müller';
```

10.3.9 Examples of Character Set and Collation Assignment

The following examples show how MySQL determines default character set and collation values.

Example 1: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1 COLLATE latin1_german1_ci
) DEFAULT CHARACTER SET latin2 COLLATE latin2_bin;
```

Here we have a column with a `latin1` character set and a `latin1_german1_ci` collation. The definition is explicit, so that is straightforward. Notice that there is no problem with storing a `latin1` column in a `latin2` table.

Example 2: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10) CHARACTER SET latin1
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

This time we have a column with a `latin1` character set and a default collation. Although it might seem natural, the default collation is not taken from the table level. Instead, because the default collation for `latin1` is always `latin1_swedish_ci`, column `c1` has a collation of `latin1_swedish_ci` (not `latin1_danish_ci`).

Example 3: Table and Column Definition

```
CREATE TABLE t1
(
  c1 CHAR(10)
) DEFAULT CHARACTER SET latin1 COLLATE latin1_danish_ci;
```

We have a column with a default character set and a default collation. In this circumstance, MySQL checks the table level to determine the column character set and collation. Consequently, the character set for column `c1` is `latin1` and its collation is `latin1_danish_ci`.

Example 4: Database, Table, and Column Definition

```
CREATE DATABASE d1
  DEFAULT CHARACTER SET latin2 COLLATE latin2_czech_ci;
USE d1;
CREATE TABLE t1
(
  c1 CHAR(10)
);
```

We create a column without specifying its character set and collation. We're also not specifying a character set and a collation at the table level. In this circumstance, MySQL checks the database level to determine the table settings, which thereafter become the column settings.) Consequently, the character set for column `c1` is `latin2` and its collation is `latin2_czech_ci`.

10.3.10 Compatibility with Other DBMSs

For MaxDB compatibility these two statements are the same:

```
CREATE TABLE t1 (f1 CHAR(N) UNICODE);
CREATE TABLE t1 (f1 CHAR(N) CHARACTER SET ucs2);
```

10.4 Connection Character Sets and Collations

A “connection” is what a client program makes when it connects to the server, to begin a session within which it interacts with the server. The client sends SQL statements, such as queries, over the session connection. The server sends responses, such as result sets or error messages, over the connection back to the client.

- [Connection Character Set and Collation System Variables](#)
- [Impermissible Client Character Sets](#)
- [Client Program Connection Character Set Configuration](#)
- [SQL Statements for Connection Character Set Configuration](#)
- [Connection Character Set Error Handling](#)

Connection Character Set and Collation System Variables

Several character set and collation system variables relate to a client's interaction with the server. Some of these have been mentioned in earlier sections:

- The `character_set_server` and `collation_server` system variables indicate the server character set and collation. See [Section 10.3.2, “Server Character Set and Collation”](#).
- The `character_set_database` and `collation_database` system variables indicate the character set and collation of the default database. See [Section 10.3.3, “Database Character Set and Collation”](#).

Additional character set and collation system variables are involved in handling traffic for the connection between a client and the server. Every client has session-specific connection-related character set and collation system variables. These session system variable values are initialized at connect time, but can be changed within the session.

Several questions about character set and collation handling for client connections can be answered in terms of system variables:

- What character set are statements in when they leave the client?

The server takes the `character_set_client` system variable to be the character set in which statements are sent by the client.

Note

Some character sets cannot be used as the client character set. See [Impermissible Client Character Sets](#).

- What character set should the server translate statements to after receiving them?

To determine this, the server uses the `character_set_connection` and `collation_connection` system variables:

- The server converts statements sent by the client from `character_set_client` to `character_set_connection`. Exception: For string literals that have an introducer such as `_utf8mb4` or `_latin2`, the introducer determines the character set. See [Section 10.3.8, “Character Set Introducers”](#).
- `collation_connection` is important for comparisons of literal strings. For comparisons of strings with column values, `collation_connection` does not matter because columns have their own collation, which has a higher collation precedence (see [Section 10.8.4, “Collation Coercibility in Expressions”](#)).

- What character set should the server translate query results to before shipping them back to the client?

The `character_set_results` system variable indicates the character set in which the server returns query results to the client. This includes result data such as column values, result metadata such as column names, and error messages.

To tell the server to perform no conversion of result sets or error messages, set `character_set_results` to `NULL` or `binary`:

```
SET character_set_results = NULL;
SET character_set_results = binary;
```

For more information about character sets and error messages, see [Section 10.6, “Error Message Character Set”](#).

To see the values of the character set and collation system variables that apply to the current session, use this statement:

```
SELECT * FROM performance_schema.session_variables
WHERE VARIABLE_NAME IN (
  'character_set_client', 'character_set_connection',
  'character_set_results', 'collation_connection'
) ORDER BY VARIABLE_NAME;
```

The following simpler statements also display the connection variables, but include other related variables as well. They can be useful to see *all* character set and collation system variables:

```
SHOW SESSION VARIABLES LIKE 'character\_set\_%';
SHOW SESSION VARIABLES LIKE 'collation\_%';
```

Clients can fine-tune the settings for these variables, or depend on the defaults (in which case, you can skip the rest of this section). If you do not use the defaults, you must change the character settings *for each connection to the server*.

Impermissible Client Character Sets

The `character_set_client` system variable cannot be set to certain character sets:

```
ucs2
utf16
utf16le
utf32
```

Attempting to use any of those character sets as the client character set produces an error:

```
mysql> SET character_set_client = 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client'
can't be set to the value of 'ucs2'
```

The same error occurs if any of those character sets are used in the following contexts, all of which result in an attempt to set `character_set_client` to the named character set:

- The `--default-character-set=charset_name` command option used by MySQL client programs such as `mysql` and `mysqladmin`.
- The `SET NAMES 'charset_name'` statement.
- The `SET CHARACTER SET 'charset_name'` statement.

Client Program Connection Character Set Configuration

When a client connects to the server, it indicates which character set it wants to use for communication with the server. (Actually, the client indicates the default collation for that character set, from which the server can determine the character set.) The server uses this information to set the

`character_set_client`, `character_set_results`, `character_set_connection` system variables to the character set, and `collation_connection` to the character set default collation. In effect, the server performs the equivalent of a `SET NAMES` operation.

If the server does not support the requested character set or collation, it falls back to using the server character set and collation to configure the connection. For additional detail about this fallback behavior, see [Connection Character Set Error Handling](#).

The `mysql`, `mysqladmin`, `mysqlcheck`, `mysqlimport`, and `mysqlshow` client programs determine the default character set to use as follows:

- In the absence of other information, each client uses the compiled-in default character set, usually `utf8mb4`.
- Each client can autodetect which character set to use based on the operating system setting, such as the value of the `LANG` or `LC_ALL` locale environment variable on Unix systems or the code page setting on Windows systems. For systems on which the locale is available from the OS, the client uses it to set the default character set rather than using the compiled-in default. For example, setting `LANG` to `ru_RU.KOI8-R` causes the `koi8r` character set to be used. Thus, users can configure the locale in their environment for use by MySQL clients.

The OS character set is mapped to the closest MySQL character set if there is no exact match. If the client does not support the matching character set, it uses the compiled-in default. For example, `utf8` and `utf-8` map to `utf8mb4`, and `ucs2` is not supported as a connection character set, so it maps to the compiled-in default.

C applications can use character set autodetection based on the OS setting by invoking `mysql_options()` as follows before connecting to the server:

```
mysql_options(mysql,
               MYSQL_SET_CHARSET_NAME,
               MYSQL_AUTODETECT_CHARSET_NAME);
```

- Each client supports a `--default-character-set` option, which enables users to specify the character set explicitly to override whatever default the client otherwise determines.

Note

Some character sets cannot be used as the client character set. Attempting to use them with `--default-character-set` produces an error. See [Impermissible Client Character Sets](#).

With the `mysql` client, to use a character set different from the default, you could explicitly execute a `SET NAMES` statement every time you connect to the server (see [Client Program Connection Character Set Configuration](#)). To accomplish the same result more easily, specify the character set in your option file. For example, the following option file setting changes the three connection-related character set system variables set to `koi8r` each time you invoke `mysql`:

```
[mysql]
default-character-set=koi8r
```

If you are using the `mysql` client with auto-reconnect enabled (which is not recommended), it is preferable to use the `charset` command rather than `SET NAMES`. For example:

```
mysql> charset koi8r
Charset changed
```

The `charset` command issues a `SET NAMES` statement, and also changes the default character set that `mysql` uses when it reconnects after the connection has dropped.

When configuring client programs, you must also consider the environment within which they execute. See [Section 10.5, “Configuring Application Character Set and Collation”](#).

SQL Statements for Connection Character Set Configuration

After a connection has been established, clients can change the character set and collation system variables for the current session. These variables can be changed individually using `SET` statements, but two more convenient statements affect the connection-related character set system variables as a group:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

`SET NAMES` indicates what character set the client will use to send SQL statements to the server. Thus, `SET NAMES 'cp1251'` tells the server, “future incoming messages from this client are in character set `cp1251`.” It also specifies the character set that the server should use for sending results back to the client. (For example, it indicates what character set to use for column values if you use a `SELECT` statement that produces a result set.)

A `SET NAMES 'charset_name'` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET character_set_connection = charset_name;
```

Setting `character_set_connection` to `charset_name` also implicitly sets `collation_connection` to the default collation for `charset_name`. It is unnecessary to set that collation explicitly. To specify a particular collation to use for `collation_connection`, add a `COLLATE` clause:

```
SET NAMES 'charset_name' COLLATE 'collation_name'
```

- `SET CHARACTER SET 'charset_name'`

`SET CHARACTER SET` is similar to `SET NAMES` but sets `character_set_connection` and `collation_connection` to `character_set_database` and `collation_database` (which, as mentioned previously, indicate the character set and collation of the default database).

A `SET CHARACTER SET charset_name` statement is equivalent to these three statements:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET collation_connection = @@collation_database;
```

Setting `collation_connection` also implicitly sets `character_set_connection` to the character set associated with the collation (equivalent to executing `SET character_set_connection = @@character_set_database`). It is unnecessary to set `character_set_connection` explicitly.

Note

Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

Example: Suppose that `column1` is defined as `CHAR(5) CHARACTER SET latin2`. If you do not say `SET NAMES` or `SET CHARACTER SET`, then for `SELECT column1 FROM t`, the server sends back all the values for `column1` using the character set that the client specified when it connected. On the other hand, if you say `SET NAMES 'latin1'` or `SET CHARACTER SET 'latin1'` before issuing the `SELECT` statement, the server converts the `latin2` values to `latin1` just before sending results back. Conversion may be lossy for characters that are not in both character sets.

Connection Character Set Error Handling

Attempts to use an inappropriate connection character set or collation can produce an error, or cause the server to fall back to its default character set and collation for a given connection. This section

describes problems that can occur when configuring the connection character set. These problems can occur when establishing a connection or when changing the character set within an established connection.

- [Connect-Time Error Handling](#)
- [Runtime Error Handling](#)

Connect-Time Error Handling

Some character sets cannot be used as the client character set; see [Impermissible Client Character Sets](#). If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
shell> mysql --default-character-set=ucs2
ERROR 1231 (42000): Variable 'character_set_client' can't be set to
the value of 'ucs2'
```

If you specify a character set that the client does not recognize, it produces an error:

```
shell> mysql --default-character-set=bogus
mysql: Character set 'bogus' is not a compiled character set and is
not specified in the '/usr/local/mysql/share/charsets/Index.xml' file
ERROR 2019 (HY000): Can't initialize character set bogus
(path: /usr/local/mysql/share/charsets/)
```

If you specify a character set that the client recognizes but the server does not, the server falls back to its default character set and collation. Suppose that the server is configured to use `latin1` and `latin1_swedish_ci` as its defaults, and that it does not recognize `gb18030` as a valid character set. A client that specifies `--default-character-set=gb18030` is able to connect to the server, but the resulting character set is not what the client wants:

```
mysql> SHOW SESSION VARIABLES LIKE 'character\_set\_%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| character_set_client | latin1 |
| character_set_connection | latin1 |
| ... |
| character_set_results | latin1 |
| ... |
+-----+-----+
mysql> SHOW SESSION VARIABLES LIKE 'collation\_connection';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| collation_connection | latin1_swedish_ci |
+-----+-----+
```

You can see that the connection system variables have been set to reflect a character set and collation of `latin1` and `latin1_swedish_ci`. This occurs because the server cannot satisfy the client character set request and falls back to its defaults.

In this case, the client cannot use the character set that it wants because the server does not support it. The client must either be willing to use a different character set, or connect to a different server that supports the desired character set.

The same problem occurs in a more subtle context: When the client tells the server to use a character set that the server recognizes, but the default collation for that character set on the client side is not known on the server side. This occurs, for example, when a MySQL 8.0 client wants to connect to a MySQL 5.7 server using `utf8mb4` as the client character set. A client that specifies `--default-character-set=utf8mb4` is able to connect to the server. However, as in the previous example, the server falls back to its default character set and collation, not what the client requested:

```
mysql> SHOW SESSION VARIABLES LIKE 'character\_set\_%';
+-----+-----+
| Variable_name | Value |
```

```
+-----+
| character_set_client | latin1 |
| character_set_connection | latin1 |
| ... |
| character_set_results | latin1 |
| ... |
+-----+
mysql> SHOW SESSION VARIABLES LIKE 'collation_connection';
+-----+
| Variable_name | Value |
+-----+
| collation_connection | latin1_swedish_ci |
+-----+
```

Why does this occur? After all, `utf8mb4` is known to the 8.0 client and the 5.7 server, so both of them recognize it. To understand this behavior, it is necessary to understand that when the client tells the server which character set it wants to use, it really tells the server the default collation for that character set. Therefore, the aforementioned behavior occurs due to a combination of factors:

- The default collation for `utf8mb4` differs between MySQL 5.7 and 8.0 (`utf8mb4_general_ci` for 5.7, `utf8mb4_0900_ai_ci` for 8.0).
- When the 8.0 client requests a character set of `utf8mb4`, what it sends to the server is the default 8.0 `utf8mb4` collation; that is, the `utf8mb4_0900_ai_ci`.
- `utf8mb4_0900_ai_ci` is implemented only as of MySQL 8.0, so the 5.7 server does not recognize it.
- Because the 5.7 server does not recognize `utf8mb4_0900_ai_ci`, it cannot satisfy the client character set request, and falls back to its default character set and collation (`latin1` and `latin1_swedish_ci`).

In this case, the client can still use `utf8mb4` by issuing a `SET NAMES 'utf8mb4'` statement after connecting. The resulting collation is the 5.7 default `utf8mb4` collation; that is, `utf8mb4_general_ci`. If the client additionally wants a collation of `utf8mb4_0900_ai_ci`, it cannot achieve that because the server does not recognize that collation. The client must either be willing to use a different `utf8mb4` collation, or connect to a server from MySQL 8.0 or higher.

Runtime Error Handling

Within an established connection, the client can request a change of connection character set and collation with `SET NAMES` or `SET CHARACTER SET`.

Some character sets cannot be used as the client character set; see [Impermissible Client Character Sets](#). If you specify a character set that is valid but not permitted as a client character set, the server returns an error:

```
mysql> SET NAMES 'ucs2';
ERROR 1231 (42000): Variable 'character_set_client' can't be set to
the value of 'ucs2'
```

If the server does not recognize the character set (or the collation), it produces an error:

```
mysql> SET NAMES 'bogus';
ERROR 1115 (42000): Unknown character set: 'bogus'

mysql> SET NAMES 'utf8mb4' COLLATE 'bogus';
ERROR 1273 (HY000): Unknown collation: 'bogus'
```

Tip

A client that wants to verify whether its requested character set was honored by the server can execute the following statement after connecting and checking that the result is the expected character set:

```
SELECT @@character_set_client;
```

10.5 Configuring Application Character Set and Collation

For applications that store data using the default MySQL character set and collation (`utf8mb4`, `utf8mb4_0900_ai_ci`), no special configuration should be needed. If applications require data storage using a different character set or collation, you can configure character set information several ways:

- Specify character settings per database. For example, applications that use one database might use the default of `utf8mb4`, whereas applications that use another database might use `sjis`.
- Specify character settings at server startup. This causes the server to use the given settings for all applications that do not make other arrangements.
- Specify character settings at configuration time, if you build MySQL from source. This causes the server to use the given settings as the defaults for all applications, without having to specify them at server startup.

When different applications require different character settings, the per-database technique provides a good deal of flexibility. If most or all applications use the same character set, specifying character settings at server startup or configuration time may be most convenient.

For the per-database or server-startup techniques, the settings control the character set for data storage. Applications must also tell the server which character set to use for client/server communications, as described in the following instructions.

The examples shown here assume use of the `latin1` character set and `latin1_swedish_ci` collation in particular contexts as an alternative to the defaults of `utf8mb4` and `utf8mb4_0900_ai_ci`.

- **Specify character settings per database.** To create a database such that its tables will use a given default character set and collation for data storage, use a `CREATE DATABASE` statement like this:

```
CREATE DATABASE mydb
  CHARACTER SET latin1
  COLLATE latin1_swedish_ci;
```

Tables created in the database will use `latin1` and `latin1_swedish_ci` by default for any character columns.

Applications that use the database should also configure their connection to the server each time they connect. This can be done by executing a `SET NAMES 'latin1'` statement after connecting. The statement can be used regardless of connection method (the `mysql` client, PHP scripts, and so forth).

In some cases, it may be possible to configure the connection to use the desired character set some other way. For example, to connect using `mysql`, you can specify the `--default-character-set=latin1` command-line option to achieve the same effect as `SET NAMES 'latin1'`.

For more information about configuring client connections, see [Section 10.4, “Connection Character Sets and Collations”](#).

Note

If you use `ALTER DATABASE` to change the database default character set or collation, existing stored routines in the database that use those defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).)

- **Specify character settings at server startup.** To select a character set and collation at server startup, use the `--character-set-server` and `--collation-server` options. For example, to specify the options in an option file, include these lines:

```
[mysqld]  
character-set-server=latin1  
collation-server=latin1_swedish_ci
```

These settings apply server-wide and apply as the defaults for databases created by any application, and for tables created in those databases.

It is still necessary for applications to configure their connection using `SET NAMES` or equivalent after they connect, as described previously. You might be tempted to start the server with the `--init_connect="SET NAMES 'latin1'"` option to cause `SET NAMES` to be executed automatically for each client that connects. However, this may yield inconsistent results because the `init_connect` value is not executed for users who have the `CONNECTION_ADMIN` privilege (or the deprecated `SUPER` privilege).

- **Specify character settings at MySQL configuration time.** To select a character set and collation if you configure and build MySQL from source, use the `DEFAULT_CHARSET` and `DEFAULT_COLLATION` CMake options:

```
cmake . -DDEFAULT_CHARSET=latin1 \  
-DDEFAULT_COLLATION=latin1_swedish_ci
```

The resulting server uses `latin1` and `latin1_swedish_ci` as the default for databases and tables and for client connections. It is unnecessary to use `--character-set-server` and `--collation-server` to specify those defaults at server startup. It is also unnecessary for applications to configure their connection using `SET NAMES` or equivalent after they connect to the server.

Regardless of how you configure the MySQL character set for application use, you must also consider the environment within which those applications execute. For example, if you will send statements using UTF-8 text taken from a file that you create in an editor, you should edit the file with the locale of your environment set to UTF-8 so that the file encoding is correct and so that the operating system handles it correctly. If you use the `mysql` client from within a terminal window, the window must be configured to use UTF-8 or characters may not display properly. For a script that executes in a Web environment, the script must handle character encoding properly for its interaction with the MySQL server, and it must generate pages that correctly indicate the encoding so that browsers know how to display the content of the pages. For example, you can include this `<meta>` tag within your `<head>` element:

```
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
```

10.6 Error Message Character Set

This section describes how the MySQL server uses character sets for constructing error messages. For information about the language of error messages (rather than the character set), see [Section 10.12, “Setting the Error Message Language”](#). For general information about configuring error logging, see [Section 5.4.2, “The Error Log”](#).

- [Character Set for Error Message Construction](#)
- [Character Set for Error Message Disposition](#)

Character Set for Error Message Construction

The server constructs error messages as follows:

- The message template uses UTF-8 (`utf8mb3`).

- Parameters in the message template are replaced with values that apply to a specific error occurrence:
 - Identifiers such as table or column names use UTF-8 internally so they are copied as is.
 - Character (nonbinary) string values are converted from their character set to UTF-8.
 - Binary string values are copied as is for bytes in the range 0x20 to 0x7E, and using \x hexadecimal encoding for bytes outside that range. For example, if a duplicate-key error occurs for an attempt to insert 0x41CF9F into a VARBINARY unique column, the resulting error message uses UTF-8 with some bytes hexadecimal encoded:

```
Duplicate entry 'A\xC3\x9F' for key 1
```

Character Set for Error Message Disposition

An error message, once constructed, can be written by the server to the error log or sent to clients:

- If the server writes the error message to the error log, it writes it in UTF-8, as constructed, without conversion to another character set.
- If the server sends the error message to a client program, the server converts it from UTF-8 to the character set specified by the `character_set_results` system variable. If `character_set_results` has a value of `NULL` or `binary`, no conversion occurs. No conversion occurs if the variable value is `utf8mb3` or `utf8mb4`, either, because those character sets have a repertoire that includes all UTF-8 characters used in message construction.

If characters cannot be represented in `character_set_results`, some encoding may occur during the conversion. The encoding uses Unicode code point values:

- Characters in the Basic Multilingual Plane (BMP) range (0x0000 to 0xFFFF) are written using \nnnn notation.
- Characters outside the BMP range (0x10000 to 0x10FFFF) are written using \+nnnnnn notation.

Clients can set `character_set_results` to control the character set in which they receive error messages. The variable can be set directly, or indirectly by means such as `SET NAMES`. For more information about `character_set_results`, see [Section 10.4, “Connection Character Sets and Collations”](#).

10.7 Column Character Set Conversion

To convert a binary or nonbinary string column to use a particular character set, use `ALTER TABLE`. For successful conversion to occur, one of the following conditions must apply:

- If the column has a binary data type (`BINARY`, `VARBINARY`, `BLOB`), all the values that it contains must be encoded using a single character set (the character set you're converting the column to). If you use a binary column to store information in multiple character sets, MySQL has no way to know which values use which character set and cannot convert the data properly.
- If the column has a nonbinary data type (`CHAR`, `VARCHAR`, `TEXT`), its contents should be encoded in the column character set, not some other character set. If the contents are encoded in a different character set, you can convert the column to use a binary data type first, and then to a nonbinary column with the desired character set.

Suppose that a table `t` has a binary column named `col1` defined as `VARBINARY(50)`. Assuming that the information in the column is encoded using a single character set, you can convert it to a nonbinary column that has that character set. For example, if `col1` contains binary data representing characters in the `greek` character set, you can convert it as follows:

```
ALTER TABLE t MODIFY col1 VARCHAR(50) CHARACTER SET greek;
```

If your original column has a type of `BINARY(50)`, you could convert it to `CHAR(50)`, but the resulting values will be padded with `0x00` bytes at the end, which may be undesirable. To remove these bytes, use the `TRIM()` function:

```
UPDATE t SET coll = TRIM(TRAILING 0x00 FROM coll);
```

Suppose that table `t` has a nonbinary column named `coll` defined as `CHAR(50) CHARACTER SET latin1` but you want to convert it to use `utf8` so that you can store values from many languages. The following statement accomplishes this:

```
ALTER TABLE t MODIFY coll CHAR(50) CHARACTER SET utf8;
```

Conversion may be lossy if the column contains characters that are not in both character sets.

A special case occurs if you have old tables from before MySQL 4.1 where a nonbinary column contains values that actually are encoded in a character set different from the server's default character set. For example, an application might have stored `sjis` values in a column, even though MySQL's default character set was different. It is possible to convert the column to use the proper character set but an additional step is required. Suppose that the server's default character set was `latin1` and `coll` is defined as `CHAR(50)` but its contents are `sjis` values. The first step is to convert the column to a binary data type, which removes the existing character set information without performing any character conversion:

```
ALTER TABLE t MODIFY coll BLOB;
```

The next step is to convert the column to a nonbinary data type with the proper character set:

```
ALTER TABLE t MODIFY coll CHAR(50) CHARACTER SET sjis;
```

This procedure requires that the table not have been modified already with statements such as `INSERT` or `UPDATE` after an upgrade to MySQL 4.1 or higher. In that case, MySQL would store new values in the column using `latin1`, and the column will contain a mix of `sjis` and `latin1` values and cannot be converted properly.

If you specified attributes when creating a column initially, you should also specify them when altering the table with `ALTER TABLE`. For example, if you specified `NOT NULL` and an explicit `DEFAULT` value, you should also provide them in the `ALTER TABLE` statement. Otherwise, the resulting column definition will not include those attributes.

To convert all character columns in a table, the `ALTER TABLE ... CONVERT TO CHARACTER SET charset` statement may be useful. See [Section 13.1.9, "ALTER TABLE Statement"](#).

10.8 Collation Issues

The following sections discuss various aspects of character set collations.

10.8.1 Using COLLATE in SQL Statements

With the `COLLATE` clause, you can override whatever the default collation is for a comparison. `COLLATE` may be used in various parts of SQL statements. Here are some examples:

- With `ORDER BY`:

```
SELECT k
FROM t1
ORDER BY k COLLATE latin1_german2_ci;
```

- With `AS`:

```
SELECT k COLLATE latin1_german2_ci AS k1
FROM t1
ORDER BY k1;
```

- With `GROUP BY`:

```
SELECT k
FROM t1
GROUP BY k COLLATE latin1_german2_ci;
```

- With aggregate functions:

```
SELECT MAX(k COLLATE latin1_german2_ci)
FROM t1;
```

- With **DISTINCT**:

```
SELECT DISTINCT k COLLATE latin1_german2_ci
FROM t1;
```

- With **WHERE**:

```
SELECT *
FROM t1
WHERE _latin1 'Müller' COLLATE latin1_german2_ci = k;
```

```
SELECT *
FROM t1
WHERE k LIKE _latin1 'Müller' COLLATE latin1_german2_ci;
```

- With **HAVING**:

```
SELECT k
FROM t1
GROUP BY k
HAVING k = _latin1 'Müller' COLLATE latin1_german2_ci;
```

10.8.2 COLLATE Clause Precedence

The **COLLATE** clause has high precedence (higher than `||`), so the following two expressions are equivalent:

```
x || y COLLATE z
x || (y COLLATE z)
```

10.8.3 Character Set and Collation Compatibility

Each character set has one or more collations, but each collation is associated with one and only one character set. Therefore, the following statement causes an error message because the **latin2_bin** collation is not legal with the **latin1** character set:

```
mysql> SELECT _latin1 'x' COLLATE latin2_bin;
ERROR 1253 (42000): COLLATION 'latin2_bin' is not valid
for CHARACTER SET 'latin1'
```

10.8.4 Collation Coercibility in Expressions

In the great majority of statements, it is obvious what collation MySQL uses to resolve a comparison operation. For example, in the following cases, it should be clear that the collation is the collation of column **x**:

```
SELECT x FROM T ORDER BY x;
SELECT x FROM T WHERE x = x;
SELECT DISTINCT x FROM T;
```

However, with multiple operands, there can be ambiguity. For example, this statement performs a comparison between the column **x** and the string literal **'Y'**:

```
SELECT x FROM T WHERE x = 'Y';
```

If **x** and **'Y'** have the same collation, there is no ambiguity about the collation to use for the comparison. But if they have different collations, should the comparison use the collation of **x**, or of **'Y'**? Both **x** and **'Y'** have collations, so which collation takes precedence?

A mix of collations may also occur in contexts other than comparison. For example, a multiple-argument concatenation operation such as `CONCAT(x, 'Y')` combines its arguments to produce a single string. What collation should the result have?

To resolve questions like these, MySQL checks whether the collation of one item can be coerced to the collation of the other. MySQL assigns coercibility values as follows:

- An explicit `COLLATE` clause has a coercibility of 0 (not coercible at all).
- The concatenation of two strings with different collations has a coercibility of 1.
- The collation of a column or a stored routine parameter or local variable has a coercibility of 2.
- A “system constant” (the string returned by functions such as `USER()` or `VERSION()`) has a coercibility of 3.
- The collation of a literal has a coercibility of 4.
- The collation of a numeric or temporal value has a coercibility of 5.
- `NULL` or an expression that is derived from `NULL` has a coercibility of 6.

MySQL uses coercibility values with the following rules to resolve ambiguities:

- Use the collation with the lowest coercibility value.
- If both sides have the same coercibility, then:
 - If both sides are Unicode, or both sides are not Unicode, it is an error.
 - If one of the sides has a Unicode character set, and another side has a non-Unicode character set, the side with Unicode character set wins, and automatic character set conversion is applied to the non-Unicode side. For example, the following statement does not return an error:

```
SELECT CONCAT(utf8mb4_column, latin1_column) FROM t1;
```

It returns a result that has a character set of `utf8mb4` and the same collation as `utf8mb4_column`. Values of `latin1_column` are automatically converted to `utf8mb4` before concatenating.

- For an operation with operands from the same character set but that mix a `_bin` collation and a `_ci` or `_cs` collation, the `_bin` collation is used. This is similar to how operations that mix nonbinary and binary strings evaluate the operands as binary strings, applied to collations rather than data types.

Although automatic conversion is not in the SQL standard, the standard does say that every character set is (in terms of supported characters) a “subset” of Unicode. Because it is a well-known principle that “what applies to a superset can apply to a subset,” we believe that a collation for Unicode can apply for comparisons with non-Unicode strings. More generally, MySQL uses the concept of character set repertoire, which can sometimes be used to determine subset relationships among character sets and enable conversion of operands in operations that would otherwise produce an error. See [Section 10.2.1, “Character Set Repertoire”](#).

The following table illustrates some applications of the preceding rules.

Comparison	Collation Used
<code>column1 = 'A'</code>	Use collation of <code>column1</code>
<code>column1 = 'A' COLLATE x</code>	Use collation of <code>'A' COLLATE x</code>
<code>column1 COLLATE x = 'A' COLLATE y</code>	Error

To determine the coercibility of a string expression, use the `COERCIBILITY()` function (see [Section 12.16, “Information Functions”](#)):

```
mysql> SELECT COERCIBILITY(_utf8'A' COLLATE utf8_bin);
-> 0
mysql> SELECT COERCIBILITY(VERSION());
-> 3
mysql> SELECT COERCIBILITY('A');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
mysql> SELECT COERCIBILITY(NULL);
-> 6
```

For implicit conversion of a numeric or temporal value to a string, such as occurs for the argument `1` in the expression `CONCAT(1, 'abc')`, the result is a character (nonbinary) string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. See [Section 12.3, “Type Conversion in Expression Evaluation”](#).

10.8.5 The binary Collation Compared to `_bin` Collations

This section describes how the `binary` collation for binary strings compares to `_bin` collations for nonbinary strings.

Binary strings (as stored using the `BINARY`, `VARBINARY`, and `BLOB` data types) have a character set and collation named `binary`. Binary strings are sequences of bytes and the numeric values of those bytes determine comparison and sort order. See [Section 10.10.8, “The Binary Character Set”](#).

Nonbinary strings (as stored using the `CHAR`, `VARCHAR`, and `TEXT` data types) have a character set and collation other than `binary`. A given nonbinary character set can have several collations, each of which defines a particular comparison and sort order for the characters in the set. For most character sets, one of these is the binary collation, indicated by a `_bin` suffix in the collation name. For example, the binary collation for `utf8` and `latin1` is named `utf8_bin` and `latin1_bin`, respectively. `utf8mb4` is an exception that has two binary collations, `utf8mb4_bin` and `utf8mb4_0900_bin`; see [Section 10.10.1, “Unicode Character Sets”](#).

The `binary` collation differs from `_bin` collations in several respects, discussed in the following sections:

- [The Unit for Comparison and Sorting](#)
- [Character Set Conversion](#)
- [Lettercase Conversion](#)
- [Trailing Space Handling in Comparisons](#)
- [Trailing Space Handling for Inserts and Retrievals](#)

The Unit for Comparison and Sorting

Binary strings are sequences of bytes. For the `binary` collation, comparison and sorting are based on numeric byte values. Nonbinary strings are sequences of characters, which might be multibyte. Collations for nonbinary strings define an ordering of the character values for comparison and sorting. For `_bin` collations, this ordering is based on numeric character code values, which is similar to ordering for binary strings except that character code values might be multibyte.

Character Set Conversion

A nonbinary string has a character set and is automatically converted to another character set in many cases, even when the string has a `_bin` collation:

- When assigning column values to another column that has a different character set:

```
UPDATE t1 SET utf8_bin_column=latin1_column;
INSERT INTO t1 (latin1_column) SELECT utf8_bin_column FROM t2;
```

- When assigning column values for `INSERT` or `UPDATE` using a string literal:

```
SET NAMES latin1;
INSERT INTO t1 (utf8_bin_column) VALUES ('string-in-latin1');
```

- When sending results from the server to a client:

```
SET NAMES latin1;
SELECT utf8_bin_column FROM t2;
```

For binary string columns, no conversion occurs. For cases similar to those preceding, the string value is copied byte-wise.

Lettercase Conversion

Collations for nonbinary character sets provide information about lettercase of characters, so characters in a nonbinary string can be converted from one lettercase to another, even for `_bin` collations that ignore lettercase for ordering:

```
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT LOWER('aA'), UPPER('zZ');
+-----+-----+
| LOWER('aA') | UPPER('zZ') |
+-----+-----+
| aa          | ZZ          |
+-----+-----+
```

The concept of lettercase does not apply to bytes in a binary string. To perform lettercase conversion, the string must first be converted to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET NAMES binary;
mysql> SELECT LOWER('aA'), LOWER(CONVERT('aA' USING utf8mb4));
+-----+-----+
| LOWER('aA') | LOWER(CONVERT('aA' USING utf8mb4)) |
+-----+-----+
| aA          | aa          |
+-----+-----+
```

Trailing Space Handling in Comparisons

MySQL collations have a pad attribute, which has a value of `PAD SPACE` or `NO PAD`:

- Most MySQL collations have a pad attribute of `PAD SPACE`.
- The Unicode collations based on UCA 9.0.0 and higher have a pad attribute of `NO PAD`; see [Section 10.10.1, “Unicode Character Sets”](#).

For nonbinary strings (`CHAR`, `VARCHAR`, and `TEXT` values), the string collation pad attribute determines treatment in comparisons of trailing spaces at the end of strings:

- For `PAD SPACE` collations, trailing spaces are insignificant in comparisons; strings are compared without regard to trailing spaces.
- `NO PAD` collations treat trailing spaces as significant in comparisons, like any other character.

The differing behaviors can be demonstrated using the two `utf8mb4` binary collations, one of which is `PAD SPACE`, the other of which is `NO PAD`. The example also shows how to use the `INFORMATION_SCHEMA.COLLATIONS` table to determine the pad attribute for collations.

```
mysql> SELECT COLLATION_NAME, PAD_ATTRIBUTE
FROM INFORMATION_SCHEMA.COLLATIONS
WHERE COLLATION_NAME LIKE 'utf8mb4%bin';
+-----+-----+
| COLLATION_NAME | PAD_ATTRIBUTE |
+-----+-----+
| utf8mb4_bin    | PAD SPACE    |
| utf8mb4_0900_bin | NO PAD       |
+-----+-----+
```

```

+-----+
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_bin;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
|          1 |
+-----+
mysql> SET NAMES utf8mb4 COLLATE utf8mb4_0900_bin;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
|          0 |
+-----+

```

**Note**

“Comparison” in this context does not include the [LIKE](#) pattern-matching operator, for which trailing spaces are significant, regardless of collation.

For binary strings ([BINARY](#), [VARBINARY](#), and [BLOB](#) values), all bytes are significant in comparisons, including trailing spaces:

```

mysql> SET NAMES binary;
mysql> SELECT 'a ' = 'a';
+-----+
| 'a ' = 'a' |
+-----+
|          0 |
+-----+

```

Trailing Space Handling for Inserts and Retrievals

[CHAR\(N\)](#) columns store nonbinary strings *N* characters long. For inserts, values shorter than *N* characters are extended with spaces. For retrievals, trailing spaces are removed.

[BINARY\(N\)](#) columns store binary strings *N* bytes long. For inserts, values shorter than *N* bytes are extended with `0x00` bytes. For retrievals, nothing is removed; a value of the declared length is always returned.

```

mysql> CREATE TABLE t1 (
    a CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin,
    b BINARY(10)
);
mysql> INSERT INTO t1 VALUES ('x','x');
mysql> INSERT INTO t1 VALUES ('x ','x ');
mysql> SELECT a, b, HEX(a), HEX(b) FROM t1;
+-----+-----+-----+-----+
| a      | b      | HEX(a) | HEX(b) |
+-----+-----+-----+-----+
| x      | x      | 78     | 78000000000000000000 |
| x      | x      | 78     | 78200000000000000000 |
+-----+-----+-----+-----+

```

10.8.6 Examples of the Effect of Collation

Example 1: Sorting German Umlauts

Suppose that column *X* in table *T* has these [latin1](#) column values:

```

Muffler
Müller
MX Systems
MySQL

```

Suppose also that the column values are retrieved using the following statement:

```
SELECT X FROM T ORDER BY X COLLATE collation_name;
```

The following table shows the resulting order of the values if we use `ORDER BY` with different collations.

<code>latin1_swedish_ci</code>	<code>latin1_german1_ci</code>	<code>latin1_german2_ci</code>
Muffler	Muffler	Müller
MX Systems	Müller	Muffler
Müller	MX Systems	MX Systems
MySQL	MySQL	MySQL

The character that causes the different sort orders in this example is the U with two dots over it (ü), which the Germans call “U-umlaut.”

- The first column shows the result of the `SELECT` using the Swedish/Finnish collating rule, which says that U-umlaut sorts with Y.
- The second column shows the result of the `SELECT` using the German DIN-1 rule, which says that U-umlaut sorts with U.
- The third column shows the result of the `SELECT` using the German DIN-2 rule, which says that U-umlaut sorts with UE.

Example 2: Searching for German Umlauts

Suppose that you have three tables that differ only by the character set and collation used:

```
mysql> SET NAMES utf8;
mysql> CREATE TABLE german1 (
    c CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_german1_ci;
mysql> CREATE TABLE german2 (
    c CHAR(10)
) CHARACTER SET latin1 COLLATE latin1_german2_ci;
mysql> CREATE TABLE germanutf8 (
    c CHAR(10)
) CHARACTER SET utf8 COLLATE utf8_unicode_ci;
```

Each table contains two records:

```
mysql> INSERT INTO german1 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO german2 VALUES ('Bar'), ('Bär');
mysql> INSERT INTO germanutf8 VALUES ('Bar'), ('Bär');
```

Two of the above collations have an `A = Ä` equality, and one has no such equality (`latin1_german2_ci`). For that reason, you'll get these results in comparisons:

```
mysql> SELECT * FROM german1 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bar    |
| Bär    |
+-----+
mysql> SELECT * FROM german2 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bär    |
+-----+
mysql> SELECT * FROM germanutf8 WHERE c = 'Bär';
+-----+
| c      |
+-----+
| Bar    |
| Bär    |
+-----+
```

This is not a bug but rather a consequence of the sorting properties of `latin1_german1_ci` and `utf8_unicode_ci` (the sorting shown is done according to the German DIN 5007 standard).

10.8.7 Using Collation in INFORMATION_SCHEMA Searches

String columns in `INFORMATION_SCHEMA` tables have a collation of `utf8_general_ci`, which is case-insensitive. However, for values that correspond to objects that are represented in the file system, such as databases and tables, searches in `INFORMATION_SCHEMA` string columns can be case-sensitive or case-insensitive, depending on the characteristics of the underlying file system and the `lower_case_table_names` system variable setting. For example, searches may be case-sensitive if the file system is case-sensitive. This section describes this behavior and how to modify it if necessary.

Suppose that a query searches the `SCHEMATA.SCHEMA_NAME` column for the `test` database. On Linux, file systems are case-sensitive, so comparisons of `SCHEMATA.SCHEMA_NAME` with `'test'` match, but comparisons with `'TEST'` do not:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      WHERE SCHEMA_NAME = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      WHERE SCHEMA_NAME = 'TEST';
Empty set (0.00 sec)
```

These results occur with the `lower_case_table_names` system variable set to 0. A `lower_case_table_names` setting of 1 or 2 causes the second query to return the same (nonempty) result as the first query.

Note

It is prohibited to start the server with a `lower_case_table_names` setting that is different from the setting used when the server was initialized.

On Windows or macOS, file systems are not case-sensitive, so comparisons match both `'test'` and `'TEST'`:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      WHERE SCHEMA_NAME = 'test';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      WHERE SCHEMA_NAME = 'TEST';
+-----+
| SCHEMA_NAME |
+-----+
| TEST        |
+-----+
```

The value of `lower_case_table_names` makes no difference in this context.

The preceding behavior occurs because the `utf8_general_ci` collation is not used for `INFORMATION_SCHEMA` queries when searching for values that correspond to objects represented in the file system.

If the result of a string operation on an `INFORMATION_SCHEMA` column differs from expectations, a workaround is to use an explicit `COLLATE` clause to force a suitable collation (see [Section 10.8.1, “Using COLLATE in SQL Statements”](#)). For example, to perform a case-insensitive search, use `COLLATE` with the `INFORMATION_SCHEMA` column name:

```
mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
      WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'test';
+-----+
```

```

+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
       WHERE SCHEMA_NAME COLLATE utf8_general_ci = 'TEST';
+-----+
| SCHEMA_NAME |
+-----+
| test        |
+-----+

```

You can also use the `UPPER()` or `LOWER()` function:

```

WHERE UPPER(SCHEMA_NAME) = 'TEST'
WHERE LOWER(SCHEMA_NAME) = 'test'

```

Although a case-insensitive comparison can be performed even on platforms with case-sensitive file systems, as just shown, it is not necessarily always the right thing to do. On such platforms, it is possible to have multiple objects with names that differ only in lettercase. For example, tables named `city`, `CITY`, and `City` can all exist simultaneously. Consider whether a search should match all such names or just one and write queries accordingly. The first of the following comparisons (with `utf8_bin`) is case-sensitive; the others are not:

```

WHERE TABLE_NAME COLLATE utf8_bin = 'City'
WHERE TABLE_NAME COLLATE utf8_general_ci = 'city'
WHERE UPPER(TABLE_NAME) = 'CITY'
WHERE LOWER(TABLE_NAME) = 'city'

```

Searches in `INFORMATION_SCHEMA` string columns for values that refer to `INFORMATION_SCHEMA` itself do use the `utf8_general_ci` collation because `INFORMATION_SCHEMA` is a “virtual” database not represented in the file system. For example, comparisons with `SCHEMATA.SCHEMA_NAME` match `'information_schema'` or `'INFORMATION_SCHEMA'` regardless of platform:

```

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
       WHERE SCHEMA_NAME = 'information_schema';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+

mysql> SELECT SCHEMA_NAME FROM INFORMATION_SCHEMA.SCHEMATA
       WHERE SCHEMA_NAME = 'INFORMATION_SCHEMA';
+-----+
| SCHEMA_NAME |
+-----+
| information_schema |
+-----+

```

10.9 Unicode Support

The Unicode Standard includes characters from the Basic Multilingual Plane (BMP) and supplementary characters that lie outside the BMP. This section describes support for Unicode in MySQL. For information about the Unicode Standard itself, visit the [Unicode Consortium website](#).

BMP characters have these characteristics:

- Their code point values are between 0 and 65535 (or `U+0000` and `U+FFFF`).
- They can be encoded in a variable-length encoding using 8, 16, or 24 bits (1 to 3 bytes).
- They can be encoded in a fixed-length encoding using 16 bits (2 bytes).
- They are sufficient for almost all characters in major languages.

Supplementary characters lie outside the BMP:

- Their code point values are between `U+10000` and `U+10FFFF`).
- Unicode support for supplementary characters requires character sets that have a range outside BMP characters and therefore take more space than BMP characters (up to 4 bytes per character).

The UTF-8 (Unicode Transformation Format with 8-bit units) method for encoding Unicode data is implemented according to RFC 3629, which describes encoding sequences that take from one to four bytes. The idea of UTF-8 is that various Unicode characters are encoded using byte sequences of different lengths:

- Basic Latin letters, digits, and punctuation signs use one byte.
- Most European and Middle East script letters fit into a 2-byte sequence: extended Latin letters (with tilde, macron, acute, grave and other accents), Cyrillic, Greek, Armenian, Hebrew, Arabic, Syriac, and others.
- Korean, Chinese, and Japanese ideographs use 3-byte or 4-byte sequences.

MySQL supports these Unicode character sets:

- `utf8mb4`: A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- `utf8mb3`: A UTF-8 encoding of the Unicode character set using one to three bytes per character.
- `utf8`: An alias for `utf8mb3`.
- `ucs2`: The UCS-2 encoding of the Unicode character set using two bytes per character.
- `utf16`: The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like `ucs2` but with an extension for supplementary characters.
- `utf16le`: The UTF-16LE encoding for the Unicode character set. Like `utf16` but little-endian rather than big-endian.
- `utf32`: The UTF-32 encoding for the Unicode character set using four bytes per character.

Note

The `utf8mb3` character set is deprecated and will be removed in a future MySQL release. Please use `utf8mb4` instead. Although `utf8` is currently an alias for `utf8mb3`, at some point `utf8` will become a reference to `utf8mb4`. To avoid ambiguity about the meaning of `utf8`, consider specifying `utf8mb4` explicitly for character set references instead of `utf8`.

Table 10.2, “Unicode Character Set General Characteristics”, summarizes the general characteristics of Unicode character sets supported by MySQL.

Table 10.2 Unicode Character Set General Characteristics

Character Set	Supported Characters	Required Storage Per Character
<code>utf8mb3</code> , <code>utf8</code>	BMP only	1, 2, or 3 bytes
<code>ucs2</code>	BMP only	2 bytes
<code>utf8mb4</code>	BMP and supplementary	1, 2, 3, or 4 bytes
<code>utf16</code>	BMP and supplementary	2 or 4 bytes
<code>utf16le</code>	BMP and supplementary	2 or 4 bytes
<code>utf32</code>	BMP and supplementary	4 bytes

Characters outside the BMP compare as REPLACEMENT CHARACTER and convert to `'?'` when converted to a Unicode character set that supports only BMP characters (`utf8mb3` or `ucs2`).

If you use character sets that support supplementary characters and thus are “wider” than the BMP-only `utf8mb3` and `ucs2` character sets, there are potential incompatibility issues for your applications;

see [Section 10.9.8, “Converting Between 3-Byte and 4-Byte Unicode Character Sets”](#). That section also describes how to convert tables from the (3-byte) `utf8mb3` to the (4-byte) `utf8mb4`, and what constraints may apply in doing so.

A similar set of collations is available for most Unicode character sets. For example, each has a Danish collation, the names of which are `utf8mb4_danish_ci`, `utf8mb3_danish_ci`, `utf8_danish_ci`, `ucs2_danish_ci`, `utf16_danish_ci`, and `utf32_danish_ci`. The exception is `utf16le`, which has only two collations. For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see [Section 10.10.1, “Unicode Character Sets”](#).

The MySQL implementation of UCS-2, UTF-16, and UTF-32 stores characters in big-endian byte order and does not use a byte order mark (BOM) at the beginning of values. Other database systems might use little-endian byte order or a BOM. In such cases, conversion of values will need to be performed when transferring data between those systems and MySQL. The implementation of UTF-16LE is little-endian.

MySQL uses no BOM for UTF-8 values.

Client applications that communicate with the server using Unicode should set the client character set accordingly (for example, by issuing a `SET NAMES 'utf8mb4'` statement). Some character sets cannot be used as the client character set. Attempting to use them with `SET NAMES` or `SET CHARACTER SET` produces an error. See [Impermissible Client Character Sets](#).

The following sections provide additional detail on the Unicode character sets in MySQL.

10.9.1 The utf8mb4 Character Set (4-Byte UTF-8 Unicode Encoding)

The `utfmb4` character set has these characteristics:

- Supports BMP and supplementary characters.
- Requires a maximum of four bytes per multibyte character.

`utf8mb4` contrasts with the `utf8mb3` character set, which supports only BMP characters and uses a maximum of three bytes per character:

- For a BMP character, `utf8mb4` and `utf8mb3` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8mb4` requires four bytes to store it, whereas `utf8mb3` cannot store the character at all. When converting `utf8mb3` columns to `utf8mb4`, you need not worry about converting supplementary characters because there will be none.

`utf8mb4` is a superset of `utf8mb3`, so for an operation such as the following concatenation, the result has character set `utf8mb4` and the collation of `utf8mb4_col`:

```
SELECT CONCAT(utf8mb3_col, utf8mb4_col);
```

Similarly, the following comparison in the `WHERE` clause works according to the collation of `utf8mb4_col`:

```
SELECT * FROM utf8mb3_tbl, utf8mb4_tbl
WHERE utf8mb3_tbl.utf8mb3_col = utf8mb4_tbl.utf8mb4_col;
```

For information about data type storage as it relates to multibyte character sets, see [String Type Storage Requirements](#).

10.9.2 The utf8mb3 Character Set (3-Byte UTF-8 Unicode Encoding)

The `utf8mb3` character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)

- Requires a maximum of three bytes per multibyte character.

Applications that use UTF-8 data but require supplementary character support should use `utf8mb4` rather than `utf8mb3` (see [Section 10.9.1, “The utf8mb4 Character Set \(4-Byte UTF-8 Unicode Encoding\)”](#)).

Exactly the same set of characters is available in `utf8mb3` and `ucs2`. That is, they have the same repertoire.

`utf8` is an alias for `utf8mb3`; the character limit is implicit, rather than explicit in the name.

Note

The `utf8mb3` character set is deprecated and will be removed in a future MySQL release. Please use `utf8mb4` instead. Although `utf8` is currently an alias for `utf8mb3`, at some point `utf8` will become a reference to `utf8mb4`. To avoid ambiguity about the meaning of `utf8`, consider specifying `utf8mb4` explicitly for character set references instead of `utf8`.

`utf8mb3` can be used in `CHARACTER SET` clauses, and `utf8mb3_collation_substring` in `COLLATE` clauses, where `collation_substring` is `bin`, `czech_ci`, `danish_ci`, `esperanto_ci`, `estonian_ci`, and so forth. For example:

```
CREATE TABLE t (s1 CHAR(1) CHARACTER SET utf8mb3;
SELECT * FROM t WHERE s1 COLLATE utf8mb3_general_ci = 'x';
DECLARE x VARCHAR(5) CHARACTER SET utf8mb3 COLLATE utf8mb3_danish_ci;
SELECT CAST('a' AS CHAR CHARACTER SET utf8) COLLATE utf8_czech_ci;
```

MySQL immediately converts instances of `utf8mb3` in statements to `utf8`, so in statements such as `SHOW CREATE TABLE` or `SELECT CHARACTER_SET_NAME FROM INFORMATION_SCHEMA.COLUMNS` or `SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLUMNS`, users will see the name `utf8` or `utf8_collation_substring`.

`utf8mb3` is also valid in contexts other than `CHARACTER SET` clauses. For example:

```
mysql --character-set-server=utf8mb3
```

```
SET NAMES 'utf8mb3'; /* and other SET statements that have similar effect */
SELECT _utf8mb3 'a';
```

For information about data type storage as it relates to multibyte character sets, see [String Type Storage Requirements](#).

10.9.3 The utf8 Character Set (Alias for utf8mb3)

`utf8` is an alias for the `utf8mb3` character set. For more information, see [Section 10.9.2, “The utf8mb3 Character Set \(3-Byte UTF-8 Unicode Encoding\)”](#).

Note

The `utf8mb3` character set is deprecated and will be removed in a future MySQL release. Please use `utf8mb4` instead. Although `utf8` is currently an alias for `utf8mb3`, at some point `utf8` will become a reference to `utf8mb4`. To avoid ambiguity about the meaning of `utf8`, consider specifying `utf8mb4` explicitly for character set references instead of `utf8`.

10.9.4 The ucs2 Character Set (UCS-2 Unicode Encoding)

In UCS-2, every character is represented by a 2-byte Unicode code with the most significant byte first. For example: `LATIN CAPITAL LETTER A` has the code `0x0041` and it is stored as a 2-byte sequence: `0x00 0x41`. `CYRILLIC SMALL LETTER YERU` (Unicode `0x044B`) is stored as a 2-byte sequence: `0x04 0x4B`. For Unicode characters and their codes, please refer to the [Unicode Consortium website](#).

The `ucs2` character set has these characteristics:

- Supports BMP characters only (no support for supplementary characters)
- Uses a fixed-length 16-bit encoding and requires two bytes per character.

10.9.5 The utf16 Character Set (UTF-16 Unicode Encoding)

The `utf16` character set is the `ucs2` character set with an extension that enables encoding of supplementary characters:

- For a BMP character, `utf16` and `ucs2` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf16` has a special sequence for representing the character using 32 bits. This is called the “surrogate” mechanism: For a number greater than `0xffff`, take 10 bits and add them to `0xd800` and put them in the first 16-bit word, take 10 more bits and add them to `0xdc00` and put them in the next 16-bit word. Consequently, all supplementary characters require 32 bits, where the first 16 bits are a number between `0xd800` and `0xdbff`, and the last 16 bits are a number between `0xdc00` and `0xdfff`. Examples are in Section 15.5 [Surrogates Area](#) of the Unicode 4.0 document.

Because `utf16` supports surrogates and `ucs2` does not, there is a validity check that applies only in `utf16`: You cannot insert a top surrogate without a bottom surrogate, or vice versa. For example:

```
INSERT INTO t (ucs2_column) VALUES (0xd800); /* legal */
INSERT INTO t (utf16_column)VALUES (0xd800); /* illegal */
```

There is no validity check for characters that are technically valid but are not true Unicode (that is, characters that Unicode considers to be “unassigned code points” or “private use” characters or even “illegals” like `0xffff`). For example, since `U+F8FF` is the Apple Logo, this is legal:

```
INSERT INTO t (utf16_column)VALUES (0xf8ff); /* legal */
```

Such characters cannot be expected to mean the same thing to everyone.

Because MySQL must allow for the worst case (that one character requires four bytes) the maximum length of a `utf16` column or index is only half of the maximum length for a `ucs2` column or index. For example, the maximum length of a `MEMORY` table index key is 3072 bytes, so these statements create tables with the longest permitted indexes for `ucs2` and `utf16` columns:

```
CREATE TABLE tf (s1 VARCHAR(1536) CHARACTER SET ucs2) ENGINE=MEMORY;
CREATE INDEX i ON tf (s1);
CREATE TABLE tg (s1 VARCHAR(768) CHARACTER SET utf16) ENGINE=MEMORY;
CREATE INDEX i ON tg (s1);
```

10.9.6 The utf16le Character Set (UTF-16LE Unicode Encoding)

This is the same as `utf16` but is little-endian rather than big-endian.

10.9.7 The utf32 Character Set (UTF-32 Unicode Encoding)

The `utf32` character set is fixed length (like `ucs2` and unlike `utf16`). `utf32` uses 32 bits for every character, unlike `ucs2` (which uses 16 bits for every character), and unlike `utf16` (which uses 16 bits for some characters and 32 bits for others).

`utf32` takes twice as much space as `ucs2` and more space than `utf16`, but `utf32` has the same advantage as `ucs2` that it is predictable for storage: The required number of bytes for `utf32` equals the number of characters times 4. Also, unlike `utf16`, there are no tricks for encoding in `utf32`, so the stored value equals the code value.

To demonstrate how the latter advantage is useful, here is an example that shows how to determine a `utf8mb4` value given the `utf32` code value:

```
/* Assume code value = 100cc LINEAR B WHEELED CHARIOT */
CREATE TABLE tmp (utf32_col CHAR(1) CHARACTER SET utf32,
                   utf8mb4_col CHAR(1) CHARACTER SET utf8mb4);
INSERT INTO tmp VALUES (0x000100cc,NULL);
UPDATE tmp SET utf8mb4_col = utf32_col;
SELECT HEX(utf32_col),HEX(utf8mb4_col) FROM tmp;
```

MySQL is very forgiving about additions of unassigned Unicode characters or private-use-area characters. There is in fact only one validity check for `utf32`: No code value may be greater than `0x10ffff`. For example, this is illegal:

```
INSERT INTO t (utf32_column) VALUES (0x110000); /* illegal */
```

10.9.8 Converting Between 3-Byte and 4-Byte Unicode Character Sets

This section describes issues that you may face when converting character data between the `utf8mb3` and `utf8mb4` character sets.

Note

This discussion focuses primarily on converting between `utf8mb3` and `utf8mb4`, but similar principles apply to converting between the `ucs2` character set and character sets such as `utf16` or `utf32`.

The `utf8mb3` and `utf8mb4` character sets differ as follows:

- `utf8mb3` supports only characters in the Basic Multilingual Plane (BMP). `utf8mb4` additionally supports supplementary characters that lie outside the BMP.
- `utf8mb3` uses a maximum of three bytes per character. `utf8mb4` uses a maximum of four bytes per character.

Note

This discussion refers to the `utf8mb3` and `utf8mb4` character set names to be explicit about referring to 3-byte and 4-byte UTF-8 character set data. The exception is that in table definitions, `utf8` is used because MySQL converts instances of `utf8mb3` specified in such definitions to `utf8`, which is an alias for `utf8mb3`.

One advantage of converting from `utf8mb3` to `utf8mb4` is that this enables applications to use supplementary characters. One tradeoff is that this may increase data storage space requirements.

In terms of table content, conversion from `utf8mb3` to `utf8mb4` presents no problems:

- For a BMP character, `utf8mb4` and `utf8mb3` have identical storage characteristics: same code values, same encoding, same length.
- For a supplementary character, `utf8mb4` requires four bytes to store it, whereas `utf8mb3` cannot store the character at all. When converting `utf8mb3` columns to `utf8mb4`, you need not worry about converting supplementary characters because there will be none.

In terms of table structure, these are the primary potential incompatibilities:

- For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum permitted length in characters is less for `utf8mb4` columns than for `utf8mb3` columns.
- For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters that can be indexed is less for `utf8mb4` columns than for `utf8mb3` columns.

Consequently, to convert tables from `utf8mb3` to `utf8mb4`, it may be necessary to change some column or index definitions.

Tables can be converted from `utf8mb3` to `utf8mb4` by using `ALTER TABLE`. Suppose that a table has this definition:

```
CREATE TABLE t1 (
  col1 CHAR(10) CHARACTER SET utf8 COLLATE utf8_unicode_ci NOT NULL,
  col2 CHAR(10) CHARACTER SET utf8 COLLATE utf8_bin NOT NULL
) CHARACTER SET utf8;
```

The following statement converts `t1` to use `utf8mb4`:

```
ALTER TABLE t1
  DEFAULT CHARACTER SET utf8mb4,
  MODIFY col1 CHAR(10)
    CHARACTER SET utf8mb4 COLLATE utf8mb4_unicode_ci NOT NULL,
  MODIFY col2 CHAR(10)
    CHARACTER SET utf8mb4 COLLATE utf8mb4_bin NOT NULL;
```

The catch when converting from `utf8mb3` to `utf8mb4` is that the maximum length of a column or index key is unchanged in terms of *bytes*. Therefore, it is smaller in terms of *characters* because the maximum length of a character is four bytes instead of three. For the `CHAR`, `VARCHAR`, and `TEXT` data types, watch for these issues when converting your MySQL tables:

- Check all definitions of `utf8mb3` columns and make sure they will not exceed the maximum length for the storage engine.
- Check all indexes on `utf8mb3` columns and make sure they will not exceed the maximum length for the storage engine. Sometimes the maximum can change due to storage engine enhancements.

If the preceding conditions apply, you must either reduce the defined length of columns or indexes, or continue to use `utf8mb3` rather than `utf8mb4`.

Here are some examples where structural changes may be needed:

- A `TINYTEXT` column can hold up to 255 bytes, so it can hold up to 85 3-byte or 63 4-byte characters. Suppose that you have a `TINYTEXT` column that uses `utf8mb3` but must be able to contain more than 63 characters. You cannot convert it to `utf8mb4` unless you also change the data type to a longer type such as `TEXT`.

Similarly, a very long `VARCHAR` column may need to be changed to one of the longer `TEXT` types if you want to convert it from `utf8mb3` to `utf8mb4`.

- `InnoDB` has a maximum index length of 767 bytes for tables that use `COMPACT` or `REDUNDANT` row format, so for `utf8mb3` or `utf8mb4` columns, you can index a maximum of 255 or 191 characters, respectively. If you currently have `utf8mb3` columns with indexes longer than 191 characters, you must index a smaller number of characters.

In an `InnoDB` table that uses `COMPACT` or `REDUNDANT` row format, these column and index definitions are legal:

```
col1 VARCHAR(500) CHARACTER SET utf8, INDEX (col1(255))
```

To use `utf8mb4` instead, the index must be smaller:

```
col1 VARCHAR(500) CHARACTER SET utf8mb4, INDEX (col1(191))
```

Note

For `InnoDB` tables that use `COMPRESSED` or `DYNAMIC` row format, [index key prefixes](#) longer than 767 bytes (up to 3072 bytes) are permitted. Tables created with these row formats enable you to index a maximum of 1024 or 768 characters for `utf8mb3` or `utf8mb4` columns, respectively. For related information, see [Section 15.22, “InnoDB Limits”](#), and [DYNAMIC Row Format](#).

The preceding types of changes are most likely to be required only if you have very long columns or indexes. Otherwise, you should be able to convert your tables from `utf8mb3` to `utf8mb4` without problems, using `ALTER TABLE` as described previously.

The following items summarize other potential incompatibilities:

- `SET NAMES 'utf8mb4'` causes use of the 4-byte character set for connection character sets. As long as no 4-byte characters are sent from the server, there should be no problems. Otherwise, applications that expect to receive a maximum of three bytes per character may have problems. Conversely, applications that expect to send 4-byte characters must ensure that the server understands them.
- For replication, if character sets that support supplementary characters are to be used on the source, all replicas must understand them as well.

Also, keep in mind the general principle that if a table has different definitions on the source and replica, this can lead to unexpected results. For example, the differences in maximum index key length make it risky to use `utf8mb3` on the source and `utf8mb4` on the replica.

If you have converted to `utf8mb4`, `utf16`, `utf16le`, or `utf32`, and then decide to convert back to `utf8mb3` or `ucs2` (for example, to downgrade to an older version of MySQL), these considerations apply:

- `utf8mb3` and `ucs2` data should present no problems.
- The server must be recent enough to recognize definitions referring to the character set from which you are converting.
- For object definitions that refer to the `utf8mb4` character set, you can dump them with `mysqldump` prior to downgrading, edit the dump file to change instances of `utf8mb4` to `utf8`, and reload the file in the older server, as long as there are no 4-byte characters in the data. The older server will see `utf8` in the dump file object definitions and create new objects that use the (3-byte) `utf8` character set.

10.10 Supported Character Sets and Collations

This section indicates which character sets MySQL supports. There is one subsection for each group of related character sets. For each character set, the permissible collations are listed.

To list the available character sets and their default collations, use the `SHOW CHARACTER SET` statement or query the `INFORMATION_SCHEMA.CHARACTER_SETS` table. For example:

```
mysql> SHOW CHARACTER SET;
```

Charset	Description	Default collation	Maxlen
armscii8	ARMSCII-8 Armenian	armscii8_general_ci	1
ascii	US ASCII	ascii_general_ci	1
big5	Big5 Traditional Chinese	big5_chinese_ci	2
binary	Binary pseudo charset	binary	1
cp1250	Windows Central European	cp1250_general_ci	1
cp1251	Windows Cyrillic	cp1251_general_ci	1
cp1256	Windows Arabic	cp1256_general_ci	1
cp1257	Windows Baltic	cp1257_general_ci	1
cp850	DOS West European	cp850_general_ci	1
cp852	DOS Central European	cp852_general_ci	1
cp866	DOS Russian	cp866_general_ci	1
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3
euckr	EUC-KR Korean	euckr_korean_ci	2
gb18030	China National Standard GB18030	gb18030_chinese_ci	4
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
geostd8	GEOSTD8 Georgian	geostd8_general_ci	1
greek	ISO 8859-7 Greek	greek_general_ci	1
hebrew	ISO 8859-8 Hebrew	hebrew_general_ci	1
hp8	HP West European	hp8_english_ci	1
keybcs2	DOS Kamenicky Czech-Slovak	keybcs2_general_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1

koi8u	KOI8-U Ukrainian	koi8u_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
latin5	ISO 8859-9 Turkish	latin5_turkish_ci	1
latin7	ISO 8859-13 Baltic	latin7_general_ci	1
macce	Mac Central European	macce_general_ci	1
macroman	Mac West European	macroman_general_ci	1
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
swe7	7bit Swedish	swe7_swedish_ci	1
tis620	TIS620 Thai	tis620_thai_ci	1
ucs2	UCS-2 Unicode	ucs2_general_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
utf16	UTF-16 Unicode	utf16_general_ci	4
utf16le	UTF-16LE Unicode	utf16le_general_ci	4
utf32	UTF-32 Unicode	utf32_general_ci	4
utf8	UTF-8 Unicode	utf8_general_ci	3
utf8mb4	UTF-8 Unicode	utf8mb4_0900_ai_ci	4

In cases where a character set has multiple collations, it might not be clear which collation is most suitable for a given application. To avoid choosing the wrong collation, it can be helpful to perform some comparisons with representative data values to make sure that a given collation sorts values the way you expect.

10.10.1 Unicode Character Sets

This section describes the collations available for Unicode character sets and their differentiating properties. For general information about Unicode, see [Section 10.9, “Unicode Support”](#).

MySQL supports multiple Unicode character sets:

- [utf8mb4](#): A UTF-8 encoding of the Unicode character set using one to four bytes per character.
- [utf8mb3](#): A UTF-8 encoding of the Unicode character set using one to three bytes per character.
- [utf8](#): An alias for [utf8mb3](#).
- [ucs2](#): The UCS-2 encoding of the Unicode character set using two bytes per character.
- [utf16](#): The UTF-16 encoding for the Unicode character set using two or four bytes per character. Like [ucs2](#) but with an extension for supplementary characters.
- [utf16le](#): The UTF-16LE encoding for the Unicode character set. Like [utf16](#) but little-endian rather than big-endian.
- [utf32](#): The UTF-32 encoding for the Unicode character set using four bytes per character.

Note

The [utf8mb3](#) character set is deprecated and will be removed in a future MySQL release. Please use [utf8mb4](#) instead. Although [utf8](#) is currently an alias for [utf8mb3](#), at some point [utf8](#) will become a reference to [utf8mb4](#). To avoid ambiguity about the meaning of [utf8](#), consider specifying [utf8mb4](#) explicitly for character set references instead of [utf8](#).

[utf8mb4](#), [utf16](#), [utf16le](#), and [utf32](#) support Basic Multilingual Plane (BMP) characters and supplementary characters that lie outside the BMP. [utf8](#) and [ucs2](#) support only BMP characters.

Most Unicode character sets have a general collation (indicated by [_general](#) in the name or by the absence of a language specifier), a binary collation (indicated by [_bin](#) in the name), and several language-specific collations (indicated by language specifiers). For example, for [utf8mb4](#), [utf8mb4_general_ci](#) and [utf8mb4_bin](#) are its general and binary collations, and [utf8mb4_danish_ci](#) is one of its language-specific collations.

Most character sets have a single binary collation. [utf8mb4](#) is an exception that has two: [utf8mb4_bin](#) and (as of MySQL 8.0.17) [utf8mb4_0900_bin](#). These two binary collations have the

same sort order but are distinguished by their pad attribute and collating weight characteristics. See [Collation Pad Attributes](#), and [Character Collating Weights](#).

Collation support for `utf16le` is limited. The only collations available are `utf16le_general_ci` and `utf16le_bin`. These are similar to `utf16_general_ci` and `utf16_bin`.

- [Unicode Collation Algorithm \(UCA\) Versions](#)
- [Collation Pad Attributes](#)
- [Language-Specific Collations](#)
- [_general_ci Versus _unicode_ci Collations](#)
- [Character Collating Weights](#)
- [Miscellaneous Information](#)

Unicode Collation Algorithm (UCA) Versions

MySQL implements the `xxx_unicode_ci` collations according to the Unicode Collation Algorithm (UCA) described at <http://www.unicode.org/reports/tr10/>. The collation uses the version-4.0.0 UCA weight keys: <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>. The `xxx_unicode_ci` collations have only partial support for the Unicode Collation Algorithm. Some characters are not supported, and combining marks are not fully supported. This affects primarily Vietnamese, Yoruba, and some smaller languages such as Navajo. A combined character is considered different from the same character written with a single unicode character in string comparisons, and the two characters are considered to have a different length (for example, as returned by the `CHAR_LENGTH()` function or in result set metadata).

Unicode collations based on UCA versions higher than 4.0.0 include the version in the collation name. Examples:

- `utf8mb4_unicode_520_ci` is based on UCA 5.2.0 weight keys (<http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>),
- `utf8mb4_0900_ai_ci` is based on UCA 9.0.0 weight keys (<http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt>).

The `LOWER()` and `UPPER()` functions perform case folding according to the collation of their argument. A character that has uppercase and lowercase versions only in a Unicode version higher than 4.0.0 is converted by these functions only if the argument collation uses a high enough UCA version.

Collation Pad Attributes

Collations based on UCA 9.0.0 and higher are faster than collations based on UCA versions prior to 9.0.0. They also have a pad attribute of `NO PAD`, in contrast to `PAD SPACE` as used in collations based on UCA versions prior to 9.0.0. For comparison of nonbinary strings, `NO PAD` collations treat spaces at the end of strings like any other character (see [Trailing Space Handling in Comparisons](#)).

To determine the pad attribute for a collation, use the `INFORMATION_SCHEMA.COLLATIONS` table, which has a `PAD_ATTRIBUTE` column. For example:

```
mysql> SELECT COLLATION_NAME, PAD_ATTRIBUTE
FROM INFORMATION_SCHEMA.COLLATIONS
WHERE CHARACTER_SET_NAME = 'utf8mb4';
```

COLLATION_NAME	PAD_ATTRIBUTE
utf8mb4_general_ci	PAD SPACE
utf8mb4_bin	PAD SPACE
utf8mb4_unicode_ci	PAD SPACE
utf8mb4_icelandic_ci	PAD SPACE
...	
utf8mb4_0900_ai_ci	NO PAD

utf8mb4_de_pb_0900_ai_ci	NO PAD	
utf8mb4_is_0900_ai_ci	NO PAD	
...		
utf8mb4_ja_0900_as_cs	NO PAD	
utf8mb4_ja_0900_as_cs_ks	NO PAD	
utf8mb4_0900_as_ci	NO PAD	
utf8mb4_ru_0900_ai_ci	NO PAD	
utf8mb4_ru_0900_as_cs	NO PAD	
utf8mb4_zh_0900_as_cs	NO PAD	
utf8mb4_0900_bin	NO PAD	
+-----+	+-----+	+-----+

Comparison of nonbinary string values (`CHAR`, `VARCHAR`, and `TEXT`) that have a `NO PAD` collation differ from other collations with respect to trailing spaces. For example, `'a'` and `'a '` compare as different strings, not the same string. This can be seen using the binary collations for `utf8mb4`. The `pad` attribute for `utf8mb4_bin` is `PAD SPACE`, whereas for `utf8mb4_0900_bin` it is `NO PAD`. Consequently, operations involving `utf8mb4_0900_bin` do not add trailing spaces, and comparisons involving strings with trailing spaces may differ for the two collations:

```
mysql> CREATE TABLE t1 (c CHAR(10) COLLATE utf8mb4_bin);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t1 VALUES('a');
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t1 WHERE c = 'a ';
+-----+
| c      |
+-----+
| a      |
+-----+
1 row in set (0.00 sec)

mysql> ALTER TABLE t1 MODIFY c CHAR(10) COLLATE utf8mb4_0900_bin;
Query OK, 0 rows affected (0.02 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1 WHERE c = 'a ';
Empty set (0.00 sec)
```

Language-Specific Collations

MySQL implements language-specific Unicode collations if the ordering based only on the Unicode Collation Algorithm (UCA) does not work well for a language. Language-specific collations are UCA-based, with additional language tailoring rules. Examples of such rules appear later in this section. For questions about particular language orderings, [unicode.org](http://www.unicode.org/cldr/charts/30/collation/index.html) provides Common Locale Data Repository (CLDR) collation charts at <http://www.unicode.org/cldr/charts/30/collation/index.html>.

For example, the nonlanguage-specific `utf8mb4_0900_ai_ci` and language-specific `utf8mb4_LOCALE_0900_ai_ci` Unicode collations each have these characteristics:

- The collation is based on UCA 9.0.0 and CLDR v30, is accent-insensitive and case-insensitive. These characteristics are indicated by `_0900`, `_ai`, and `_ci` in the collation name. Exception: `utf8mb4_la_0900_ai_ci` is not based on CLDR because Classical Latin is not defined in CLDR.
- The collation works for all characters in the range [U+0, U+10FFFF].
- If the collation is not language specific, it sorts all characters, including supplementary characters, in default order (described following). If the collation is language specific, it sorts characters of the language correctly according to language-specific rules, and characters not in the language in default order.
- By default, the collation sorts characters having a code point listed in the DUCET table (Default Unicode Collation Element Table) according to the weight value assigned in the table. The collation sorts characters not having a code point listed in the DUCET table using their implicit weight value, which is constructed according to the UCA.

- For non-language-specific collations, characters in contraction sequences are treated as separate characters. For language-specific collations, contractions might change character sorting order.

A collation name that includes a locale code or language name shown in the following table is a language-specific collation. Unicode character sets may include collations for one or more of these languages.

Table 10.3 Unicode Collation Language Specifiers

Language	Language Specifier
Chinese	zh
Classical Latin	la or roman
Croatian	hr or croatian
Czech	cs or czech
Danish	da or danish
Esperanto	eo or esperanto
Estonian	et or estonian
German phone book order	de_pb or german2
Hungarian	hu or hungarian
Icelandic	is or icelandic
Japanese	ja
Latvian	lv or latvian
Lithuanian	lt or lithuanian
Persian	persian
Polish	pl or polish
Romanian	ro or romanian
Russian	ru
Sinhala	sinhala
Slovak	sk or slovak
Slovenian	sl or slovenian
Modern Spanish	es or spanish
Traditional Spanish	es_trad or spanish2
Swedish	sv or swedish
Turkish	tr or turkish
Vietnamese	vi or vietnamese

Croatian collations are tailored for these Croatian letters: Č, Ć, Dž, Đ, Lj, Nj, Š, Ž.

Danish collations may also be used for Norwegian.

For Japanese, the `utf8mb4` character set includes `utf8mb4_ja_0900_as_cs` and `utf8mb4_ja_0900_as_cs_ks` collations. Both collations are accent-sensitive and case-sensitive. `utf8mb4_ja_0900_as_cs_ks` is also kana-sensitive and distinguishes Katakana characters from Hiragana characters, whereas `utf8mb4_ja_0900_as_cs` treats Katakana and Hiragana characters as equal for sorting. Applications that require a Japanese collation but not kana sensitivity may use `utf8mb4_ja_0900_as_cs` for better sort performance. `utf8mb4_ja_0900_as_cs` uses three weight levels for sorting; `utf8mb4_ja_0900_as_cs_ks` uses four.

For Classical Latin collations that are accent-insensitive, `I` and `J` compare as equal, and `U` and `V` compare as equal. `I` and `J`, and `U` and `V` compare as equal on the base letter level. In other words, `J` is regarded as an accented `I`, and `U` is regarded as an accented `V`.

Spanish collations are available for modern and traditional Spanish. For both, ñ (n-tilde) is a separate letter between n and o. In addition, for traditional Spanish, ch is a separate letter between c and d, and ll is a separate letter between l and m.

Traditional Spanish collations may also be used for Asturian and Galician.

Swedish collations include Swedish rules. For example, in Swedish, the following relationship holds, which is not something expected by a German or French speaker:

```
Ü = Y < Ö
```

_general_ci Versus _unicode_ci Collations

For any Unicode character set, operations performed using the `xxx_general_ci` collation are faster than those for the `xxx_unicode_ci` collation. For example, comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. The reason is that `utf8_unicode_ci` supports mappings such as expansions; that is, when one character compares as equal to combinations of other characters. For example, ß is equal to ss in German and some other languages. `utf8_unicode_ci` also supports contractions and ignorable characters. `utf8_general_ci` is a legacy collation that does not support expansions, contractions, or ignorable characters. It can make only one-to-one comparisons between characters.

To further illustrate, the following equalities hold in both `utf8_general_ci` and `utf8_unicode_ci` (for the effect of this in comparisons or searches, see [Section 10.8.6, “Examples of the Effect of Collation”](#)):

```
Ä = A
Ö = O
Ü = U
```

A difference between the collations is that this is true for `utf8_general_ci`:

```
ß = s
```

Whereas this is true for `utf8_unicode_ci`, which supports the German DIN-1 ordering (also known as dictionary order):

```
ß = ss
```

MySQL implements `utf8` language-specific collations if the ordering with `utf8_unicode_ci` does not work well for a language. For example, `utf8_unicode_ci` works fine for German dictionary order and French, so there is no need to create special `utf8` collations.

`utf8_general_ci` also is satisfactory for both German and French, except that ß is equal to s, and not to ss. If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8_unicode_ci` because it is more accurate.

If you require German DIN-2 (phone book) ordering, use the `utf8_german2_ci` collation, which compares the following sets of characters equal:

```
Ä = Æ = AE
Ö = Œ = OE
Ü = UE
ß = ss
```

`utf8_german2_ci` is similar to `latin1_german2_ci`, but the latter does not compare Æ equal to AE or Œ equal to OE. There is no `utf8_german_ci` corresponding to `latin1_german_ci` for German dictionary order because `utf8_general_ci` suffices.

Character Collating Weights

A character's collating weight is determined as follows:

- For all Unicode collations except the `_bin` (binary) collations, MySQL performs a table lookup to find a character's collating weight.
- For `_bin` collations except `utf8mb4_0900_bin`, the weight is based on the code point, possibly with leading zero bytes added.
- For `utf8mb4_0900_bin`, the weight is the `utf8mb4` encoding bytes. The sort order is the same as for `utf8mb4_bin`, but much faster.

Collating weights can be displayed using the `WEIGHT_STRING()` function. (See [Section 12.8, “String Functions and Operators”](#).) If a collation uses a weight lookup table, but a character is not in the table (for example, because it is a “new” character), collating weight determination becomes more complex:

- For BMP characters in general collations (`xxx_general_ci`), the weight is the code point.
- For BMP characters in UCA collations (for example, `xxx_unicode_ci` and language-specific collations), the following algorithm applies:

```
if (code >= 0x3400 && code <= 0x4DB5)
    base= 0xFB80; /* CJK Ideograph Extension */
else if (code >= 0x4E00 && code <= 0x9FA5)
    base= 0xFB40; /* CJK Ideograph */
else
    base= 0xFBC0; /* All other characters */
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
```

The result is a sequence of two collating elements, `aaaa` followed by `bbbb`. For example:

```
mysql> SELECT HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci));
+-----+
| HEX(WEIGHT_STRING(_ucs2 0x04CF COLLATE ucs2_unicode_ci)) |
+-----+
| FBC084CF                                                    |
+-----+
```

Thus, `U+04cf CYRILLIC SMALL LETTER PALOCHKA` is, with all UCA 4.0.0 collations, greater than `U+04c0 CYRILLIC LETTER PALOCHKA`. With UCA 5.2.0 collations, all palochkas sort together.

- For supplementary characters in general collations, the weight is the weight for `0xffff REPLACEMENT CHARACTER`. For supplementary characters in UCA 4.0.0 collations, their collating weight is `0xffff`. That is, to MySQL, all supplementary characters are equal to each other, and greater than almost all BMP characters.

An example with Deseret characters and `COUNT(DISTINCT)`:

```
CREATE TABLE t (s1 VARCHAR(5) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0xffff); /* REPLACEMENT CHARACTER */
INSERT INTO t VALUES (0x010412); /* DESERET CAPITAL LETTER BEE */
INSERT INTO t VALUES (0x010413); /* DESERET CAPITAL LETTER TEE */
SELECT COUNT(DISTINCT s1) FROM t;
```

The result is 2 because in the MySQL `xxx_unicode_ci` collations, the replacement character has a weight of `0x0dc6`, whereas Deseret Bee and Deseret Tee both have a weight of `0xffff`. (Were the `utf32_general_ci` collation used instead, the result is 1 because all three characters have a weight of `0xffff` in that collation.)

An example with cuneiform characters and `WEIGHT_STRING()`:

```
/*
The four characters in the INSERT string are
00000041 # LATIN CAPITAL LETTER A
0001218F # CUNEIFORM SIGN KAB
000121A7 # CUNEIFORM SIGN KISH
00000042 # LATIN CAPITAL LETTER B
```

```
*/
CREATE TABLE t (s1 CHAR(4) CHARACTER SET utf32 COLLATE utf32_unicode_ci);
INSERT INTO t VALUES (0x000000410001218f000121a700000042);
SELECT HEX(WEIGHT_STRING(s1)) FROM t;
```

The result is:

```
0E33 FFFD FFFD 0E4A
```

[0E33](#) and [0E4A](#) are primary weights as in [UCA 4.0.0](#). [FFFD](#) is the weight for KAB and also for KISH.

The rule that all supplementary characters are equal to each other is nonoptimal but is not expected to cause trouble. These characters are very rare, so it is very rare that a multi-character string consists entirely of supplementary characters. In Japan, since the supplementary characters are obscure Kanji ideographs, the typical user does not care what order they are in, anyway. If you really want rows sorted by the MySQL rule and secondarily by code point value, it is easy:

```
ORDER BY s1 COLLATE utf32_unicode_ci, s1 COLLATE utf32_bin
```

- For supplementary characters based on UCA versions higher than 4.0.0 (for example, [xxx_unicode_520_ci](#)), supplementary characters do not necessarily all have the same collating weight. Some have explicit weights from the UCA [allkeys.txt](#) file. Others have weights calculated from this algorithm:

```
aaaa= base + (code >> 15);
bbbb= (code & 0x7FFF) | 0x8000;
```

There is a difference between “ordering by the character's code value” and “ordering by the character's binary representation,” a difference that appears only with [utf16_bin](#), because of surrogates.

Suppose that [utf16_bin](#) (the binary collation for [utf16](#)) was a binary comparison “byte by byte” rather than “character by character.” If that were so, the order of characters in [utf16_bin](#) would differ from the order in [utf8_bin](#). For example, the following chart shows two rare characters. The first character is in the range [E000-FFFF](#), so it is greater than a surrogate but less than a supplementary. The second character is a supplementary.

Code point	Character	utf8	utf16
-----	-----	----	-----
0FF9D	HALFWIDTH KATAKANA LETTER N	EF BE 9D	FF 9D
10384	UGARITIC LETTER DELTA	F0 90 8E 84	D8 00 DF 84

The two characters in the chart are in order by code point value because [0xff9d](#) < [0x10384](#). And they are in order by [utf8](#) value because [0xef](#) < [0xf0](#). But they are not in order by [utf16](#) value, if we use byte-by-byte comparison, because [0xff](#) > [0xd8](#).

So MySQL's [utf16_bin](#) collation is not “byte by byte.” It is “by code point.” When MySQL sees a supplementary-character encoding in [utf16](#), it converts to the character's code-point value, and then compares. Therefore, [utf8_bin](#) and [utf16_bin](#) are the same ordering. This is consistent with the SQL:2008 standard requirement for a UCS_BASIC collation: “UCS_BASIC is a collation in which the ordering is determined entirely by the Unicode scalar values of the characters in the strings being sorted. It is applicable to the UCS character repertoire. Since every character repertoire is a subset of the UCS repertoire, the UCS_BASIC collation is potentially applicable to every character set. NOTE 11: The Unicode scalar value of a character is its code point treated as an unsigned integer.”

If the character set is [ucs2](#), comparison is byte-by-byte, but [ucs2](#) strings should not contain surrogates, anyway.

Miscellaneous Information

The [xxx_general_mysql500_ci](#) collations preserve the pre-5.1.24 ordering of the original [xxx_general_ci](#) collations and permit upgrades for tables created before MySQL 5.1.24 (Bug #27877).

10.10.2 West European Character Sets

Western European character sets cover most West European languages, such as French, Spanish, Catalan, Basque, Portuguese, Italian, Albanian, Dutch, German, Danish, Swedish, Norwegian, Finnish, Faroese, Icelandic, Irish, Scottish, and English.

- `ascii` (US ASCII) collations:
 - `ascii_bin`
 - `ascii_general_ci` (default)
- `cp850` (DOS West European) collations:
 - `cp850_bin`
 - `cp850_general_ci` (default)
- `dec8` (DEC Western European) collations:
 - `dec8_bin`
 - `dec8_swedish_ci` (default)
- `hp8` (HP Western European) collations:
 - `hp8_bin`
 - `hp8_english_ci` (default)
- `latin1` (cp1252 West European) collations:
 - `latin1_bin`
 - `latin1_danish_ci`
 - `latin1_general_ci`
 - `latin1_general_cs`
 - `latin1_german1_ci`
 - `latin1_german2_ci`
 - `latin1_spanish_ci`
 - `latin1_swedish_ci` (default)

MySQL's `latin1` is the same as the Windows `cp1252` character set. This means it is the same as the official [ISO 8859-1](#) or IANA (Internet Assigned Numbers Authority) `latin1`, except that IANA `latin1` treats the code points between `0x80` and `0x9f` as “undefined,” whereas `cp1252`, and therefore MySQL's `latin1`, assign characters for those positions. For example, `0x80` is the Euro sign. For the “undefined” entries in `cp1252`, MySQL translates `0x81` to Unicode `0x0081`, `0x8d` to `0x008d`, `0x8f` to `0x008f`, `0x90` to `0x0090`, and `0x9d` to `0x009d`.

The `latin1_swedish_ci` collation is the default that probably is used by the majority of MySQL customers. Although it is frequently said that it is based on the Swedish/Finnish collation rules, there are Swedes and Finns who disagree with this statement.

The `latin1_german1_ci` and `latin1_german2_ci` collations are based on the DIN-1 and DIN-2 standards, where DIN stands for *Deutsches Institut für Normung* (the German equivalent of ANSI). DIN-1 is called the “dictionary collation” and DIN-2 is called the “phone book collation.”

For an example of the effect this has in comparisons or when doing searches, see [Section 10.8.6, “Examples of the Effect of Collation”](#).

- `latin1_german1_ci` (dictionary) rules:

```
Ä = A
Ö = O
Ü = U
ß = s
```

- `latin1_german2_ci` (phone-book) rules:

```
Ä = AE
Ö = OE
Ü = UE
ß = ss
```

In the `latin1_spanish_ci` collation, ñ (n-tilde) is a separate letter between `n` and `o`.

- `macroman` (Mac West European) collations:
 - `macroman_bin`
 - `macroman_general_ci` (default)
- `swe7` (7bit Swedish) collations:
 - `swe7_bin`
 - `swe7_swedish_ci` (default)

10.10.3 Central European Character Sets

MySQL provides some support for character sets used in the Czech Republic, Slovakia, Hungary, Romania, Slovenia, Croatia, Poland, and Serbia (Latin).

- `cp1250` (Windows Central European) collations:
 - `cp1250_bin`
 - `cp1250_croatian_ci`
 - `cp1250_czech_cs`
 - `cp1250_general_ci` (default)
 - `cp1250_polish_ci`
- `cp852` (DOS Central European) collations:
 - `cp852_bin`
 - `cp852_general_ci` (default)
- `keybcs2` (DOS Kamenicky Czech-Slovak) collations:
 - `keybcs2_bin`
 - `keybcs2_general_ci` (default)
- `latin2` (ISO 8859-2 Central European) collations:
 - `latin2_bin`
 - `latin2_croatian_ci`

- `latin2_czech_cs`
- `latin2_general_ci` (default)
- `latin2_hungarian_ci`
- `macce` (Mac Central European) collations:
 - `macce_bin`
 - `macce_general_ci` (default)

10.10.4 South European and Middle East Character Sets

South European and Middle Eastern character sets supported by MySQL include Armenian, Arabic, Georgian, Greek, Hebrew, and Turkish.

- `armscii8` (ARMSCII-8 Armenian) collations:
 - `armscii8_bin`
 - `armscii8_general_ci` (default)
- `cp1256` (Windows Arabic) collations:
 - `cp1256_bin`
 - `cp1256_general_ci` (default)
- `geostd8` (GEOSTD8 Georgian) collations:
 - `geostd8_bin`
 - `geostd8_general_ci` (default)
- `greek` (ISO 8859-7 Greek) collations:
 - `greek_bin`
 - `greek_general_ci` (default)
- `hebrew` (ISO 8859-8 Hebrew) collations:
 - `hebrew_bin`
 - `hebrew_general_ci` (default)
- `latin5` (ISO 8859-9 Turkish) collations:
 - `latin5_bin`
 - `latin5_turkish_ci` (default)

10.10.5 Baltic Character Sets

The Baltic character sets cover Estonian, Latvian, and Lithuanian languages.

- `cp1257` (Windows Baltic) collations:
 - `cp1257_bin`
 - `cp1257_general_ci` (default)

- `cp1257_lithuanian_ci`
- `latin7` (ISO 8859-13 Baltic) collations:
 - `latin7_bin`
 - `latin7_estonian_cs`
 - `latin7_general_ci` (default)
 - `latin7_general_cs`

10.10.6 Cyrillic Character Sets

The Cyrillic character sets and collations are for use with Belarusian, Bulgarian, Russian, Ukrainian, and Serbian (Cyrillic) languages.

- `cp1251` (Windows Cyrillic) collations:
 - `cp1251_bin`
 - `cp1251_bulgarian_ci`
 - `cp1251_general_ci` (default)
 - `cp1251_general_cs`
 - `cp1251_ukrainian_ci`
- `cp866` (DOS Russian) collations:
 - `cp866_bin`
 - `cp866_general_ci` (default)
- `koi8r` (KOI8-R Relcom Russian) collations:
 - `koi8r_bin`
 - `koi8r_general_ci` (default)
- `koi8u` (KOI8-U Ukrainian) collations:
 - `koi8u_bin`
 - `koi8u_general_ci` (default)

10.10.7 Asian Character Sets

The Asian character sets that we support include Chinese, Japanese, Korean, and Thai. These can be complicated. For example, the Chinese sets must allow for thousands of different characters. See [Section 10.10.7.1, “The cp932 Character Set”](#), for additional information about the `cp932` and `sjis` character sets. See [Section 10.10.7.2, “The gb18030 Character Set”](#), for additional information about character set support for the Chinese National Standard GB 18030.

For answers to some common questions and problems relating support for Asian character sets in MySQL, see [Section A.11, “MySQL 8.0 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”](#).

- `big5` (Big5 Traditional Chinese) collations:
 - `big5_bin`

- `big5_chinese_ci` (default)
- `cp932` (SJIS for Windows Japanese) collations:
 - `cp932_bin`
 - `cp932_japanese_ci` (default)
- `eucjpms` (UJIS for Windows Japanese) collations:
 - `eucjpms_bin`
 - `eucjpms_japanese_ci` (default)
- `euckr` (EUC-KR Korean) collations:
 - `euckr_bin`
 - `euckr_korean_ci` (default)
- `gb2312` (GB2312 Simplified Chinese) collations:
 - `gb2312_bin`
 - `gb2312_chinese_ci` (default)
- `gbk` (GBK Simplified Chinese) collations:
 - `gbk_bin`
 - `gbk_chinese_ci` (default)
- `gb18030` (China National Standard GB18030) collations:
 - `gb18030_bin`
 - `gb18030_chinese_ci` (default)
 - `gb18030_unicode_520_ci`
- `sjis` (Shift-JIS Japanese) collations:
 - `sjis_bin`
 - `sjis_japanese_ci` (default)
- `tis620` (TIS620 Thai) collations:
 - `tis620_bin`
 - `tis620_thai_ci` (default)
- `ujis` (EUC-JP Japanese) collations:
 - `ujis_bin`
 - `ujis_japanese_ci` (default)

The `big5_chinese_ci` collation sorts on number of strokes.

10.10.7.1 The `cp932` Character Set

Why is `cp932` needed?

In MySQL, the `sjis` character set corresponds to the `Shift_JIS` character set defined by IANA, which supports JIS X0201 and JIS X0208 characters. (See <http://www.iana.org/assignments/character-sets>.)

However, the meaning of “SHIFT JIS” as a descriptive term has become very vague and it often includes the extensions to `Shift_JIS` that are defined by various vendors.

For example, “SHIFT JIS” used in Japanese Windows environments is a Microsoft extension of `Shift_JIS` and its exact name is `Microsoft Windows Codepage : 932` or `cp932`. In addition to the characters supported by `Shift_JIS`, `cp932` supports extension characters such as NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.

Many Japanese users have experienced problems using these extension characters. These problems stem from the following factors:

- MySQL automatically converts character sets.
- Character sets are converted using Unicode (`ucs2`).
- The `sjis` character set does not support the conversion of these extension characters.
- There are several conversion rules from so-called “SHIFT JIS” to Unicode, and some characters are converted to Unicode differently depending on the conversion rule. MySQL supports only one of these rules (described later).

The MySQL `cp932` character set is designed to solve these problems.

Because MySQL supports character set conversion, it is important to separate IANA `Shift_JIS` and `cp932` into two different character sets because they provide different conversion rules.

How does `cp932` differ from `sjis`?

The `cp932` character set differs from `sjis` in the following ways:

- `cp932` supports NEC special characters, NEC selected—IBM extended characters, and IBM selected characters.
- Some `cp932` characters have two different code points, both of which convert to the same Unicode code point. When converting from Unicode back to `cp932`, one of the code points must be selected. For this “round trip conversion,” the rule recommended by Microsoft is used. (See <http://support.microsoft.com/kb/170559/EN-US/>.)

The conversion rule works like this:

- If the character is in both JIS X 0208 and NEC special characters, use the code point of JIS X 0208.
- If the character is in both NEC special characters and IBM selected characters, use the code point of NEC special characters.
- If the character is in both IBM selected characters and NEC selected—IBM extended characters, use the code point of IBM extended characters.

The table shown at <https://msdn.microsoft.com/en-us/goglobal/cc305152.aspx> provides information about the Unicode values of `cp932` characters. For `cp932` table entries with characters under which a four-digit number appears, the number represents the corresponding Unicode (`ucs2`) encoding. For table entries with an underlined two-digit value appears, there is a range of `cp932` character values that begin with those two digits. Clicking such a table entry takes you to a page that displays the Unicode value for each of the `cp932` characters that begin with those digits.

The following links are of special interest. They correspond to the encodings for the following sets of characters:

- NEC special characters (lead byte 0x87):

<https://msdn.microsoft.com/en-us/goglobal/gg674964>

- NEC selected—IBM extended characters (lead byte 0xED and 0xEE):

<https://msdn.microsoft.com/en-us/goglobal/gg671837>
<https://msdn.microsoft.com/en-us/goglobal/gg671838>

- IBM selected characters (lead byte 0xFA, 0xFB, 0xFC):

<https://msdn.microsoft.com/en-us/goglobal/gg671839>
<https://msdn.microsoft.com/en-us/goglobal/gg671840>
<https://msdn.microsoft.com/en-us/goglobal/gg671841>

- cp932 supports conversion of user-defined characters in combination with eucjpm, and solves the problems with sjis/ujis conversion. For details, please refer to <http://www.sjfaq.org/faq/encodings.html>.

For some characters, conversion to and from ucs2 is different for sjis and cp932. The following tables illustrate these differences.

Conversion to ucs2:

sjis/cp932 Value	sjis -> ucs2 Conversion	cp932 -> ucs2 Conversion
5C	005C	005C
7E	007E	007E
815C	2015	2015
815F	005C	FF3C
8160	301C	FF5E
8161	2016	2225
817C	2212	FF0D
8191	00A2	FFE0
8192	00A3	FFE1
81CA	00AC	FFE2

Conversion from ucs2:

ucs2 value	ucs2 -> sjis Conversion	ucs2 -> cp932 Conversion
005C	815F	5C
007E	7E	7E
00A2	8191	3F
00A3	8192	3F
00AC	81CA	3F
2015	815C	815C
2016	8161	3F
2212	817C	3F
2225	3F	8161
301C	8160	3F
FF0D	3F	817C
FF3C	3F	815F

ucs2 value	ucs2 -> sjis Conversion	ucs2 -> cp932 Conversion
FF5E	3F	8160
FFE0	3F	8191
FFE1	3F	8192
FFE2	3F	81CA

Users of any Japanese character sets should be aware that using `--character-set-client-handshake` (or `--skip-character-set-client-handshake`) has an important effect. See [Section 5.1.7, “Server Command Options”](#).

10.10.7.2 The gb18030 Character Set

In MySQL, the `gb18030` character set corresponds to the “Chinese National Standard GB 18030-2005: Information technology—Chinese coded character set”, which is the official character set of the People's Republic of China (PRC).

Characteristics of the MySQL gb18030 Character Set

- Supports all code points defined by the GB 18030-2005 standard. Unassigned code points in the ranges (GB+8431A439, GB+90308130) and (GB+E3329A36, GB+EF39EF39) are treated as '?' (0x3F). Conversion of unassigned code points return '?'.
- Supports UPPER and LOWER conversion for all GB18030 code points. Case folding defined by Unicode is also supported (based on `CaseFolding-6.3.0.txt`).
- Supports Conversion of data to and from other character sets.
- Supports SQL statements such as `SET NAMES`.
- Supports comparison between `gb18030` strings, and between `gb18030` strings and strings of other character sets. There is a conversion if strings have different character sets. Comparisons that include or ignore trailing spaces are also supported.
- The private use area (U+E000, U+F8FF) in Unicode is mapped to `gb18030`.
- There is no mapping between (U+D800, U+DFFF) and GB18030. Attempted conversion of code points in this range returns '?'.
- If an incoming sequence is illegal, an error or warning is returned. If an illegal sequence is used in `CONVERT()`, an error is returned. Otherwise, a warning is returned.
- For consistency with `utf8` and `utf8mb4`, UPPER is not supported for ligatures.
- Searches for ligatures also match uppercase ligatures when using the `gb18030_unicode_520_ci` collation.
- If a character has more than one uppercase character, the chosen uppercase character is the one whose lowercase is the character itself.
- The minimum multibyte length is 1 and the maximum is 4. The character set determines the length of a sequence using the first 1 or 2 bytes.

Supported Collations

- `gb18030_bin`: A binary collation.
- `gb18030_chinese_ci`: The default collation, which supports Pinyin. Sorting of non-Chinese characters is based on the order of the original sort key. The original sort key is `GB(UPPER(ch))` if `UPPER(ch)` exists. Otherwise, the original sort key is `GB(ch)`. Chinese characters are sorted

according to the Pinyin collation defined in the Unicode Common Locale Data Repository (CLDR 24). Non-Chinese characters are sorted before Chinese characters with the exception of `GB+FE39FE39`, which is the code point maximum.

- `gb18030_unicode_520_ci`: A Unicode collation. Use this collation if you need to ensure that ligatures are sorted correctly.

10.10.8 The Binary Character Set

The `binary` character set is the character set for binary strings, which are sequences of bytes. The `binary` character set has one collation, also named `binary`. Comparison and sorting are based on numeric byte values, rather than on numeric character code values (which for multibyte characters differ from numeric byte values). For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 10.8.5, “The binary Collation Compared to `_bin` Collations”](#).

For the `binary` character set, the concepts of lettercase and accent equivalence do not apply:

- For single-byte characters stored as binary strings, character and byte boundaries are the same, so lettercase and accent differences are significant in comparisons. That is, the `binary` collation is case-sensitive and accent-sensitive.

```
mysql> SET NAMES 'binary';
mysql> SELECT CHARSET('abc'), COLLATION('abc');
+-----+-----+
| CHARSET('abc') | COLLATION('abc') |
+-----+-----+
| binary        | binary          |
+-----+-----+
mysql> SELECT 'abc' = 'ABC', 'a' = 'ä';
+-----+-----+
| 'abc' = 'ABC' | 'a' = 'ä'       |
+-----+-----+
| 0             | 0               |
+-----+-----+
```

- For multibyte characters stored as binary strings, character and byte boundaries differ. Character boundaries are lost, so comparisons that depend on them are not meaningful.

To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+
```

To convert a string expression to a binary string, these constructs are equivalent:

```
BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
```

If a value is a character string literal, the `_binary` introducer may be used to designate it as a binary string. For example:

```
_binary 'a'
```

The `_binary` introducer is permitted for hexadecimal literals and bit-value literals as well, but unnecessary; such literals are binary strings by default.

For more information about introducers, see [Section 10.3.8, “Character Set Introducers”](#).

10.11 Restrictions on Character Sets

- Identifiers are stored in `mysql` database tables (`user`, `db`, and so forth) using `utf8`, but identifiers can contain only characters in the Basic Multilingual Plane (BMP). Supplementary characters are not permitted in identifiers.
- The `ucs2`, `utf16`, `utf16le`, and `utf32` character sets have the following restrictions:
 - None of them can be used as the client character set. See [Impermissible Client Character Sets](#).
 - It is currently not possible to use `LOAD DATA` to load data files that use these character sets.
 - `FULLTEXT` indexes cannot be created on a column that uses any of these character sets. However, you can perform `IN BOOLEAN MODE` searches on the column without an index.
- The `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

10.12 Setting the Error Message Language

By default, `mysqld` produces error messages in English, but they can be displayed instead in any of several other languages: Czech, Danish, Dutch, Estonian, French, German, Greek, Hungarian, Italian, Japanese, Korean, Norwegian, Norwegian-ny, Polish, Portuguese, Romanian, Russian, Slovak, Spanish, or Swedish. This applies to messages the server writes to the error log and sends to clients.

To select the language in which the server writes error messages, follow the instructions in this section. For information about changing the character set for error messages (rather than the language), see [Section 10.6, “Error Message Character Set”](#). For general information about configuring error logging, see [Section 5.4.2, “The Error Log”](#).

The server searches for the error message file using these rules:

- It looks for the file in a directory constructed from two system variable values, `lc_messages_dir` and `lc_messages`, with the latter converted to a language name. Suppose that you start the server using this command:

```
mysqld --lc_messages_dir=/usr/share/mysql --lc_messages=fr_FR
```

In this case, `mysqld` maps the locale `fr_FR` to the language `french` and looks for the error file in the `/usr/share/mysql/french` directory.

By default, the language files are located in the `share/mysql/LANGUAGE` directory under the MySQL base directory.

- If the message file cannot be found in the directory constructed as just described, the server ignores the `lc_messages` value and uses only the `lc_messages_dir` value as the location in which to look.
- If the server cannot find the configured message file, it writes a message to the error log to indicate the problem and defaults to built-in English messages.

The `lc_messages_dir` system variable can be set only at server startup and has only a global read-only value at runtime. `lc_messages` can be set at server startup and has global and session values that can be modified at runtime. Thus, the error message language can be changed while the server is running, and each client can have its own error message language by setting its session `lc_messages` value to the desired locale name. For example, if the server is using the `fr_FR` locale for error messages, a client can execute this statement to receive error messages in English:

```
SET lc_messages = 'en_US';
```

10.13 Adding a Character Set

This section discusses the procedure for adding a character set to MySQL. The proper procedure depends on whether the character set is simple or complex:

- If the character set does not need special string collating routines for sorting and does not need multibyte character support, it is simple.
- If the character set needs either of those features, it is complex.

For example, `greek` and `swe7` are simple character sets, whereas `big5` and `czech` are complex character sets.

To use the following instructions, you must have a MySQL source distribution. In the instructions, `MYSET` represents the name of the character set that you want to add.

1. Add a `<charset>` element for `MYSET` to the `sql/share/charsets/Index.xml` file. Use the existing contents in the file as a guide to adding new contents. A partial listing for the `latin1` `<charset>` element follows:

```
<charset name="latin1">
  <family>Western</family>
  <description>cp1252 West European</description>
  ...
  <collation name="latin1_swedish_ci" id="8" order="Finnish, Swedish">
    <flag>primary</flag>
    <flag>compiled</flag>
  </collation>
  <collation name="latin1_danish_ci" id="15" order="Danish"/>
  ...
  <collation name="latin1_bin" id="47" order="Binary">
    <flag>binary</flag>
    <flag>compiled</flag>
  </collation>
  ...
</charset>
```

The `<charset>` element must list all the collations for the character set. These must include at least a binary collation and a default (primary) collation. The default collation is often named using a suffix of `general_ci` (general, case-insensitive). It is possible for the binary collation to be the default collation, but usually they are different. The default collation should have a `primary` flag. The binary collation should have a `binary` flag.

You must assign a unique ID number to each collation. The range of IDs from 1024 to 2047 is reserved for user-defined collations. To find the maximum of the currently used collation IDs, use this query:

```
SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
```

2. This step depends on whether you are adding a simple or complex character set. A simple character set requires only a configuration file, whereas a complex character set requires C source file that defines collation functions, multibyte functions, or both.

For a simple character set, create a configuration file, `MYSET.xml`, that describes the character set properties. Create this file in the `sql/share/charsets` directory. You can use a copy of `latin1.xml` as the basis for this file. The syntax for the file is very simple:

- Comments are written as ordinary XML comments (`<!-- text -->`).
- Words within `<map>` array elements are separated by arbitrary amounts of whitespace.
- Each word within `<map>` array elements must be a number in hexadecimal format.

- The `<map>` array element for the `<ctype>` element has 257 words. The other `<map>` array elements after that have 256 words. See [Section 10.13.1, “Character Definition Arrays”](#).
- For each collation listed in the `<charset>` element for the character set in `Index.xml`, `MYSET.xml` must contain a `<collation>` element that defines the character ordering.

For a complex character set, create a C source file that describes the character set properties and defines the support routines necessary to properly perform operations on the character set:

- Create the file `ctype-MYSET.c` in the `strings` directory. Look at one of the existing `ctype-*.c` files (such as `ctype-big5.c`) to see what needs to be defined. The arrays in your file must have names like `ctype_MYSET`, `to_lower_MYSET`, and so on. These correspond to the arrays for a simple character set. See [Section 10.13.1, “Character Definition Arrays”](#).
 - For each `<collation>` element listed in the `<charset>` element for the character set in `Index.xml`, the `ctype-MYSET.c` file must provide an implementation of the collation.
 - If the character set requires string collating functions, see [Section 10.13.2, “String Collating Support for Complex Character Sets”](#).
 - If the character set requires multibyte character support, see [Section 10.13.3, “Multi-Byte Character Support for Complex Character Sets”](#).
3. Modify the configuration information. Use the existing configuration information as a guide to adding information for `MYSYS`. The example here assumes that the character set has default and binary collations, but more lines are needed if `MYSET` has additional collations.

- a. Edit `mysys/charset-def.c`, and “register” the collations for the new character set.

Add these lines to the “declaration” section:

```
#ifndef HAVE_CHARSET_MYSET
extern CHARSET_INFO my_charset_MYSET_general_ci;
extern CHARSET_INFO my_charset_MYSET_bin;
#endif
```

Add these lines to the “registration” section:

```
#ifndef HAVE_CHARSET_MYSET
add_compiled_collation(&my_charset_MYSET_general_ci);
add_compiled_collation(&my_charset_MYSET_bin);
#endif
```

- b. If the character set uses `ctype-MYSET.c`, edit `strings/CMakeLists.txt` and add `ctype-MYSET.c` to the definition of the `STRINGS_SOURCES` variable.
- c. Edit `cmake/character_sets.cmake`:
 - i. Add `MYSET` to the value of with `CHARSETS_AVAILABLE` in alphabetic order.
 - ii. Add `MYSET` to the value of `CHARSETS_COMPLEX` in alphabetic order. This is needed even for simple character sets, or CMake will not recognize `-DDEFAULT_CHARSET=MYSET`.

4. Reconfigure, recompile, and test.

10.13.1 Character Definition Arrays

Each simple character set has a configuration file located in the `sql/share/charsets` directory. For a character set named `MYSYS`, the file is named `MYSET.xml`. It uses `<map>` array elements to list character set properties. `<map>` elements appear within these elements:

- `<ctype>` defines attributes for each character.

- `<lower>` and `<upper>` list the lowercase and uppercase characters.
- `<unicode>` maps 8-bit character values to Unicode values.
- `<collation>` elements indicate character ordering for comparison and sorting, one element per collation. Binary collations need no `<map>` element because the character codes themselves provide the ordering.

For a complex character set as implemented in a `ctype-MYSET.c` file in the `strings` directory, there are corresponding arrays: `ctype_MYSET[]`, `to_lower_MYSET[]`, and so forth. Not every complex character set has all of the arrays. See also the existing `ctype-*.c` files for examples. See the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

Most of the arrays are indexed by character value and have 256 elements. The `<ctype>` array is indexed by character value + 1 and has 257 elements. This is a legacy convention for handling EOF.

`<ctype>` array elements are bit values. Each element describes the attributes of a single character in the character set. Each attribute is associated with a bitmask, as defined in `include/m_ctype.h`:

```
#define _MY_U 01      /* Upper case */
#define _MY_L 02      /* Lower case */
#define _MY_NMR 04     /* Numeral (digit) */
#define _MY_SPC 010    /* Spacing character */
#define _MY_PNT 020    /* Punctuation */
#define _MY_CTR 040    /* Control character */
#define _MY_B 0100     /* Blank */
#define _MY_X 0200     /* hexadecimal digit */
```

The `<ctype>` value for a given character should be the union of the applicable bitmask values that describe the character. For example, 'A' is an uppercase character (`_MY_U`) as well as a hexadecimal digit (`_MY_X`), so its `ctype` value should be defined like this:

```
ctype['A'+1] = _MY_U | _MY_X = 01 | 0200 = 0201
```

The bitmask values in `m_ctype.h` are octal values, but the elements of the `<ctype>` array in `MYSET.xml` should be written as hexadecimal values.

The `<lower>` and `<upper>` arrays hold the lowercase and uppercase characters corresponding to each member of the character set. For example:

```
lower['A'] should contain 'a'
upper['a'] should contain 'A'
```

Each `<collation>` array indicates how characters should be ordered for comparison and sorting purposes. MySQL sorts characters based on the values of this information. In some cases, this is the same as the `<upper>` array, which means that sorting is case-insensitive. For more complicated sorting rules (for complex character sets), see the discussion of string collating in [Section 10.13.2, “String Collating Support for Complex Character Sets”](#).

10.13.2 String Collating Support for Complex Character Sets

For a simple character set named `MYSET`, sorting rules are specified in the `MYSET.xml` configuration file using `<map>` array elements within `<collation>` elements. If the sorting rules for your language are too complex to be handled with simple arrays, you must define string collating functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `big5`, `czech`, `gbk`, `sjis`, and `tis160` character sets. Take a look at the `MY_COLLATION_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

10.13.3 Multi-Byte Character Support for Complex Character Sets

If you want to add support for a new character set named *MYSET* that includes multibyte characters, you must use multibyte character functions in the `ctype-MYSET.c` source file in the `strings` directory.

The existing character sets provide the best documentation and examples to show how these functions are implemented. Look at the `ctype-*.c` files in the `strings` directory, such as the files for the `euc_kr`, `gb2312`, `gbk`, `sjis`, and `ujis` character sets. Take a look at the `MY_CHARSET_HANDLER` structures to see how they are used. See also the `CHARSET_INFO.txt` file in the `strings` directory for additional information.

10.14 Adding a Collation to a Character Set

A collation is a set of rules that defines how to compare and sort character strings. Each collation in MySQL belongs to a single character set. Every character set has at least one collation, and most have two or more collations.

A collation orders characters based on weights. Each character in a character set maps to a weight. Characters with equal weights compare as equal, and characters with unequal weights compare according to the relative magnitude of their weights.

The `WEIGHT_STRING()` function can be used to see the weights for the characters in a string. The value that it returns to indicate weights is a binary string, so it is convenient to use `HEX(WEIGHT_STRING(str))` to display the weights in printable form. The following example shows that weights do not differ for lettercase for the letters in `'AaBb'` if it is a nonbinary case-insensitive string, but do differ if it is a binary string:

```
mysql> SELECT HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci));
+-----+
| HEX(WEIGHT_STRING('AaBb' COLLATE latin1_swedish_ci)) |
+-----+
| 41414242 |
+-----+
mysql> SELECT HEX(WEIGHT_STRING(BINARY 'AaBb'));
+-----+
| HEX(WEIGHT_STRING(BINARY 'AaBb')) |
+-----+
| 41614262 |
+-----+
```

MySQL supports several collation implementations, as discussed in [Section 10.14.1, “Collation Implementation Types”](#). Some of these can be added to MySQL without recompiling:

- Simple collations for 8-bit character sets.
- UCA-based collations for Unicode character sets.
- Binary (`xxx_bin`) collations.

The following sections describe how to add user-defined collations of the first two types to existing character sets. All existing character sets already have a binary collation, so there is no need here to describe how to add one.

Warning

Redefining built-in collations is not supported and may result in unexpected server behavior.

Summary of the procedure for adding a new user-defined collation:

1. Choose a collation ID.

2. Add configuration information that names the collation and describes the character-ordering rules.
3. Restart the server.
4. Verify that the server recognizes the collation.

The instructions here cover only user-defined collations that can be added without recompiling MySQL. To add a collation that does require recompiling (as implemented by means of functions in a C source file), use the instructions in [Section 10.13, “Adding a Character Set”](#). However, instead of adding all the information required for a complete character set, just modify the appropriate files for an existing character set. That is, based on what is already present for the character set's current collations, add data structures, functions, and configuration information for the new collation.

Note

If you modify an existing user-defined collation, that may affect the ordering of rows for indexes on columns that use the collation. In this case, rebuild any such indexes to avoid problems such as incorrect query results. See [Section 2.11.13, “Rebuilding or Repairing Tables or Indexes”](#).

Additional Resources

- Example showing how to add a collation for full-text searches: [Section 12.10.7, “Adding a User-Defined Collation for Full-Text Indexing”](#)
- The Unicode Collation Algorithm (UCA) specification: <http://www.unicode.org/reports/tr10/>
- The Locale Data Markup Language (LDML) specification: <http://www.unicode.org/reports/tr35/>

10.14.1 Collation Implementation Types

MySQL implements several types of collations:

Simple collations for 8-bit character sets

This kind of collation is implemented using an array of 256 weights that defines a one-to-one mapping from character codes to weights. `latin1_swedish_ci` is an example. It is a case-insensitive collation, so the uppercase and lowercase versions of a character have the same weights and they compare as equal.

```
mysql> SET NAMES 'latin1' COLLATE 'latin1_swedish_ci';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT HEX(WEIGHT_STRING('a')), HEX(WEIGHT_STRING('A'));
+-----+-----+
| HEX(WEIGHT_STRING('a')) | HEX(WEIGHT_STRING('A')) |
+-----+-----+
| 41                      | 41                      |
+-----+-----+
1 row in set (0.01 sec)

mysql> SELECT 'a' = 'A';
+-----+
| 'a' = 'A' |
+-----+
|          1 |
+-----+
1 row in set (0.12 sec)
```

For implementation instructions, see [Section 10.14.3, “Adding a Simple Collation to an 8-Bit Character Set”](#).

Complex collations for 8-bit character sets

This kind of collation is implemented using functions in a C source file that define how to order characters, as described in [Section 10.13, “Adding a Character Set”](#).

Collations for non-Unicode multibyte character sets

For this type of collation, 8-bit (single-byte) and multibyte characters are handled differently. For 8-bit characters, character codes map to weights in case-insensitive fashion. (For example, the single-byte characters 'a' and 'A' both have a weight of 0x41.) For multibyte characters, there are two types of relationship between character codes and weights:

- Weights equal character codes. `sjis_japanese_ci` is an example of this kind of collation. The multibyte character 'ㇰ' has a character code of 0x82C0, and the weight is also 0x82C0.

```
mysql> CREATE TABLE t1
      (c1 VARCHAR(2) CHARACTER SET sjis COLLATE sjis_japanese_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x82C0);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1    | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a     | 61      | 41                     |
| A     | 41      | 41                     |
| ㇰ     | 82C0    | 82C0                   |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

- Character codes map one-to-one to weights, but a code is not necessarily equal to the weight. `gbk_chinese_ci` is an example of this kind of collation. The multibyte character '臙' has a character code of 0x81B0 but a weight of 0xC286.

```
mysql> CREATE TABLE t1
      (c1 VARCHAR(2) CHARACTER SET gbk COLLATE gbk_chinese_ci);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),(0x81B0);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1    | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a     | 61      | 41                     |
| A     | 41      | 41                     |
| 臙     | 81B0    | C286                   |
+-----+-----+-----+
3 rows in set (0.00 sec)
```

For implementation instructions, see [Section 10.13, “Adding a Character Set”](#).

Collations for Unicode multibyte character sets

Some of these collations are based on the Unicode Collation Algorithm (UCA), others are not.

Non-UCA collations have a one-to-one mapping from character code to weight. In MySQL, such collations are case-insensitive and accent-insensitive. `utf8_general_ci` is an example: 'a', 'A', 'À', and 'á' each have different character codes but all have a weight of 0x0041 and compare as equal.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_general_ci';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> CREATE TABLE t1
  (c1 CHAR(1) CHARACTER SET UTF8 COLLATE utf8_general_ci);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t1 VALUES ('a'),('A'),('Ä'),('á');
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c1, HEX(c1), HEX(WEIGHT_STRING(c1)) FROM t1;
+-----+-----+-----+
| c1 | HEX(c1) | HEX(WEIGHT_STRING(c1)) |
+-----+-----+-----+
| a | 61 | 0041 |
| A | 41 | 0041 |
| Ä | C380 | 0041 |
| á | C3A1 | 0041 |
+-----+-----+-----+
4 rows in set (0.00 sec)
```

UCA-based collations in MySQL have these properties:

- If a character has weights, each weight uses 2 bytes (16 bits).
- A character may have zero weights (or an empty weight). In this case, the character is ignorable. Example: "U+0000 NULL" does not have a weight and is ignorable.
- A character may have one weight. Example: 'a' has a weight of 0x0E33.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_unicode_ci';
Query OK, 0 rows affected (0.05 sec)

mysql> SELECT HEX('a'), HEX(WEIGHT_STRING('a'));
+-----+-----+
| HEX('a') | HEX(WEIGHT_STRING('a')) |
+-----+-----+
| 61 | 0E33 |
+-----+-----+
1 row in set (0.02 sec)
```

- A character may have many weights. This is an expansion. Example: The German letter 'ß' (SZ ligature, or SHARP S) has a weight of 0x0FEA0FEA.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_unicode_ci';
Query OK, 0 rows affected (0.11 sec)

mysql> SELECT HEX('ß'), HEX(WEIGHT_STRING('ß'));
+-----+-----+
| HEX('ß') | HEX(WEIGHT_STRING('ß')) |
+-----+-----+
| C39F | 0FEA0FEA |
+-----+-----+
1 row in set (0.00 sec)
```

- Many characters may have one weight. This is a contraction. Example: 'ch' is a single letter in Czech and has a weight of 0x0EE2.

```
mysql> SET NAMES 'utf8' COLLATE 'utf8_czech_ci';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT HEX('ch'), HEX(WEIGHT_STRING('ch'));
+-----+-----+
| HEX('ch') | HEX(WEIGHT_STRING('ch')) |
+-----+-----+
| 6368 | 0EE2 |
+-----+-----+
1 row in set (0.00 sec)
```

A many-characters-to-many-weights mapping is also possible (this is contraction with expansion), but is not supported by MySQL.

For implementation instructions, for a non-UCA collation, see [Section 10.13, “Adding a Character Set”](#). For a UCA collation, see [Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”](#).

Miscellaneous collations

There are also a few collations that do not fall into any of the previous categories.

10.14.2 Choosing a Collation ID

Each collation must have a unique ID. To add a collation, you must choose an ID value that is not currently used. MySQL supports two-byte collation IDs. The range of IDs from 1024 to 2047 is reserved for user-defined collations.

The collation ID that you choose will appear in these contexts:

- The `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table.
- The `Id` column of `SHOW COLLATION` output.
- The `charsetnr` member of the `MYSQL_FIELD` C API data structure.
- The `number` member of the `MY_CHARSET_INFO` data structure returned by the `mysql_get_character_set_info()` C API function.

To determine the largest currently used ID, issue the following statement:

```
mysql> SELECT MAX(ID) FROM INFORMATION_SCHEMA.COLLATIONS;
+-----+
| MAX(ID) |
+-----+
|      247 |
+-----+
```

To display a list of all currently used IDs, issue this statement:

```
mysql> SELECT ID FROM INFORMATION_SCHEMA.COLLATIONS ORDER BY ID;
+-----+
| ID |
+-----+
| 1 |
| 2 |
| ... |
| 52 |
| 53 |
| 57 |
| 58 |
| ... |
| 98 |
| 99 |
| 128 |
| 129 |
| ... |
| 247 |
+-----+
```

Warning

Before upgrading, you should save the configuration files that you change. If you upgrade in place, the process will replace the your modified files.

10.14.3 Adding a Simple Collation to an 8-Bit Character Set

This section describes how to add a simple collation for an 8-bit character set by writing the `<collation>` elements associated with a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. The example adds a collation named `latin1_test_ci` to the `latin1` character set.

1. Choose a collation ID, as shown in [Section 10.14.2, “Choosing a Collation ID”](#). The following steps use an ID of 1024.
2. Modify the `Index.xml` and `latin1.xml` configuration files. These files are located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value                               |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. For example:

```
<charset name="latin1">
...
  <collation name="latin1_test_ci" id="1024"/>
...
</charset>
```

4. In the `latin1.xml` configuration file, add a `<collation>` element that names the collation and that contains a `<map>` element that defines a character code-to-weight mapping table for character codes 0 to 255. Each value within the `<map>` element must be a number in hexadecimal format.

```
<collation name="latin1_test_ci">
<map>
  00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F
  10 11 12 13 14 15 16 17 18 19 1A 1B 1C 1D 1E 1F
  20 21 22 23 24 25 26 27 28 29 2A 2B 2C 2D 2E 2F
  30 31 32 33 34 35 36 37 38 39 3A 3B 3C 3D 3E 3F
  40 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
  50 51 52 53 54 55 56 57 58 59 5A 5B 5C 5D 5E 5F
  60 41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F
  50 51 52 53 54 55 56 57 58 59 5A 7B 7C 7D 7E 7F
  80 81 82 83 84 85 86 87 88 89 8A 8B 8C 8D 8E 8F
  90 91 92 93 94 95 96 97 98 99 9A 9B 9C 9D 9E 9F
  A0 A1 A2 A3 A4 A5 A6 A7 A8 A9 AA AB AC AD AE AF
  B0 B1 B2 B3 B4 B5 B6 B7 B8 B9 BA BB BC BD BE BF
  41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
  44 4E 4F 4F 4F 4F 5C D7 5C 55 55 55 59 59 DE DF
  41 41 41 41 5B 5D 5B 43 45 45 45 45 49 49 49 49
  44 4E 4F 4F 4F 4F 5C F7 5C 55 55 55 59 59 DE FF
</map>
</collation>
```

5. Restart the server and use this statement to verify that the collation is present:

```
mysql> SHOW COLLATION WHERE Collation = 'latin1_test_ci';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id   | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_test_ci | latin1 | 1024 |         |          | 1       |
+-----+-----+-----+-----+-----+-----+
```

10.14.4 Adding a UCA Collation to a Unicode Character Set

This section describes how to add a UCA collation for a Unicode character set by writing the `<collation>` element within a `<charset>` character set description in the MySQL `Index.xml` file. The procedure described here does not require recompiling MySQL. It uses a subset of the Locale Data Markup Language (LDML) specification, which is available at <http://www.unicode.org/reports/tr35/>. With this method, you need not define the entire collation. Instead, you begin with an existing “base” collation and describe the new collation in terms of how it differs from the base collation. The following table lists the base collations of the Unicode character sets for which UCA collations can be defined. It

is not possible to create user-defined UCA collations for `utf16le`; there is no `utf16le_unicode_ci` collation that would serve as the basis for such collations.

Table 10.4 MySQL Character Sets Available for User-Defined UCA Collations

Character Set	Base Collation
<code>utf8</code>	<code>utf8_unicode_ci</code>
<code>ucs2</code>	<code>ucs2_unicode_ci</code>
<code>utf16</code>	<code>utf16_unicode_ci</code>
<code>utf32</code>	<code>utf32_unicode_ci</code>

The following sections show how to add a collation that is defined using LDML syntax, and provide a summary of LDML rules supported in MySQL.

10.14.4.1 Defining a UCA Collation Using LDML Syntax

To add a UCA collation for a Unicode character set without recompiling MySQL, use the following procedure. If you are unfamiliar with the LDML rules used to describe the collation's sort characteristics, see [Section 10.14.4.2, “LDML Syntax Supported in MySQL”](#).

The example adds a collation named `utf8_phone_ci` to the `utf8` character set. The collation is designed for a scenario involving a Web application for which users post their names and phone numbers. Phone numbers can be given in very different formats:

```
+7-12345-67
+7-12-345-67
+7 12 345 67
+7 (12) 345 67
+71234567
```

The problem raised by dealing with these kinds of values is that the varying permissible formats make searching for a specific phone number very difficult. The solution is to define a new collation that reorders punctuation characters, making them ignorable.

1. Choose a collation ID, as shown in [Section 10.14.2, “Choosing a Collation ID”](#). The following steps use an ID of 1029.
2. To modify the `Index.xml` configuration file. This file is located in the directory named by the `character_sets_dir` system variable. You can check the variable value as follows, although the path name might be different on your system:

```
mysql> SHOW VARIABLES LIKE 'character_sets_dir';
+-----+-----+
| Variable_name | Value                                     |
+-----+-----+
| character_sets_dir | /user/local/mysql/share/mysql/charsets/ |
+-----+-----+
```

3. Choose a name for the collation and list it in the `Index.xml` file. In addition, you'll need to provide the collation ordering rules. Find the `<charset>` element for the character set to which the collation is being added, and add a `<collation>` element that indicates the collation name and ID, to associate the name with the ID. Within the `<collation>` element, provide a `<rules>` element containing the ordering rules:

```
<charset name="utf8">
...
  <collation name="utf8_phone_ci" id="1029">
    <rules>
      <reset>\u0000</reset>
      <i>\u0020</i> <!-- space -->
      <i>\u0028</i> <!-- left parenthesis -->
      <i>\u0029</i> <!-- right parenthesis -->
      <i>\u002B</i> <!-- plus -->
      <i>\u002D</i> <!-- hyphen -->
```

```

    </rules>
  </collation>
  ...
</charset>

```

- If you want a similar collation for other Unicode character sets, add other `<collation>` elements. For example, to define `ucs2_phone_ci`, add a `<collation>` element to the `<charset name="ucs2">` element. Remember that each collation must have its own unique ID.
- Restart the server and use this statement to verify that the collation is present:

```

mysql> SHOW COLLATION WHERE Collation = 'utf8_phone_ci';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id   | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| utf8_phone_ci | utf8    | 1029 |         |          |      8  |
+-----+-----+-----+-----+-----+-----+

```

Now test the collation to make sure that it has the desired properties.

Create a table containing some sample phone numbers using the new collation:

```

mysql> CREATE TABLE phonebook (
    name VARCHAR(64),
    phone VARCHAR(64) CHARACTER SET utf8 COLLATE utf8_phone_ci
);
Query OK, 0 rows affected (0.09 sec)

mysql> INSERT INTO phonebook VALUES ('Svoj','+7 912 800 80 02');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Hf','+7 (912) 800 80 04');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Bar','+7-912-800-80-01');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Ramil','(7912) 800 80 03');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO phonebook VALUES ('Sanja','+380 (912) 8008005');
Query OK, 1 row affected (0.00 sec)

```

Run some queries to see whether the ignored punctuation characters are in fact ignored for comparison and sorting:

```

mysql> SELECT * FROM phonebook ORDER BY phone;
+-----+-----+
| name | phone                |
+-----+-----+
| Sanja | +380 (912) 8008005   |
| Bar   | +7-912-800-80-01     |
| Svoj  | +7 912 800 80 02     |
| Ramil | (7912) 800 80 03     |
| Hf    | +7 (912) 800 80 04   |
+-----+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='+7(912)800-80-01';
+-----+-----+
| name | phone                |
+-----+-----+
| Bar   | +7-912-800-80-01     |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='79128008001';
+-----+-----+
| name | phone                |
+-----+-----+
| Bar   | +7-912-800-80-01     |
+-----+-----+

```

```

+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM phonebook WHERE phone='7 9 1 2 8 0 0 8 0 0 1';
+-----+-----+
| name | phone          |
+-----+-----+
| Bar  | +7-912-800-80-01 |
+-----+-----+
1 row in set (0.00 sec)

```

10.14.4.2 LDML Syntax Supported in MySQL

This section describes the LDML syntax that MySQL recognizes. This is a subset of the syntax described in the LDML specification available at <http://www.unicode.org/reports/tr35/>, which should be consulted for further information. MySQL recognizes a large enough subset of the syntax that, in many cases, it is possible to download a collation definition from the Unicode Common Locale Data Repository and paste the relevant part (that is, the part between the `<rules>` and `</rules>` tags) into the MySQL `Index.xml` file. The rules described here are all supported except that character sorting occurs only at the primary level. Rules that specify differences at secondary or higher sort levels are recognized (and thus can be included in collation definitions) but are treated as equality at the primary level.

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file. See [Section 10.14.4.3, “Diagnostics During Index.xml Parsing”](#).

Character Representation

Characters named in LDML rules can be written literally or in `\unnnn` format, where `nnnn` is the hexadecimal Unicode code point value. For example, `A` and `á` can be written literally or as `\u0041` and `\u00E1`. Within hexadecimal values, the digits `A` through `F` are not case-sensitive; `\u00E1` and `\u00e1` are equivalent. For UCA 4.0.0 collations, hexadecimal notation can be used only for characters in the Basic Multilingual Plane, not for characters outside the BMP range of `0000` to `FFFF`. For UCA 5.2.0 collations, hexadecimal notation can be used for any character.

The `Index.xml` file itself should be written using UTF-8 encoding.

Syntax Rules

LDML has reset rules and shift rules to specify character ordering. Orderings are given as a set of rules that begin with a reset rule that establishes an anchor point, followed by shift rules that indicate how characters sort relative to the anchor point.

- A `<reset>` rule does not specify any ordering in and of itself. Instead, it “resets” the ordering for subsequent shift rules to cause them to be taken in relation to a given character. Either of the following rules resets subsequent shift rules to be taken in relation to the letter `'A'`:

```

<reset>A</reset>

<reset>\u0041</reset>

```

- The `<p>`, `<s>`, and `<t>` shift rules define primary, secondary, and tertiary differences of a character from another character:
 - Use primary differences to distinguish separate letters.
 - Use secondary differences to distinguish accent variations.
 - Use tertiary differences to distinguish lettercase variations.

Either of these rules specifies a primary shift rule for the `'G'` character:

```

<p>G</p>

<p>\u0047</p>

```

- The `<i>` shift rule indicates that one character sorts identically to another. The following rules cause 'b' to sort the same as 'a':

```
<reset>a</reset>
<i>b</i>
```

- Abbreviated shift syntax specifies multiple shift rules using a single pair of tags. The following table shows the correspondence between abbreviated syntax rules and the equivalent nonabbreviated rules.

Table 10.5 Abbreviated Shift Syntax

Abbreviated Syntax	Nonabbreviated Syntax
<code><pc>xyz</pc></code>	<code><p>x</p><p>y</p><p>z</p></code>
<code><sc>xyz</sc></code>	<code><s>x</s><s>y</s><s>z</s></code>
<code><tc>xyz</tc></code>	<code><t>x</t><t>y</t><t>z</t></code>
<code><ic>xyz</ic></code>	<code><i>x</i><i>y</i><i>z</i></code>

- An expansion is a reset rule that establishes an anchor point for a multiple-character sequence. MySQL supports expansions 2 to 6 characters long. The following rules put 'z' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
<p>z</p>
```

- A contraction is a shift rule that sorts a multiple-character sequence. MySQL supports contractions 2 to 6 characters long. The following rules put the sequence of three characters 'xyz' greater at the primary level than 'a':

```
<reset>a</reset>
<p>xyz</p>
```

- Long expansions and long contractions can be used together. These rules put the sequence of three characters 'xyz' greater at the primary level than the sequence of three characters 'abc':

```
<reset>abc</reset>
<p>xyz</p>
```

- Normal expansion syntax uses `<x>` plus `<extend>` elements to specify an expansion. The following rules put the character 'k' greater at the secondary level than the sequence 'ch'. That is, 'k' behaves as if it expands to a character after 'c' followed by 'h':

```
<reset>c</reset>
<x><s>k</s><extend>h</extend></x>
```

This syntax permits long sequences. These rules sort the sequence 'ccs' greater at the tertiary level than the sequence 'cscs':

```
<reset>cs</reset>
<x><t>ccs</t><extend>cs</extend></x>
```

The LDML specification describes normal expansion syntax as “tricky.” See that specification for details.

- Previous context syntax uses `<x>` plus `<context>` elements to specify that the context before a character affects how it sorts. The following rules put '-' greater at the secondary level than 'a', but only when '-' occurs after 'b':

```
<reset>a</reset>
<x><context>b</context><s>-</s></x>
```

- Previous context syntax can include the `<extend>` element. These rules put 'def' greater at the primary level than 'aghi', but only when 'def' comes after 'abc':

```
<reset>a</reset>
<x><context>abc</context><p>def</p><extend>ghi</extend></x>
```

- Reset rules permit a `before` attribute. Normally, shift rules after a reset rule indicate characters that sort after the reset character. Shift rules after a reset rule that has the `before` attribute indicate characters that sort before the reset character. The following rules put the character 'b' immediately before 'a' at the primary level:

```
<reset before="primary">a</reset>
<p>b</p>
```

Permissible `before` attribute values specify the sort level by name or the equivalent numeric value:

```
<reset before="primary">
<reset before="1">

<reset before="secondary">
<reset before="2">

<reset before="tertiary">
<reset before="3">
```

- A reset rule can name a logical reset position rather than a literal character:

```
<first_tertiary_ignorable/>
<last_tertiary_ignorable/>
<first_secondary_ignorable/>
<last_secondary_ignorable/>
<first_primary_ignorable/>
<last_primary_ignorable/>
<first_variable/>
<last_variable/>
<first_non_ignorable/>
<last_non_ignorable/>
<first_trailing/>
<last_trailing/>
```

These rules put 'z' greater at the primary level than nonignorable characters that have a Default Unicode Collation Element Table (DUCET) entry and that are not CJK:

```
<reset><last_non_ignorable/></reset>
<p>z</p>
```

Logical positions have the code points shown in the following table.

Table 10.6 Logical Reset Position Code Points

Logical Position	Unicode 4.0.0 Code Point	Unicode 5.2.0 Code Point
<first_non_ignorable/>	U+02D0	U+02D0
<last_non_ignorable/>	U+A48C	U+1342E
<first_primary_ignorable/>	U+0332	U+0332
<last_primary_ignorable/>	U+20EA	U+101FD
<first_secondary_ignorable/>	U+0000	U+0000
<last_secondary_ignorable/>	U+FE73	U+FE73
<first_tertiary_ignorable/>	U+0000	U+0000
<last_tertiary_ignorable/>	U+FE73	U+FE73
<first_trailing/>	U+0000	U+0000
<last_trailing/>	U+0000	U+0000
<first_variable/>	U+0009	U+0009
<last_variable/>	U+2183	U+1D371

- The `<collation>` element permits a `shift-after-method` attribute that affects character weight calculation for shift rules. The attribute has these permitted values:
 - `simple`: Calculate character weights as for reset rules that do not have a `before` attribute. This is the default if the attribute is not given.
 - `expand`: Use expansions for shifts after reset rules.

Suppose that '0' and '1' have weights of 0E29 and 0E2A and we want to put all basic Latin letters between '0' and '1':

```
<reset>0</reset>
<pc>abcdefghijklmnopqrstuvwxyz</pc>
```

For simple shift mode, weights are calculated as follows:

```
'a' has weight 0E29+1
'b' has weight 0E29+2
'c' has weight 0E29+3
...
```

However, there are not enough vacant positions to put 26 characters between '0' and '1'. The result is that digits and letters are intermixed.

To solve this, use `shift-after-method="expand"`. Then weights are calculated like this:

```
'a' has weight [0E29][233D+1]
'b' has weight [0E29][233D+2]
'c' has weight [0E29][233D+3]
...
```

233D is the UCA 4.0.0 weight for character 0xA48C, which is the last nonignorable character (a sort of the greatest character in the collation, excluding CJK). UCA 5.2.0 is similar but uses 3ACA, for character 0x1342E.

MySQL-Specific LDML Extensions

An extension to LDML rules permits the `<collation>` element to include an optional `version` attribute in `<collation>` tags to indicate the UCA version on which the collation is based. If the `version` attribute is omitted, its default value is 4.0.0. For example, this specification indicates a collation that is based on UCA 5.2.0:

```
<collation id="nnn" name="utf8_xxx_ci" version="5.2.0">
...
</collation>
```

10.14.4.3 Diagnostics During Index.xml Parsing

The MySQL server generates diagnostics when it finds problems while parsing the `Index.xml` file:

- Unknown tags are written to the error log. For example, the following message results if a collation definition contains a `<aaa>` tag:

```
[Warning] Buffered warning: Unknown LDML tag:
'charsets/charset/collation/rules/aaa'
```

- If collation initialization is not possible, the server reports an “Unknown collation” error, and also generates warnings explaining the problems, such as in the previous example. In other cases, when a collation description is generally correct but contains some unknown tags, the collation is initialized and is available for use. The unknown parts are ignored, but a warning is generated in the error log.
- Problems with collations generate warnings that clients can display with `SHOW WARNINGS`. Suppose that a reset rule contains an expansion longer than the maximum supported length of 6 characters:

```
<reset>abcdefghi</reset>
```

```
<i>x</i>
```

An attempt to use the collation produces warnings:

```
mysql> SELECT _utf8'test' COLLATE utf8_test_ci;
ERROR 1273 (HY000): Unknown collation: 'utf8_test_ci'
mysql> SHOW WARNINGS;
```

Level	Code	Message
Error	1273	Unknown collation: 'utf8_test_ci'
Warning	1273	Expansion is too long at 'abcdefghi=x'

10.15 Character Set Configuration

The MySQL server has a compiled-in default character set and collation. To change these defaults, use the `--character-set-server` and `--collation-server` options when you start the server. See [Section 5.1.7, “Server Command Options”](#). The collation must be a legal collation for the default character set. To determine which collations are available for each character set, use the `SHOW COLLATION` statement or query the `INFORMATION_SCHEMA.COLLATIONS` table.

If you try to use a character set that is not compiled into your binary, you might run into the following problems:

- If your program uses an incorrect path to determine where the character sets are stored (which is typically the `share/mysql/charsets` or `share/charsets` directory under the MySQL installation directory), this can be fixed by using the `--character-sets-dir` option when you run the program. For example, to specify a directory to be used by MySQL client programs, list it in the `[client]` group of your option file. The examples given here show what the setting might look like for Unix or Windows, respectively:

```
[client]
character-sets-dir=/usr/local/mysql/share/mysql/charsets

[client]
character-sets-dir="C:/Program Files/MySQL/MySQL Server 8.0/share/charsets"
```

- If the character set is a complex character set that cannot be loaded dynamically, you must recompile the program with support for the character set.

For Unicode character sets, you can define collations without recompiling by using LDML notation. See [Section 10.14.4, “Adding a UCA Collation to a Unicode Character Set”](#).

- If the character set is a dynamic character set, but you do not have a configuration file for it, you should install the configuration file for the character set from a new MySQL distribution.
- If your character set index file (`Index.xml`) does not contain the name for the character set, your program displays an error message:

```
Character set 'charset_name' is not a compiled character set and is not
specified in the '/usr/share/mysql/charsets/Index.xml' file
```

To solve this problem, you should either get a new index file or manually add the name of any missing character sets to the current file.

You can force client programs to use specific character set as follows:

```
[client]
default-character-set=charset_name
```

This is normally unnecessary. However, when `character_set_system` differs from `character_set_server` or `character_set_client`, and you input characters manually (as database object identifiers, column values, or both), these may be displayed incorrectly in output from the client or the output itself may be formatted incorrectly. In such cases, starting the mysql client with

--default-character-set=system_character_set—that is, setting the client character set to match the system character set—should fix the problem.

10.16 MySQL Server Locale Support

The locale indicated by the `lc_time_names` system variable controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()`, and `MONTHNAME()` functions.

`lc_time_names` does not affect the `STR_TO_DATE()` or `GET_FORMAT()` function.

The `lc_time_names` value does not affect the result from `FORMAT()`, but this function takes an optional third parameter that enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable.

Locale names have language and region subtags listed by IANA (<http://www.iana.org/assignments/language-subtag-registry>) such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting, but you can set the value at server startup, or set the `GLOBAL` value at runtime if you have privileges sufficient to set global system variables; see [Section 5.1.9.1, “System Variable Privileges”](#). Any client can examine the value of `lc_time_names` or set its `SESSION` value to affect the locale for its own connection.

```
mysql> SET NAMES 'utf8';
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| en_US           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| Friday                | January                  |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| Friday Fri January Jan                   |
+-----+
1 row in set (0.00 sec)

mysql> SET lc_time_names = 'es_MX';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@lc_time_names;
+-----+
| @@lc_time_names |
+-----+
| es_MX           |
+-----+
1 row in set (0.00 sec)

mysql> SELECT DAYNAME('2010-01-01'), MONTHNAME('2010-01-01');
+-----+-----+
| DAYNAME('2010-01-01') | MONTHNAME('2010-01-01') |
+-----+-----+
| viernes                | enero                    |
+-----+-----+
1 row in set (0.00 sec)
```

```
mysql> SELECT DATE_FORMAT('2010-01-01','%W %a %M %b');
+-----+
| DATE_FORMAT('2010-01-01','%W %a %M %b') |
+-----+
| viernes vie enero ene                     |
+-----+
1 row in set (0.00 sec)
```

The day or month name for each of the affected functions is converted from `utf8` to the character set indicated by the `character_set_connection` system variable.

`lc_time_names` may be set to any of the following locale values. The set of locales supported by MySQL may differ from those supported by your operating system.

Locale Value	Meaning
<code>ar_AE</code>	Arabic - United Arab Emirates
<code>ar_BH</code>	Arabic - Bahrain
<code>ar_DZ</code>	Arabic - Algeria
<code>ar_EG</code>	Arabic - Egypt
<code>ar_IN</code>	Arabic - India
<code>ar_IQ</code>	Arabic - Iraq
<code>ar_JO</code>	Arabic - Jordan
<code>ar_KW</code>	Arabic - Kuwait
<code>ar_LB</code>	Arabic - Lebanon
<code>ar_LY</code>	Arabic - Libya
<code>ar_MA</code>	Arabic - Morocco
<code>ar_OM</code>	Arabic - Oman
<code>ar_QA</code>	Arabic - Qatar
<code>ar_SA</code>	Arabic - Saudi Arabia
<code>ar_SD</code>	Arabic - Sudan
<code>ar_SY</code>	Arabic - Syria
<code>ar_TN</code>	Arabic - Tunisia

Chapter 11 Data Types

Table of Contents

11.1	Numeric Data Types	1784
11.1.1	Numeric Data Type Syntax	1784
11.1.2	Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT	1788
11.1.3	Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC	1788
11.1.4	Floating-Point Types (Approximate Value) - FLOAT, DOUBLE	1789
11.1.5	Bit-Value Type - BIT	1789
11.1.6	Numeric Type Attributes	1789
11.1.7	Out-of-Range and Overflow Handling	1791
11.2	Date and Time Data Types	1792
11.2.1	Date and Time Data Type Syntax	1793
11.2.2	The DATE, DATETIME, and TIMESTAMP Types	1795
11.2.3	The TIME Type	1798
11.2.4	The YEAR Type	1799
11.2.5	Automatic Initialization and Updating for TIMESTAMP and DATETIME	1799
11.2.6	Fractional Seconds in Time Values	1803
11.2.7	Conversion Between Date and Time Types	1803
11.2.8	2-Digit Years in Dates	1804
11.3	String Data Types	1805
11.3.1	String Data Type Syntax	1805
11.3.2	The CHAR and VARCHAR Types	1808
11.3.3	The BINARY and VARBINARY Types	1810
11.3.4	The BLOB and TEXT Types	1811
11.3.5	The ENUM Type	1812
11.3.6	The SET Type	1816
11.4	Spatial Data Types	1818
11.4.1	Spatial Data Types	1819
11.4.2	The OpenGIS Geometry Model	1820
11.4.3	Supported Spatial Data Formats	1826
11.4.4	Geometry Well-Formedness and Validity	1829
11.4.5	Spatial Reference System Support	1829
11.4.6	Creating Spatial Columns	1831
11.4.7	Populating Spatial Columns	1831
11.4.8	Fetching Spatial Data	1832
11.4.9	Optimizing Spatial Analysis	1832
11.4.10	Creating Spatial Indexes	1833
11.4.11	Using Spatial Indexes	1834
11.5	The JSON Data Type	1835
11.6	Data Type Default Values	1851
11.7	Data Type Storage Requirements	1854
11.8	Choosing the Right Type for a Column	1858
11.9	Using Data Types from Other Database Engines	1858

MySQL supports [SQL](#) data types in several categories: numeric types, date and time types, string (character and byte) types, spatial types, and the [JSON](#) data type. This chapter provides an overview and more detailed description of the properties of the types in each category, and a summary of the data type storage requirements. The initial overviews are intentionally brief. Consult the more detailed descriptions for additional information about particular data types, such as the permissible formats in which you can specify values.

Data type descriptions use these conventions:

- For integer types, *M* indicates the maximum display width. For floating-point and fixed-point types, *M* is the total number of digits that can be stored (the precision). For string types, *M* is the maximum length. The maximum permissible value of *M* depends on the data type.
- *D* applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale). The maximum possible value is 30, but should be no greater than *M*–2.
- *fsp* applies to the `TIME`, `DATETIME`, and `TIMESTAMP` types and represents fractional seconds precision; that is, the number of digits following the decimal point for fractional parts of seconds. The *fsp* value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)
- Square brackets ([and]) indicate optional parts of type definitions.

11.1 Numeric Data Types

MySQL supports all standard SQL numeric data types. These types include the exact numeric data types (`INTEGER`, `SMALLINT`, `DECIMAL`, and `NUMERIC`), as well as the approximate numeric data types (`FLOAT`, `REAL`, and `DOUBLE PRECISION`). The keyword `INT` is a synonym for `INTEGER`, and the keywords `DEC` and `FIXED` are synonyms for `DECIMAL`. MySQL treats `DOUBLE` as a synonym for `DOUBLE PRECISION` (a nonstandard extension). MySQL also treats `REAL` as a synonym for `DOUBLE PRECISION` (a nonstandard variation), unless the `REAL_AS_FLOAT` SQL mode is enabled.

The `BIT` data type stores bit values and is supported for `MyISAM`, `MEMORY`, `InnoDB`, and `NDB` tables.

For information about how MySQL handles assignment of out-of-range values to columns and overflow during expression evaluation, see [Section 11.1.7, “Out-of-Range and Overflow Handling”](#).

For information about storage requirements of the numeric data types, see [Section 11.7, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on numeric values, see [Section 12.6, “Numeric Functions and Operators”](#). The data type used for the result of a calculation on numeric operands depends on the types of the operands and the operations performed on them. For more information, see [Section 12.6.1, “Arithmetic Operators”](#).

11.1.1 Numeric Data Type Syntax

For integer data types, *M* indicates the maximum display width. The maximum display width is 255. Display width is unrelated to the range of values a type can store, as described in [Section 11.1.6, “Numeric Type Attributes”](#).

For floating-point and fixed-point data types, *M* is the total number of digits that can be stored.

As of MySQL 8.0.17, the display width attribute is deprecated for integer data types and support for it will be removed in a future MySQL version.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute to the column.

As of MySQL 8.0.17, the `ZEROFILL` attribute is deprecated for numeric data types and support for it will be removed in a future MySQL version. Consider using an alternative means of producing the effect of this attribute. For example, applications could use the `LPAD()` function to zero-pad numbers up to the desired width, or they could store the formatted numbers in `CHAR` columns.

Numeric data types that permit the `UNSIGNED` attribute also permit `SIGNED`. However, these data types are signed by default, so the `SIGNED` attribute has no effect.

As of MySQL 8.0.17, the `UNSIGNED` attribute is deprecated for columns of type `FLOAT`, `DOUBLE`, and `DECIMAL` (and any synonyms) and support for it will be removed in a future MySQL version. Consider using a simple `CHECK` constraint instead for such columns.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

`SERIAL DEFAULT VALUE` in the definition of an integer column is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

Warning

When you use subtraction between integer values where one is of type `UNSIGNED`, the result is unsigned unless the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled. See [Section 12.11, “Cast Functions and Operators”](#).

- `BIT[(M)]`

A bit-value type. *M* indicates the number of bits per value, from 1 to 64. The default is 1 if *M* is omitted.

- `TINYINT[(M)] [UNSIGNED] [ZEROFILL]`

A very small integer. The signed range is `-128` to `127`. The unsigned range is `0` to `255`.

- `BOOL`, `BOOLEAN`

These types are synonyms for `TINYINT(1)`. A value of zero is considered false. Nonzero values are considered true:

```
mysql> SELECT IF(0, 'true', 'false');
+-----+
| IF(0, 'true', 'false') |
+-----+
| false                  |
+-----+

mysql> SELECT IF(1, 'true', 'false');
+-----+
| IF(1, 'true', 'false') |
+-----+
| true                   |
+-----+

mysql> SELECT IF(2, 'true', 'false');
+-----+
| IF(2, 'true', 'false') |
+-----+
| true                   |
+-----+
```

However, the values `TRUE` and `FALSE` are merely aliases for `1` and `0`, respectively, as shown here:

```
mysql> SELECT IF(0 = FALSE, 'true', 'false');
+-----+
| IF(0 = FALSE, 'true', 'false') |
+-----+
| true                           |
+-----+

mysql> SELECT IF(1 = TRUE, 'true', 'false');
+-----+
| IF(1 = TRUE, 'true', 'false') |
+-----+
| true                           |
+-----+

mysql> SELECT IF(2 = TRUE, 'true', 'false');
+-----+
| IF(2 = TRUE, 'true', 'false') |
+-----+
```

```
| false |
+-----+
mysql> SELECT IF(2 = FALSE, 'true', 'false');
+-----+
| IF(2 = FALSE, 'true', 'false') |
+-----+
| false |
+-----+
```

The last two statements display the results shown because 2 is equal to neither 1 nor 0.

- `SMALLINT[(M)] [UNSIGNED] [ZEROFILL]`

A small integer. The signed range is -32768 to 32767. The unsigned range is 0 to 65535.

- `MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]`

A medium-sized integer. The signed range is -8388608 to 8388607. The unsigned range is 0 to 16777215.

- `INT[(M)] [UNSIGNED] [ZEROFILL]`

A normal-size integer. The signed range is -2147483648 to 2147483647. The unsigned range is 0 to 4294967295.

- `INTEGER[(M)] [UNSIGNED] [ZEROFILL]`

This type is a synonym for `INT`.

- `BIGINT[(M)] [UNSIGNED] [ZEROFILL]`

A large integer. The signed range is -9223372036854775808 to 9223372036854775807. The unsigned range is 0 to 18446744073709551615.

`SERIAL` is an alias for `BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE`.

Some things you should be aware of with respect to `BIGINT` columns:

- All arithmetic is done using signed `BIGINT` or `DOUBLE` values, so you should not use unsigned big integers larger than 9223372036854775807 (63 bits) except with bit functions! If you do that, some of the last digits in the result may be wrong because of rounding errors when converting a `BIGINT` value to a `DOUBLE`.

MySQL can handle `BIGINT` in the following cases:

- When using integers to store large unsigned values in a `BIGINT` column.
- In `MIN(col_name)` or `MAX(col_name)`, where `col_name` refers to a `BIGINT` column.
- When using operators (+, -, *, and so on) where both operands are integers.
- You can always store an exact integer value in a `BIGINT` column by storing it using a string. In this case, MySQL performs a string-to-number conversion that involves no intermediate double-precision representation.
- The -, +, and * operators use `BIGINT` arithmetic when both operands are integer values. This means that if you multiply two big integers (or results from functions that return integers), you may get unexpected results when the result is larger than 9223372036854775807.
- `DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]`

A packed “exact” fixed-point number. *M* is the total number of digits (the precision) and *D* is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the

– sign are not counted in *M*. If *D* is 0, values have no decimal point or fractional part. The maximum number of digits (*M*) for `DECIMAL` is 65. The maximum number of supported decimals (*D*) is 30. If *D* is omitted, the default is 0. If *M* is omitted, the default is 10. (There is also a limit on how long the text of `DECIMAL` literals can be; see [Section 12.25.3, “Expression Handling”](#).)

`UNSIGNED`, if specified, disallows negative values. As of MySQL 8.0.17, the `UNSIGNED` attribute is deprecated for columns of type `DECIMAL` (and any synonyms) and support for it will be removed in a future MySQL version. Consider using a simple `CHECK` constraint instead for such columns.

All basic calculations (+, −, *, /) with `DECIMAL` columns are done with a precision of 65 digits.

- `DEC[(M[,D])] [UNSIGNED] [ZEROFILL], NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL], FIXED[(M[,D])] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DECIMAL`. The `FIXED` synonym is available for compatibility with other database systems.

- `FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]`

A small (single-precision) floating-point number. Permissible values are `−3.402823466E+38` to `−1.175494351E−38`, 0, and `1.175494351E−38` to `3.402823466E+38`. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits permitted by the hardware. A single-precision floating-point number is accurate to approximately 7 decimal places.

`FLOAT(M,D)` is a nonstandard MySQL extension. As of MySQL 8.0.17, this syntax is deprecated and support for it will be removed in a future MySQL version.

`UNSIGNED`, if specified, disallows negative values. As of MySQL 8.0.17, the `UNSIGNED` attribute is deprecated for columns of type `FLOAT` (and any synonyms) and support for it will be removed in a future MySQL version. Consider using a simple `CHECK` constraint instead for such columns.

Using `FLOAT` might give you some unexpected problems because all calculations in MySQL are done with double precision. See [Section B.3.4.7, “Solving Problems with No Matching Rows”](#).

- `FLOAT(p) [UNSIGNED] [ZEROFILL]`

A floating-point number. *p* represents the precision in bits, but MySQL uses this value only to determine whether to use `FLOAT` or `DOUBLE` for the resulting data type. If *p* is from 0 to 24, the data type becomes `FLOAT` with no *M* or *D* values. If *p* is from 25 to 53, the data type becomes `DOUBLE` with no *M* or *D* values. The range of the resulting column is the same as for the single-precision `FLOAT` or double-precision `DOUBLE` data types described earlier in this section.

`UNSIGNED`, if specified, disallows negative values. As of MySQL 8.0.17, the `UNSIGNED` attribute is deprecated for columns of type `FLOAT` (and any synonyms) and support for it will be removed in a future MySQL version. Consider using a simple `CHECK` constraint instead for such columns.

`FLOAT(p)` syntax is provided for ODBC compatibility.

- `DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]`

A normal-size (double-precision) floating-point number. Permissible values are `−1.7976931348623157E+308` to `−2.2250738585072014E−308`, 0, and `2.2250738585072014E−308` to `1.7976931348623157E+308`. These are the theoretical limits,

based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

M is the total number of digits and *D* is the number of digits following the decimal point. If *M* and *D* are omitted, values are stored to the limits permitted by the hardware. A double-precision floating-point number is accurate to approximately 15 decimal places.

`DOUBLE(M,D)` is a nonstandard MySQL extension. As of MySQL 8.0.17, this syntax is deprecated and support for it will be removed in a future MySQL version.

`UNSIGNED`, if specified, disallows negative values. As of MySQL 8.0.17, the `UNSIGNED` attribute is deprecated for columns of type `DOUBLE` (and any synonyms) and support for it will be removed in a future MySQL version. Consider using a simple `CHECK` constraint instead for such columns.

- `DOUBLE PRECISION[(M,D)] [UNSIGNED] [ZEROFILL], REAL[(M,D)] [UNSIGNED] [ZEROFILL]`

These types are synonyms for `DOUBLE`. Exception: If the `REAL_AS_FLOAT` SQL mode is enabled, `REAL` is a synonym for `FLOAT` rather than `DOUBLE`.

11.1.2 Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT

MySQL supports the SQL standard integer types `INTEGER` (or `INT`) and `SMALLINT`. As an extension to the standard, MySQL also supports the integer types `TINYINT`, `MEDIUMINT`, and `BIGINT`. The following table shows the required storage and range for each integer type.

Table 11.1 Required Storage and Range for Integer Types Supported by MySQL

Type	Storage (Bytes)	Minimum Value Signed	Minimum Value Unsigned	Maximum Value Signed	Maximum Value Unsigned
<code>TINYINT</code>	1	-128	0	127	255
<code>SMALLINT</code>	2	-32768	0	32767	65535
<code>MEDIUMINT</code>	3	-8388608	0	8388607	16777215
<code>INT</code>	4	-2147483648	0	2147483647	4294967295
<code>BIGINT</code>	8	-2 ⁶³	0	2 ⁶³ -1	2 ⁶⁴ -1

11.1.3 Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC

The `DECIMAL` and `NUMERIC` types store exact numeric data values. These types are used when it is important to preserve exact precision, for example with monetary data. In MySQL, `NUMERIC` is implemented as `DECIMAL`, so the following remarks about `DECIMAL` apply equally to `NUMERIC`.

MySQL stores `DECIMAL` values in binary format. See [Section 12.25, “Precision Math”](#).

In a `DECIMAL` column declaration, the precision and scale can be (and usually is) specified. For example:

```
salary DECIMAL(5,2)
```

In this example, 5 is the precision and 2 is the scale. The precision represents the number of significant digits that are stored for values, and the scale represents the number of digits that can be stored following the decimal point.

Standard SQL requires that `DECIMAL(5,2)` be able to store any value with five digits and two decimals, so values that can be stored in the `salary` column range from -999.99 to 999.99.

In standard SQL, the syntax `DECIMAL(M)` is equivalent to `DECIMAL(M, 0)`. Similarly, the syntax `DECIMAL` is equivalent to `DECIMAL(M, 0)`, where the implementation is permitted to decide the value of *M*. MySQL supports both of these variant forms of `DECIMAL` syntax. The default value of *M* is 10.

If the scale is 0, `DECIMAL` values contain no decimal point or fractional part.

The maximum number of digits for `DECIMAL` is 65, but the actual range for a given `DECIMAL` column can be constrained by the precision or scale for a given column. When such a column is assigned a value with more digits following the decimal point than are permitted by the specified scale, the value is converted to that scale. (The precise behavior is operating system-specific, but generally the effect is truncation to the permissible number of digits.)

11.1.4 Floating-Point Types (Approximate Value) - FLOAT, DOUBLE

The `FLOAT` and `DOUBLE` types represent approximate numeric data values. MySQL uses four bytes for single-precision values and eight bytes for double-precision values.

For `FLOAT`, the SQL standard permits an optional specification of the precision (but not the range of the exponent) in bits following the keyword `FLOAT` in parentheses; ; that is, `FLOAT(p)`. MySQL also supports this optional precision specification, but the precision value in `FLOAT(p)` is used only to determine storage size. A precision from 0 to 23 results in a 4-byte single-precision `FLOAT` column. A precision from 24 to 53 results in an 8-byte double-precision `DOUBLE` column.

MySQL permits a nonstandard syntax: `FLOAT(M,D)` or `REAL(M,D)` or `DOUBLE PRECISION(M,D)`. Here, (*M*,*D*) means that values can be stored with up to *M* digits in total, of which *D* digits may be after the decimal point. For example, a column defined as `FLOAT(7,4)` will look like `-999.9999` when displayed. MySQL performs rounding when storing values, so if you insert `999.00009` into a `FLOAT(7,4)` column, the approximate result is `999.0001`.

As of MySQL 8.0.17, the nonstandard `FLOAT(M,D)` and `DOUBLE(M,D)` syntax is deprecated and support for it will be removed in a future MySQL version.

Because floating-point values are approximate and not stored as exact values, attempts to treat them as exact in comparisons may lead to problems. They are also subject to platform or implementation dependencies. For more information, see [Section B.3.4.8, “Problems with Floating-Point Values”](#)

For maximum portability, code requiring storage of approximate numeric data values should use `FLOAT` or `DOUBLE PRECISION` with no specification of precision or number of digits.

11.1.5 Bit-Value Type - BIT

The `BIT` data type is used to store bit values. A type of `BIT(M)` enables storage of *M*-bit values. *M* can range from 1 to 64.

To specify bit values, `b'value'` notation can be used. *value* is a binary value written using zeros and ones. For example, `b'111'` and `b'10000000'` represent 7 and 128, respectively. See [Section 9.1.5, “Bit-Value Literals”](#).

If you assign a value to a `BIT(M)` column that is less than *M* bits long, the value is padded on the left with zeros. For example, assigning a value of `b'101'` to a `BIT(6)` column is, in effect, the same as assigning `b'000101'`.

NDB Cluster. The maximum combined size of all `BIT` columns used in a given `NDB` table must not exceed 4096 bits.

11.1.6 Numeric Type Attributes

MySQL supports an extension for optionally specifying the display width of integer data types in parentheses following the base keyword for the type. For example, `INT(4)` specifies an `INT` with a display width of four digits. This optional display width may be used by applications to display integer values having a width less than the width specified for the column by left-padding them with spaces.

(That is, this width is present in the metadata returned with result sets. Whether it is used is up to the application.)

The display width does *not* constrain the range of values that can be stored in the column. Nor does it prevent values wider than the column display width from being displayed correctly. For example, a column specified as `SMALLINT(3)` has the usual `SMALLINT` range of `-32768` to `32767`, and values outside the range permitted by three digits are displayed in full using more than three digits.

When used in conjunction with the optional (nonstandard) `ZEROFILL` attribute, the default padding of spaces is replaced with zeros. For example, for a column declared as `INT(4) ZEROFILL`, a value of `5` is retrieved as `0005`.

Note

The `ZEROFILL` attribute is ignored for columns involved in expressions or `UNION` queries.

If you store values larger than the display width in an integer column that has the `ZEROFILL` attribute, you may experience problems when MySQL generates temporary tables for some complicated joins. In these cases, MySQL assumes that the data values fit within the column display width.

As of MySQL 8.0.17, the `ZEROFILL` attribute is deprecated for numeric data types, as is the display width attribute for integer data types. Support for `ZEROFILL` and display widths for integer data types will be removed in a future MySQL version. Consider using an alternative means of producing the effect of these attributes. For example, applications could use the `LPAD()` function to zero-pad numbers up to the desired width, or they could store the formatted numbers in `CHAR` columns.

All integer types can have an optional (nonstandard) `UNSIGNED` attribute. An unsigned type can be used to permit only nonnegative numbers in a column or when you need a larger upper numeric range for the column. For example, if an `INT` column is `UNSIGNED`, the size of the column's range is the same but its endpoints shift up, from `-2147483648` and `2147483647` to `0` and `4294967295`.

Floating-point and fixed-point types also can be `UNSIGNED`. As with integer types, this attribute prevents negative values from being stored in the column. Unlike the integer types, the upper range of column values remains the same. As of MySQL 8.0.17, the `UNSIGNED` attribute is deprecated for columns of type `FLOAT`, `DOUBLE`, and `DECIMAL` (and any synonyms) and support for it will be removed in a future MySQL version. Consider using a simple `CHECK` constraint instead for such columns.

If you specify `ZEROFILL` for a numeric column, MySQL automatically adds the `UNSIGNED` attribute.

Integer or floating-point data types can have the `AUTO_INCREMENT` attribute. When you insert a value of `NULL` into an indexed `AUTO_INCREMENT` column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. (`AUTO_INCREMENT` sequences begin with `1`.)

Storing `0` into an `AUTO_INCREMENT` column has the same effect as storing `NULL`, unless the `NO_AUTO_VALUE_ON_ZERO` SQL mode is enabled.

Inserting `NULL` to generate `AUTO_INCREMENT` values requires that the column be declared `NOT NULL`. If the column is declared `NULL`, inserting `NULL` stores a `NULL`. When you insert any other value into an `AUTO_INCREMENT` column, the column is set to that value and the sequence is reset so that the next automatically generated value follows sequentially from the inserted value.

Negative values for `AUTO_INCREMENT` columns are not supported.

`CHECK` constraints cannot refer to columns that have the `AUTO_INCREMENT` attribute, nor can the `AUTO_INCREMENT` attribute be added to existing columns that are used in `CHECK` constraints.

As of MySQL 8.0.17, `AUTO_INCREMENT` support is deprecated for `FLOAT` and `DOUBLE` columns and will be removed in a future MySQL version. Consider removing the `AUTO_INCREMENT` attribute from such columns, or convert them to an integer type.

11.1.7 Out-of-Range and Overflow Handling

When MySQL stores a value in a numeric column that is outside the permissible range of the column data type, the result depends on the SQL mode in effect at the time:

- If strict SQL mode is enabled, MySQL rejects the out-of-range value with an error, and the insert fails, in accordance with the SQL standard.
- If no restrictive modes are enabled, MySQL clips the value to the appropriate endpoint of the column data type range and stores the resulting value instead.

When an out-of-range value is assigned to an integer column, MySQL stores the value representing the corresponding endpoint of the column data type range.

When a floating-point or fixed-point column is assigned a value that exceeds the range implied by the specified (or default) precision and scale, MySQL stores the value representing the corresponding endpoint of that range.

Suppose that a table `t1` has this definition:

```
CREATE TABLE t1 (i1 TINYINT, i2 TINYINT UNSIGNED);
```

With strict SQL mode enabled, an out of range error occurs:

```
mysql> SET sql_mode = 'TRADITIONAL';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
ERROR 1264 (22003): Out of range value for column 'i1' at row 1
mysql> SELECT * FROM t1;
Empty set (0.00 sec)
```

With strict SQL mode not enabled, clipping with warnings occurs:

```
mysql> SET sql_mode = '';
mysql> INSERT INTO t1 (i1, i2) VALUES(256, 256);
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1264 | Out of range value for column 'i1' at row 1 |
| Warning | 1264 | Out of range value for column 'i2' at row 1 |
+-----+-----+-----+
mysql> SELECT * FROM t1;
+-----+-----+
| i1 | i2 |
+-----+-----+
| 127 | 255 |
+-----+-----+
```

When strict SQL mode is not enabled, column-assignment conversions that occur due to clipping are reported as warnings for `ALTER TABLE`, `LOAD DATA`, `UPDATE`, and multiple-row `INSERT` statements. In strict mode, these statements fail, and some or all the values are not inserted or changed, depending on whether the table is a transactional table and other factors. For details, see [Section 5.1.11, “Server SQL Modes”](#).

Overflow during numeric expression evaluation results in an error. For example, the largest signed `BIGINT` value is 9223372036854775807, so the following expression produces an error:

```
mysql> SELECT 9223372036854775807 + 1;
ERROR 1690 (22003): BIGINT value is out of range in '(9223372036854775807 + 1)'
```

To enable the operation to succeed in this case, convert the value to unsigned;

```
mysql> SELECT CAST(9223372036854775807 AS UNSIGNED) + 1;
+-----+
| CAST(9223372036854775807 AS UNSIGNED) + 1 |
+-----+
| 9223372036854775808 |
+-----+
```

Whether overflow occurs depends on the range of the operands, so another way to handle the preceding expression is to use exact-value arithmetic because `DECIMAL` values have a larger range than integers:

```
mysql> SELECT 9223372036854775807.0 + 1;
+-----+
| 9223372036854775807.0 + 1 |
+-----+
|          9223372036854775808.0 |
+-----+
```

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
|                      -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

11.2 Date and Time Data Types

The date and time data types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`. Each temporal type has a range of valid values, as well as a “zero” value that may be used when you specify an invalid value that MySQL cannot represent. The `TIMESTAMP` and `DATETIME` types have special automatic updating behavior, described in [Section 11.2.5, “Automatic Initialization and Updating for `TIMESTAMP` and `DATETIME`”](#).

For information about storage requirements of the temporal data types, see [Section 11.7, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on temporal values, see [Section 12.7, “Date and Time Functions”](#).

Keep in mind these general considerations when working with date and time types:

- MySQL retrieves values for a given date or time type in a standard output format, but it attempts to interpret a variety of formats for input values that you supply (for example, when you specify a value to be assigned to or compared to a date or time type). For a description of the permitted formats for date and time types, see [Section 9.1.3, “Date and Time Literals”](#). It is expected that you supply valid values. Unpredictable results may occur if you use values in other formats.
- Although MySQL tries to interpret values in several formats, date parts must always be given in year-month-day order (for example, `'98-09-04'`), rather than in the month-day-year or day-month-year orders commonly used elsewhere (for example, `'09-04-98'`, `'04-09-98'`). To convert strings in other orders to year-month-day order, the `STR_TO_DATE()` function may be useful.
- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:

- Year values in the range 70–99 become 1970–1999.
- Year values in the range 00–69 become 2000–2069.

See also [Section 11.2.8, “2-Digit Years in Dates”](#).

- Conversion of values from one temporal type to another occurs according to the rules in [Section 11.2.7, “Conversion Between Date and Time Types”](#).
- MySQL automatically converts a date or time value to a number if the value is used in numeric context and vice versa.
- By default, when MySQL encounters a value for a date or time type that is out of range or otherwise invalid for the type, it converts the value to the “zero” value for that type. The exception is that out-of-range `TIME` values are clipped to the appropriate endpoint of the `TIME` range.
- By setting the SQL mode to the appropriate value, you can specify more exactly what kind of dates you want MySQL to support. (See [Section 5.1.11, “Server SQL Modes”](#).) You can get MySQL to accept certain dates, such as `'2009-11-31'`, by enabling the `ALLOW_INVALID_DATES` SQL mode. This is useful when you want to store a “possibly wrong” value which the user has specified (for example, in a web form) in the database for future processing. Under this mode, MySQL verifies only that the month is in the range from 1 to 12 and that the day is in the range from 1 to 31.
- MySQL permits you to store dates where the day or month and day are zero in a `DATE` or `DATETIME` column. This is useful for applications that need to store birthdates for which you may not know the exact date. In this case, you simply store the date as `'2009-00-00'` or `'2009-01-00'`. However, with dates such as these, you should not expect to get correct results for functions such as `DATE_SUB()` or `DATE_ADD()` that require complete dates. To disallow zero month or day parts in dates, enable the `NO_ZERO_IN_DATE` mode.
- MySQL permits you to store a “zero” value of `'0000-00-00'` as a “dummy date.” In some cases, this is more convenient than using `NULL` values, and uses less data and index space. To disallow `'0000-00-00'`, enable the `NO_ZERO_DATE` mode.
- “Zero” date or time values used through Connector/ODBC are converted automatically to `NULL` because ODBC cannot handle such values.

The following table shows the format of the “zero” value for each type. The “zero” values are special, but you can store or refer to them explicitly using the values shown in the table. You can also do this using the values `'0'` or `0`, which are easier to write. For temporal types that include a date part (`DATE`, `DATETIME`, and `TIMESTAMP`), use of these values may produce warning or errors. The precise behavior depends on which, if any, of the strict and `NO_ZERO_DATE` SQL modes are enabled; see [Section 5.1.11, “Server SQL Modes”](#).

Data Type	“Zero” Value
<code>DATE</code>	<code>'0000-00-00'</code>
<code>TIME</code>	<code>'00:00:00'</code>
<code>DATETIME</code>	<code>'0000-00-00 00:00:00'</code>
<code>TIMESTAMP</code>	<code>'0000-00-00 00:00:00'</code>
<code>YEAR</code>	<code>0000</code>

11.2.1 Date and Time Data Type Syntax

The date and time data types for representing temporal values are `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`.

For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

MySQL permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is `TIME`, `DATETIME`, or `TIMESTAMP`, and `fsp` is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6), ts TIMESTAMP(0));
```

The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

Any `TIMESTAMP` or `DATETIME` column in a table can have automatic initialization and updating properties; see [Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

- `DATE`

A date. The supported range is '1000-01-01' to '9999-12-31'. MySQL displays `DATE` values in 'YYYY-MM-DD' format, but permits assignment of values to `DATE` columns using either strings or numbers.

- `DATETIME[fsp]`

A date and time combination. The supported range is '1000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'. MySQL displays `DATETIME` values in 'YYYY-MM-DD hh:mm:ss[.fraction]' format, but permits assignment of values to `DATETIME` columns using either strings or numbers.

An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

Automatic initialization and updating to the current date and time for `DATETIME` columns can be specified using `DEFAULT` and `ON UPDATE` column definition clauses, as described in [Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

- `TIMESTAMP[fsp]`

A timestamp. The range is '1970-01-01 00:00:01.000000' UTC to '2038-01-19 03:14:07.999999' UTC. `TIMESTAMP` values are stored as the number of seconds since the epoch ('1970-01-01 00:00:00' UTC). A `TIMESTAMP` cannot represent the value '1970-01-01 00:00:00' because that is equivalent to 0 seconds from the epoch and the value 0 is reserved for representing '0000-00-00 00:00:00', the “zero” `TIMESTAMP` value.

An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

The way the server handles `TIMESTAMP` definitions depends on the value of the `explicit_defaults_for_timestamp` system variable (see [Section 5.1.8, “Server System Variables”](#)).

If `explicit_defaults_for_timestamp` is enabled, there is no automatic assignment of the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes to any `TIMESTAMP` column. They must be included explicitly in the column definition. Also, any `TIMESTAMP` not explicitly declared as `NOT NULL` permits `NULL` values.

If `explicit_defaults_for_timestamp` is disabled, the server handles `TIMESTAMP` as follows:

Unless specified otherwise, the first `TIMESTAMP` column in a table is defined to be automatically set to the date and time of the most recent modification if not explicitly assigned a value. This makes `TIMESTAMP` useful for recording the timestamp of an `INSERT` or `UPDATE` operation. You can also set

any `TIMESTAMP` column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

Automatic initialization and updating to the current date and time can be specified using `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` column definition clauses. By default, the first `TIMESTAMP` column has these properties, as previously noted. However, any `TIMESTAMP` column in a table can be defined to have these properties.

- `TIME[(fsp)]`

A time. The range is `'-838:59:59.000000'` to `'838:59:59.000000'`. MySQL displays `TIME` values in `'hh:mm:ss[.fraction]'` format, but permits assignment of values to `TIME` columns using either strings or numbers.

An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

- `YEAR[(4)]`

A year in 4-digit format. MySQL displays `YEAR` values in `YYYY` format, but permits assignment of values to `YEAR` columns using either strings or numbers. Values display as `1901` to `2155`, or `0000`.

For additional information about `YEAR` display format and interpretation of input values, see [Section 11.2.4, “The YEAR Type”](#).

Note

As of MySQL 8.0.19, the `YEAR(4)` data type with an explicit display width is deprecated and support for it will be removed in a future MySQL version. Instead, use `YEAR` without a display width, which has the same meaning.

MySQL 8.0 does not support the 2-digit `YEAR(2)` data type permitted in older versions of MySQL. For instructions on converting to 4-digit `YEAR`, see [2-Digit YEAR\(2\) Limitations and Migrating to 4-Digit YEAR in MySQL 5.7 Reference Manual](#).

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

11.2.2 The DATE, DATETIME, and TIMESTAMP Types

The `DATE`, `DATETIME`, and `TIMESTAMP` types are related. This section describes their characteristics, how they are similar, and how they differ. MySQL recognizes `DATE`, `DATETIME`, and `TIMESTAMP` values in several formats, described in [Section 9.1.3, “Date and Time Literals”](#). For the `DATE` and `DATETIME` range descriptions, “supported” means that although earlier values might work, there is no guarantee.

The `DATE` type is used for values with a date part but no time part. MySQL retrieves and displays `DATE` values in `'YYYY-MM-DD'` format. The supported range is `'1000-01-01'` to `'9999-12-31'`.

The `DATETIME` type is used for values that contain both date and time parts. MySQL retrieves and displays `DATETIME` values in `'YYYY-MM-DD hh:mm:ss'` format. The supported range is `'1000-01-01 00:00:00'` to `'9999-12-31 23:59:59'`.

The `TIMESTAMP` data type is used for values that contain both date and time parts. `TIMESTAMP` has a range of `'1970-01-01 00:00:01'` UTC to `'2038-01-19 03:14:07'` UTC.

A `DATETIME` or `TIMESTAMP` value can include a trailing fractional seconds part in up to microseconds (6 digits) precision. In particular, any fractional part in a value inserted into a `DATETIME` or `TIMESTAMP` column is stored rather than discarded. With the fractional part included, the format for these values is `'YYYY-MM-DD hh:mm:ss[.fraction]'`, the range for `DATETIME` values is `'1000-01-01 00:00:00.000000'` to `'9999-12-31 23:59:59.999999'`, and the range for `TIMESTAMP` values is `'1970-01-01 00:00:01.000000'` to `'2038-01-19 03:14:07.999999'`. The fractional part should always be separated from the rest of the time by a decimal point; no other fractional seconds delimiter is recognized. For information about fractional seconds support in MySQL, see [Section 11.2.6, “Fractional Seconds in Time Values”](#).

The `TIMESTAMP` and `DATETIME` data types offer automatic initialization and updating to the current date and time. For more information, see [Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

MySQL converts `TIMESTAMP` values from the current time zone to UTC for storage, and back from UTC to the current time zone for retrieval. (This does not occur for other types such as `DATETIME`.) By default, the current time zone for each connection is the server's time. The time zone can be set on a per-connection basis. As long as the time zone setting remains constant, you get back the same value you store. If you store a `TIMESTAMP` value, and then change the time zone and retrieve the value, the retrieved value is different from the value you stored. This occurs because the same time zone was not used for conversion in both directions. The current time zone is available as the value of the `time_zone` system variable. For more information, see [Section 5.1.14, “MySQL Server Time Zone Support”](#).

As of MySQL 8.0.19, you can specify a time zone offset when inserting `TIMESTAMP` and `DATETIME` values into a table. The offset is appended to the date part of a datetime literal, with no intervening spaces, and uses the same format used for setting the `time_zone` system variable, with the following exceptions:

- For hour values less than 10, a leading zero is required.
- The value `'-00:00'` is rejected.
- Time zone names such as `'EET'` and `'Asia/Shanghai'` cannot be used; `'SYSTEM'` also cannot be used in this context.

The value inserted must not have a zero for the month part, the day part, or both parts. This is enforced beginning with MySQL 8.0.22, regardless of the server SQL mode setting.

This example illustrates inserting datetime values with time zone offsets into `TIMESTAMP` and `DATETIME` columns using different `time_zone` settings, and then retrieving them:

```
mysql> CREATE TABLE ts (
->     id INTEGER NOT NULL AUTO_INCREMENT PRIMARY KEY,
->     col TIMESTAMP NOT NULL
-> ) AUTO_INCREMENT = 1;

mysql> CREATE TABLE dt (
->     id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->     col DATETIME NOT NULL
-> ) AUTO_INCREMENT = 1;

mysql> SET @@time_zone = 'SYSTEM';

mysql> INSERT INTO ts (col) VALUES ('2020-01-01 10:10:10'),
->     ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');

mysql> SET @@time_zone = '+00:00';

mysql> INSERT INTO ts (col) VALUES ('2020-01-01 10:10:10'),
->     ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');

mysql> SET @@time_zone = 'SYSTEM';
```

```
mysql> INSERT INTO dt (col) VALUES ('2020-01-01 10:10:10'),
->   ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');

mysql> SET @@time_zone = '+00:00';

mysql> INSERT INTO dt (col) VALUES ('2020-01-01 10:10:10'),
->   ('2020-01-01 10:10:10+05:30'), ('2020-01-01 10:10:10-08:00');

mysql> SET @@time_zone = 'SYSTEM';

mysql> SELECT @@system_time_zone;
+-----+
| @@system_time_zone |
+-----+
| EST                |
+-----+

mysql> SELECT col, UNIX_TIMESTAMP(col) FROM dt ORDER BY id;
+-----+-----+
| col                | UNIX_TIMESTAMP(col) |

+-----+-----+
| col                | UNIX_TIMESTAMP(col) |
+-----+-----+
| 2020-01-01 10:10:10 | 1577891410          |
| 2019-12-31 23:40:10 | 1577853610          |
| 2020-01-01 13:10:10 | 1577902210          |
| 2020-01-01 05:10:10 | 1577873410          |
| 2019-12-31 23:40:10 | 1577853610          |
| 2020-01-01 13:10:10 | 1577902210          |
+-----+-----+
```

The offset is not displayed when selecting a datetime value, even if one was used when inserting it.

The range of supported offset values is `-14:00` to `+14:00`, inclusive.

Datetime literals that include time zone offsets are accepted as parameter values by prepared statements.

Invalid `DATE`, `DATETIME`, or `TIMESTAMP` values are converted to the “zero” value of the appropriate type (`'0000-00-00'` or `'0000-00-00 00:00:00'`), if the SQL mode permits this conversion. The precise behavior depends on which if any of strict SQL mode and the `NO_ZERO_DATE` SQL mode are enabled; see [Section 5.1.11, “Server SQL Modes”](#).

In MySQL 8.0.22 and later, you can convert `TIMESTAMP` values to UTC `DATETIME` values when retrieving them using `CAST()` with the `AT TIME ZONE` operator, as shown here:

```
mysql> SELECT col,
>   CAST(col AT TIME ZONE INTERVAL '+00:00' AS DATETIME) AS ut
>   FROM ts ORDER BY id;
+-----+-----+
| col                | ut                |
+-----+-----+
| 2020-01-01 10:10:10 | 2020-01-01 15:10:10 |
| 2019-12-31 23:40:10 | 2020-01-01 04:40:10 |
| 2020-01-01 13:10:10 | 2020-01-01 18:10:10 |
| 2020-01-01 10:10:10 | 2020-01-01 15:10:10 |
| 2020-01-01 04:40:10 | 2020-01-01 09:40:10 |
| 2020-01-01 18:10:10 | 2020-01-01 23:10:10 |
+-----+-----+
```

For complete information regarding syntax and additional examples, see the description of the [CAST\(\)](#) function.

Be aware of certain properties of date value interpretation in MySQL:

- MySQL permits a “relaxed” format for values specified as strings, in which any punctuation character may be used as the delimiter between date parts or time parts. In some cases, this syntax can be deceiving. For example, a value such as `'10:11:12'` might look like a time value because of the `:`, but is interpreted as the year `'2010-11-12'` if used in date context. The value `'10:45:15'` is converted to `'0000-00-00'` because `'45'` is not a valid month.

The only delimiter recognized between a date and time part and a fractional seconds part is the decimal point.

- The server requires that month and day values be valid, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable [ALLOW_INVALID_DATES](#). See [Section 5.1.11, “Server SQL Modes”](#), for more information.
- MySQL does not accept [TIMESTAMP](#) values that include a zero in the day or month column or values that are not a valid date. The sole exception to this rule is the special “zero” value `'0000-00-00 00:00:00'`, if the SQL mode permits this value. The precise behavior depends on which if any of strict SQL mode and the [NO_ZERO_DATE](#) SQL mode are enabled; see [Section 5.1.11, “Server SQL Modes”](#).
- Dates containing 2-digit year values are ambiguous because the century is unknown. MySQL interprets 2-digit year values using these rules:
 - Year values in the range `00-69` become `2000-2069`.
 - Year values in the range `70-99` become `1970-1999`.

See also [Section 11.2.8, “2-Digit Years in Dates”](#).

11.2.3 The TIME Type

MySQL retrieves and displays [TIME](#) values in `'hh:mm:ss'` format (or `'hhh:mm:ss'` format for large hours values). [TIME](#) values may range from `'-838:59:59'` to `'838:59:59'`. The hours part may be so large because the [TIME](#) type can be used not only to represent a time of day (which must be less than 24 hours), but also elapsed time or a time interval between two events (which may be much greater than 24 hours, or even negative).

MySQL recognizes [TIME](#) values in several formats, some of which can include a trailing fractional seconds part in up to microseconds (6 digits) precision. See [Section 9.1.3, “Date and Time Literals”](#). For information about fractional seconds support in MySQL, see [Section 11.2.6, “Fractional Seconds in Time Values”](#). In particular, any fractional part in a value inserted into a [TIME](#) column is stored rather than discarded. With the fractional part included, the range for [TIME](#) values is `'-838:59:59.000000'` to `'838:59:59.000000'`.

Be careful about assigning abbreviated values to a [TIME](#) column. MySQL interprets abbreviated [TIME](#) values with colons as time of the day. That is, `'11:12'` means `'11:12:00'`, not `'00:11:12'`. MySQL interprets abbreviated values without colons using the assumption that the two rightmost digits represent seconds (that is, as elapsed time rather than as time of day). For example, you might think of `'1112'` and `1112` as meaning `'11:12:00'` (12 minutes after 11 o'clock), but MySQL interprets them as `'00:11:12'` (11 minutes, 12 seconds). Similarly, `'12'` and `12` are interpreted as `'00:00:12'`.

The only delimiter recognized between a time part and a fractional seconds part is the decimal point.

By default, values that lie outside the [TIME](#) range but are otherwise valid are clipped to the closest endpoint of the range. For example, `'-850:00:00'` and `'850:00:00'` are converted to

'-838:59:59' and '838:59:59'. Invalid `TIME` values are converted to '00:00:00'. Note that because '00:00:00' is itself a valid `TIME` value, there is no way to tell, from a value of '00:00:00' stored in a table, whether the original value was specified as '00:00:00' or whether it was invalid.

For more restrictive treatment of invalid `TIME` values, enable strict SQL mode to cause errors to occur. See [Section 5.1.11, “Server SQL Modes”](#).

11.2.4 The YEAR Type

The `YEAR` type is a 1-byte type used to represent year values. It can be declared as `YEAR` with an implicit display width of 4 characters, or equivalently as `YEAR(4)` with an explicit display width.

Note

As of MySQL 8.0.19, the `YEAR(4)` data type with an explicit display width is deprecated and support for it will be removed in a future MySQL version. Instead, use `YEAR` without a display width, which has the same meaning.

MySQL 8.0 does not support the 2-digit `YEAR(2)` data type permitted in older versions of MySQL. For instructions on converting to 4-digit `YEAR`, see [2-Digit YEAR\(2\) Limitations and Migrating to 4-Digit YEAR](#) in [MySQL 5.7 Reference Manual](#).

MySQL displays `YEAR` values in `YYYY` format, with a range of 1901 to 2155, and 0000.

`YEAR` accepts input values in a variety of formats:

- As 4-digit strings in the range '1901' to '2155'.
- As 4-digit numbers in the range 1901 to 2155.
- As 1- or 2-digit strings in the range '0' to '99'. MySQL converts values in the ranges '0' to '69' and '70' to '99' to `YEAR` values in the ranges 2000 to 2069 and 1970 to 1999.
- As 1- or 2-digit numbers in the range 0 to 99. MySQL converts values in the ranges 1 to 69 and 70 to 99 to `YEAR` values in the ranges 2001 to 2069 and 1970 to 1999.

The result of inserting a numeric 0 has a display value of 0000 and an internal value of 0000. To insert zero and have it be interpreted as 2000, specify it as a string '0' or '00'.

- As the result of functions that return a value that is acceptable in `YEAR` context, such as `NOW()`.

If strict SQL mode is not enabled, MySQL converts invalid `YEAR` values to 0000. In strict SQL mode, attempting to insert an invalid `YEAR` value produces an error.

See also [Section 11.2.8, “2-Digit Years in Dates”](#).

11.2.5 Automatic Initialization and Updating for TIMESTAMP and DATETIME

`TIMESTAMP` and `DATETIME` columns can be automatically initialized and updated to the current date and time (that is, the current timestamp).

For any `TIMESTAMP` or `DATETIME` column in a table, you can assign the current timestamp as the default value, the auto-update value, or both:

- An auto-initialized column is set to the current timestamp for inserted rows that specify no value for the column.
- An auto-updated column is automatically updated to the current timestamp when the value of any other column in the row is changed from its current value. An auto-updated column remains unchanged if all other columns are set to their current values. To prevent an auto-updated column

from updating when other columns change, explicitly set it to its current value. To update an auto-updated column even when other columns do not change, explicitly set it to the value it should have (for example, set it to `CURRENT_TIMESTAMP`).

In addition, if the `explicit_defaults_for_timestamp` system variable is disabled, you can initialize or update any `TIMESTAMP` (but not `DATETIME`) column to the current date and time by assigning it a `NULL` value, unless it has been defined with the `NULL` attribute to permit `NULL` values.

To specify automatic properties, use the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses in column definitions. The order of the clauses does not matter. If both are present in a column definition, either can occur first. Any of the synonyms for `CURRENT_TIMESTAMP` have the same meaning as `CURRENT_TIMESTAMP`. These are `CURRENT_TIMESTAMP()`, `NOW()`, `LOCALTIME`, `LOCALTIME()`, `LOCALTIMESTAMP`, and `LOCALTIMESTAMP()`.

Use of `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` is specific to `TIMESTAMP` and `DATETIME`. The `DEFAULT` clause also can be used to specify a constant (nonautomatic) default value (for example, `DEFAULT 0` or `DEFAULT '2000-01-01 00:00:00'`).

Note

The following examples use `DEFAULT 0`, a default that can produce warnings or errors depending on whether strict SQL mode or the `NO_ZERO_DATE` SQL mode is enabled. Be aware that the `TRADITIONAL` SQL mode includes strict mode and `NO_ZERO_DATE`. See [Section 5.1.11, “Server SQL Modes”](#).

`TIMESTAMP` or `DATETIME` column definitions can specify the current timestamp for both the default and auto-update values, for one but not the other, or for neither. Different columns can have different combinations of automatic properties. The following rules describe the possibilities:

- With both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP`, the column has the current timestamp for its default value and is automatically updated to the current timestamp.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
);
```

- With a `DEFAULT` clause but no `ON UPDATE CURRENT_TIMESTAMP` clause, the column has the given default value and is not automatically updated to the current timestamp.

The default depends on whether the `DEFAULT` clause specifies `CURRENT_TIMESTAMP` or a constant value. With `CURRENT_TIMESTAMP`, the default is the current timestamp.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
  dt DATETIME DEFAULT CURRENT_TIMESTAMP
);
```

With a constant, the default is the given value. In this case, the column has no automatic properties at all.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT 0,
  dt DATETIME DEFAULT 0
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause and a constant `DEFAULT` clause, the column is automatically updated to the current timestamp and has the given constant default value.

```
CREATE TABLE t1 (
  ts TIMESTAMP DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP,
  dt DATETIME DEFAULT 0 ON UPDATE CURRENT_TIMESTAMP
);
```

- With an `ON UPDATE CURRENT_TIMESTAMP` clause but no `DEFAULT` clause, the column is automatically updated to the current timestamp but does not have the current timestamp for its default value.

The default in this case is type dependent. `TIMESTAMP` has a default of 0 unless defined with the `NULL` attribute, in which case the default is `NULL`.

```
CREATE TABLE t1 (
  ts1 TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,      -- default 0
  ts2 TIMESTAMP NULL ON UPDATE CURRENT_TIMESTAMP -- default NULL
);
```

`DATETIME` has a default of `NULL` unless defined with the `NOT NULL` attribute, in which case the default is 0.

```
CREATE TABLE t1 (
  dt1 DATETIME ON UPDATE CURRENT_TIMESTAMP,      -- default NULL
  dt2 DATETIME NOT NULL ON UPDATE CURRENT_TIMESTAMP -- default 0
);
```

`TIMESTAMP` and `DATETIME` columns have no automatic properties unless they are specified explicitly, with this exception: If the `explicit_defaults_for_timestamp` system variable is disabled, the *first* `TIMESTAMP` column has both `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` if neither is specified explicitly. To suppress automatic properties for the first `TIMESTAMP` column, use one of these strategies:

- Enable the `explicit_defaults_for_timestamp` system variable. In this case, the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` clauses that specify automatic initialization and updating are available, but are not assigned to any `TIMESTAMP` column unless explicitly included in the column definition.
- Alternatively, if `explicit_defaults_for_timestamp` is disabled, do either of the following:
 - Define the column with a `DEFAULT` clause that specifies a constant default value.
 - Specify the `NULL` attribute. This also causes the column to permit `NULL` values, which means that you cannot assign the current timestamp by setting the column to `NULL`. Assigning `NULL` sets the column to `NULL`, not the current timestamp. To assign the current timestamp, set the column to `CURRENT_TIMESTAMP` or a synonym such as `NOW()`.

Consider these table definitions:

```
CREATE TABLE t1 (
  ts1 TIMESTAMP DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
      ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t2 (
  ts1 TIMESTAMP NULL,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
      ON UPDATE CURRENT_TIMESTAMP);
CREATE TABLE t3 (
  ts1 TIMESTAMP NULL DEFAULT 0,
  ts2 TIMESTAMP DEFAULT CURRENT_TIMESTAMP
      ON UPDATE CURRENT_TIMESTAMP);
```

The tables have these properties:

- In each table definition, the first `TIMESTAMP` column has no automatic initialization or updating.
- The tables differ in how the `ts1` column handles `NULL` values. For `t1`, `ts1` is `NOT NULL` and assigning it a value of `NULL` sets it to the current timestamp. For `t2` and `t3`, `ts1` permits `NULL` and assigning it a value of `NULL` sets it to `NULL`.
- `t2` and `t3` differ in the default value for `ts1`. For `t2`, `ts1` is defined to permit `NULL`, so the default is also `NULL` in the absence of an explicit `DEFAULT` clause. For `t3`, `ts1` permits `NULL` but has an explicit default of 0.

If a `TIMESTAMP` or `DATETIME` column definition includes an explicit fractional seconds precision value anywhere, the same value must be used throughout the column definition. This is permitted:

```
CREATE TABLE t1 (
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP(6) ON UPDATE CURRENT_TIMESTAMP(6)
);
```

This is not permitted:

```
CREATE TABLE t1 (
  ts TIMESTAMP(6) DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP(3)
);
```

TIMESTAMP Initialization and the NULL Attribute

If the `explicit_defaults_for_timestamp` system variable is disabled, `TIMESTAMP` columns by default are `NOT NULL`, cannot contain `NULL` values, and assigning `NULL` assigns the current timestamp. To permit a `TIMESTAMP` column to contain `NULL`, explicitly declare it with the `NULL` attribute. In this case, the default value also becomes `NULL` unless overridden with a `DEFAULT` clause that specifies a different default value. `DEFAULT NULL` can be used to explicitly specify `NULL` as the default value. (For a `TIMESTAMP` column not declared with the `NULL` attribute, `DEFAULT NULL` is invalid.) If a `TIMESTAMP` column permits `NULL` values, assigning `NULL` sets it to `NULL`, not to the current timestamp.

The following table contains several `TIMESTAMP` columns that permit `NULL` values:

```
CREATE TABLE t
(
  ts1 TIMESTAMP NULL DEFAULT NULL,
  ts2 TIMESTAMP NULL DEFAULT 0,
  ts3 TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP
);
```

A `TIMESTAMP` column that permits `NULL` values does *not* take on the current timestamp at insert time except under one of the following conditions:

- Its default value is defined as `CURRENT_TIMESTAMP` and no value is specified for the column
- `CURRENT_TIMESTAMP` or any of its synonyms such as `NOW()` is explicitly inserted into the column

In other words, a `TIMESTAMP` column defined to permit `NULL` values auto-initializes only if its definition includes `DEFAULT CURRENT_TIMESTAMP`:

```
CREATE TABLE t (ts TIMESTAMP NULL DEFAULT CURRENT_TIMESTAMP);
```

If the `TIMESTAMP` column permits `NULL` values but its definition does not include `DEFAULT CURRENT_TIMESTAMP`, you must explicitly insert a value corresponding to the current date and time. Suppose that tables `t1` and `t2` have these definitions:

```
CREATE TABLE t1 (ts TIMESTAMP NULL DEFAULT '0000-00-00 00:00:00');
CREATE TABLE t2 (ts TIMESTAMP NULL DEFAULT NULL);
```

To set the `TIMESTAMP` column in either table to the current timestamp at insert time, explicitly assign it that value. For example:

```
INSERT INTO t2 VALUES (CURRENT_TIMESTAMP);
INSERT INTO t1 VALUES (NOW());
```

If the `explicit_defaults_for_timestamp` system variable is enabled, `TIMESTAMP` columns permit `NULL` values only if declared with the `NULL` attribute. Also, `TIMESTAMP` columns do not permit assigning `NULL` to assign the current timestamp, whether declared with the `NULL` or `NOT NULL` attribute. To assign the current timestamp, set the column to `CURRENT_TIMESTAMP` or a synonym such as `NOW()`.

11.2.6 Fractional Seconds in Time Values

MySQL has fractional seconds support for [TIME](#), [DATETIME](#), and [TIMESTAMP](#) values, with up to microseconds (6 digits) precision:

- To define a column that includes a fractional seconds part, use the syntax `type_name(fsp)`, where `type_name` is [TIME](#), [DATETIME](#), or [TIMESTAMP](#), and `fsp` is the fractional seconds precision. For example:

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0. (This differs from the standard SQL default of 6, for compatibility with previous MySQL versions.)

- Inserting a [TIME](#), [DATE](#), or [TIMESTAMP](#) value with a fractional seconds part into a column of the same type but having fewer fractional digits results in rounding. Consider a table created and populated as follows:

```
CREATE TABLE fractest( c1 TIME(2), c2 DATETIME(2), c3 TIMESTAMP(2) );
INSERT INTO fractest VALUES
('17:51:04.777', '2018-09-08 17:51:04.777', '2018-09-08 17:51:04.777');
```

The temporal values are inserted into the table with rounding:

```
mysql> SELECT * FROM fractest;
+-----+-----+-----+
| c1          | c2          | c3          |
+-----+-----+-----+
| 17:51:04.78 | 2018-09-08 17:51:04.78 | 2018-09-08 17:51:04.78 |
+-----+-----+-----+
```

No warning or error is given when such rounding occurs. This behavior follows the SQL standard.

To insert the values with truncation instead, enable the [TIME_TRUNCATE_FRACTIONAL](#) SQL mode:

```
SET @@sql_mode = sys.list_add(@@sql_mode, 'TIME_TRUNCATE_FRACTIONAL');
```

With that SQL mode enabled, the temporal values are inserted with truncation:

```
mysql> SELECT * FROM fractest;
+-----+-----+-----+
| c1          | c2          | c3          |
+-----+-----+-----+
| 17:51:04.77 | 2018-09-08 17:51:04.77 | 2018-09-08 17:51:04.77 |
+-----+-----+-----+
```

- Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate. For example, [NOW\(\)](#) with no argument returns the current date and time with no fractional part, but takes an optional argument from 0 to 6 to specify that the return value includes a fractional seconds part of that many digits.
- Syntax for temporal literals produces temporal values: [DATE 'str'](#), [TIME 'str'](#), and [TIMESTAMP 'str'](#), and the ODBC-syntax equivalents. The resulting value includes a trailing fractional seconds part if specified. Previously, the temporal type keyword was ignored and these constructs produced the string value. See [Standard SQL and ODBC Date and Time Literals](#)

11.2.7 Conversion Between Date and Time Types

To some extent, you can convert a value from one temporal type to another. However, there may be some alteration of the value or loss of information. In all cases, conversion between temporal types is subject to the range of valid values for the resulting type. For example, although [DATE](#), [DATETIME](#), and [TIMESTAMP](#) values all can be specified using the same set of formats, the types do not all have the same range of values. [TIMESTAMP](#) values cannot be earlier than 1970 UTC or later than

'2038-01-19 03:14:07' UTC. This means that a date such as '1968-01-01', while valid as a `DATE` or `DATETIME` value, is not valid as a `TIMESTAMP` value and is converted to 0.

Conversion of `DATE` values:

- Conversion to a `DATETIME` or `TIMESTAMP` value adds a time part of '00:00:00' because the `DATE` value contains no time information.
- Conversion to a `TIME` value is not useful; the result is '00:00:00'.

Conversion of `DATETIME` and `TIMESTAMP` values:

- Conversion to a `DATE` value takes fractional seconds into account and rounds the time part. For example, '1999-12-31 23:59:59.499' becomes '1999-12-31', whereas '1999-12-31 23:59:59.500' becomes '2000-01-01'.
- Conversion to a `TIME` value discards the date part because the `TIME` type contains no date information.

For conversion of `TIME` values to other temporal types, the value of `CURRENT_DATE()` is used for the date part. The `TIME` is interpreted as elapsed time (not time of day) and added to the date. This means that the date part of the result differs from the current date if the time value is outside the range from '00:00:00' to '23:59:59'.

Suppose that the current date is '2012-01-01'. `TIME` values of '12:00:00', '24:00:00', and '-12:00:00', when converted to `DATETIME` or `TIMESTAMP` values, result in '2012-01-01 12:00:00', '2012-01-02 00:00:00', and '2011-12-31 12:00:00', respectively.

Conversion of `TIME` to `DATE` is similar but discards the time part from the result: '2012-01-01', '2012-01-02', and '2011-12-31', respectively.

Explicit conversion can be used to override implicit conversion. For example, in comparison of `DATE` and `DATETIME` values, the `DATE` value is coerced to the `DATETIME` type by adding a time part of '00:00:00'. To perform the comparison by ignoring the time part of the `DATETIME` value instead, use the `CAST()` function in the following way:

```
date_col = CAST(datetime_col AS DATE)
```

Conversion of `TIME` and `DATETIME` values to numeric form (for example, by adding +0) depends on whether the value contains a fractional seconds part. `TIME(N)` or `DATETIME(N)` is converted to integer when `N` is 0 (or omitted) and to a `DECIMAL` value with `N` decimal digits when `N` is greater than 0:

```
mysql> SELECT CURTIME(), CURTIME()+0, CURTIME(3)+0;
+-----+-----+-----+
| CURTIME() | CURTIME()+0 | CURTIME(3)+0 |
+-----+-----+-----+
| 09:28:00 | 92800 | 92800.887 |
+-----+-----+-----+
mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+-----+-----+-----+
| NOW() | NOW()+0 | NOW(3)+0 |
+-----+-----+-----+
| 2012-08-15 09:28:00 | 20120815092800 | 20120815092800.889 |
+-----+-----+-----+
```

11.2.8 2-Digit Years in Dates

Date values with 2-digit years are ambiguous because the century is unknown. Such values must be interpreted into 4-digit form because MySQL stores years internally using 4 digits.

For `DATETIME`, `DATE`, and `TIMESTAMP` types, MySQL interprets dates specified with ambiguous year values using these rules:

- Year values in the range 00–69 become 2000–2069.
- Year values in the range 70–99 become 1970–1999.

For `YEAR`, the rules are the same, with this exception: A numeric `00` inserted into `YEAR` results in `0000` rather than `2000`. To specify zero for `YEAR` and have it be interpreted as `2000`, specify it as a string `'0'` or `'00'`.

Remember that these rules are only heuristics that provide reasonable guesses as to what your data values mean. If the rules used by MySQL do not produce the values you require, you must provide unambiguous input containing 4-digit year values.

`ORDER BY` properly sorts `YEAR` values that have 2-digit years.

Some functions like `MIN()` and `MAX()` convert a `YEAR` to a number. This means that a value with a 2-digit year does not work properly with these functions. The fix in this case is to convert the `YEAR` to 4-digit year format.

11.3 String Data Types

The string data types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`.

For information about storage requirements of the string data types, see [Section 11.7, “Data Type Storage Requirements”](#).

For descriptions of functions that operate on string values, see [Section 12.8, “String Functions and Operators”](#).

11.3.1 String Data Type Syntax

The string data types are `CHAR`, `VARCHAR`, `BINARY`, `VARBINARY`, `BLOB`, `TEXT`, `ENUM`, and `SET`.

In some cases, MySQL may change a string column to a type different from that given in a `CREATE TABLE` or `ALTER TABLE` statement. See [Section 13.1.20.7, “Silent Column Specification Changes”](#).

For definitions of character string columns (`CHAR`, `VARCHAR`, and the `TEXT` types), MySQL interprets length specifications in character units. For definitions of binary string columns (`BINARY`, `VARBINARY`, and the `BLOB` types), MySQL interprets length specifications in byte units.

Column definitions for character string data types `CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) can specify the column character set and collation:

- `CHARACTER SET` specifies the character set. If desired, a collation for the character set can be specified with the `COLLATE` attribute, along with any other attributes. For example:

```
CREATE TABLE t
(
  c1 VARCHAR(20) CHARACTER SET utf8,
  c2 TEXT CHARACTER SET latin1 COLLATE latin1_general_cs
);
```

This table definition creates a column named `c1` that has a character set of `utf8` with the default collation for that character set, and a column named `c2` that has a character set of `latin1` and a case-sensitive (`_cs`) collation.

The rules for assigning the character set and collation when either or both of `CHARACTER SET` and the `COLLATE` attribute are missing are described in [Section 10.3.5, “Column Character Set and Collation”](#).

`CHARSET` is a synonym for `CHARACTER SET`.

- Specifying the `CHARACTER SET binary` attribute for a character string data type causes the column to be created as the corresponding binary string data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
```

```
c1 VARCHAR(10) CHARACTER SET binary,
c2 TEXT CHARACTER SET binary,
c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

- The **BINARY** attribute is a nonstandard MySQL extension that is shorthand for specifying the binary (**_bin**) collation of the column character set (or of the table default character set if no column character set is specified). In this case, comparison and sorting are based on numeric character code values. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET latin1 BINARY,
  c2 TEXT BINARY
) CHARACTER SET utf8mb4;
```

The resulting table has this definition:

```
CREATE TABLE t (
  c1 VARCHAR(10) CHARACTER SET latin1 COLLATE latin1_bin,
  c2 TEXT CHARACTER SET utf8mb4 COLLATE utf8mb4_bin
) CHARACTER SET utf8mb4;
```

In MySQL 8.0, this nonstandard use of the **BINARY** attribute is ambiguous because the **utf8mb4** character set has multiple **_bin** collations. As of MySQL 8.0.17, the **BINARY** attribute is deprecated and support for it will be removed in a future MySQL version. Applications should be adjusted to use an explicit **_bin** collation instead.

The use of **BINARY** to specify a data type or character set remains unchanged.

- The **ASCII** attribute is shorthand for **CHARACTER SET latin1**.
- The **UNICODE** attribute is shorthand for **CHARACTER SET ucs2**.

Character column comparison and sorting are based on the collation assigned to the column. For the **CHAR**, **VARCHAR**, **TEXT**, **ENUM**, and **SET** data types, you can declare a column with a binary (**_bin**) collation or the **BINARY** attribute to cause comparison and sorting to use the underlying character code values rather than a lexical ordering.

For additional information about use of character sets in MySQL, see [Chapter 10, Character Sets, Collations, Unicode](#).

- **[NATIONAL] CHAR(*M*) [CHARACTER SET *charset_name*] [COLLATE *collation_name*]**

A fixed-length string that is always right-padded with spaces to the specified length when stored. *M* represents the column length in characters. The range of *M* is 0 to 255. If *M* is omitted, the length is 1.

Note

Trailing spaces are removed when **CHAR** values are retrieved unless the **PAD_CHAR_TO_FULL_LENGTH** SQL mode is enabled.

CHAR is shorthand for **CHARACTER**. **NATIONAL CHAR** (or its equivalent short form, **NCHAR**) is the standard SQL way to define that a **CHAR** column should use some predefined character set. MySQL uses **utf8** as this predefined character set. [Section 10.3.7, “The National Character Set”](#).

The `CHAR BYTE` data type is an alias for the `BINARY` data type. This is a compatibility feature.

MySQL permits you to create a column of type `CHAR(0)`. This is useful primarily when you must be compliant with old applications that depend on the existence of a column but that do not actually use its value. `CHAR(0)` is also quite nice when you need a column that can take only two values: A column that is defined as `CHAR(0) NULL` occupies only one bit and can take only the values `NULL` and `''` (the empty string).

- `[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]`

A variable-length string. *M* represents the maximum column length in characters. The range of *M* is 0 to 65,535. The effective maximum length of a `VARCHAR` is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. For example, `utf8` characters can require up to three bytes per character, so a `VARCHAR` column that uses the `utf8` character set can be declared to be a maximum of 21,844 characters. See [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

MySQL stores `VARCHAR` values as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A `VARCHAR` column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

Note

MySQL follows the standard SQL specification, and does *not* remove trailing spaces from `VARCHAR` values.

`VARCHAR` is shorthand for `CHARACTER VARYING`. `NATIONAL VARCHAR` is the standard SQL way to define that a `VARCHAR` column should use some predefined character set. MySQL uses `utf8` as this predefined character set. [Section 10.3.7, “The National Character Set”](#). `NVARCHAR` is shorthand for `NATIONAL VARCHAR`.

- `BINARY[(M)]`

The `BINARY` type is similar to the `CHAR` type, but stores binary byte strings rather than nonbinary character strings. An optional length *M* represents the column length in bytes. If omitted, *M* defaults to 1.

- `VARBINARY(M)`

The `VARBINARY` type is similar to the `VARCHAR` type, but stores binary byte strings rather than nonbinary character strings. *M* represents the maximum column length in bytes.

- `TINYBLOB`

A `BLOB` column with a maximum length of 255 ($2^8 - 1$) bytes. Each `TINYBLOB` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 255 ($2^8 - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each `TINYTEXT` value is stored using a 1-byte length prefix that indicates the number of bytes in the value.

- `BLOB[(M)]`

A `BLOB` column with a maximum length of 65,535 ($2^{16} - 1$) bytes. Each `BLOB` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length *M* can be given for this type. If this is done, MySQL creates the column as the smallest `BLOB` type large enough to hold values *M* bytes long.

- `TEXT[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 65,535 ($2^{16} - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each `TEXT` value is stored using a 2-byte length prefix that indicates the number of bytes in the value.

An optional length *M* can be given for this type. If this is done, MySQL creates the column as the smallest `TEXT` type large enough to hold values *M* characters long.

- `MEDIUMBLOB`

A `BLOB` column with a maximum length of 16,777,215 ($2^{24} - 1$) bytes. Each `MEDIUMBLOB` value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- `MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 16,777,215 ($2^{24} - 1$) characters. The effective maximum length is less if the value contains multibyte characters. Each `MEDIUMTEXT` value is stored using a 3-byte length prefix that indicates the number of bytes in the value.

- `LONGBLOB`

A `BLOB` column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) bytes. The effective maximum length of `LONGBLOB` columns depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGBLOB` value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- `LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]`

A `TEXT` column with a maximum length of 4,294,967,295 or 4GB ($2^{32} - 1$) characters. The effective maximum length is less if the value contains multibyte characters. The effective maximum length of `LONGTEXT` columns also depends on the configured maximum packet size in the client/server protocol and available memory. Each `LONGTEXT` value is stored using a 4-byte length prefix that indicates the number of bytes in the value.

- `ENUM('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]`

An enumeration. A string object that can have only one value, chosen from the list of values 'value1', 'value2', ..., `NULL` or the special '' error value. `ENUM` values are represented internally as integers.

An `ENUM` column can have a maximum of 65,535 distinct elements.

The maximum supported length of an individual `ENUM` element is $M \leq 255$ and $(M \times w) \leq 1020$, where *M* is the element literal length and *w* is the number of bytes required for the maximum-length character in the character set.

- `SET('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]`

A set. A string object that can have zero or more values, each of which must be chosen from the list of values 'value1', 'value2', ... `SET` values are represented internally as integers.

A `SET` column can have a maximum of 64 distinct members.

The maximum supported length of an individual `SET` element is $M \leq 255$ and $(M \times w) \leq 1020$, where *M* is the element literal length and *w* is the number of bytes required for the maximum-length character in the character set.

11.3.2 The CHAR and VARCHAR Types

The [CHAR](#) and [VARCHAR](#) types are similar, but differ in the way they are stored and retrieved. They also differ in maximum length and in whether trailing spaces are retained.

The [CHAR](#) and [VARCHAR](#) types are declared with a length that indicates the maximum number of characters you want to store. For example, [CHAR\(30\)](#) can hold up to 30 characters.

The length of a [CHAR](#) column is fixed to the length that you declare when you create the table. The length can be any value from 0 to 255. When [CHAR](#) values are stored, they are right-padded with spaces to the specified length. When [CHAR](#) values are retrieved, trailing spaces are removed unless the [PAD_CHAR_TO_FULL_LENGTH](#) SQL mode is enabled.

Values in [VARCHAR](#) columns are variable-length strings. The length can be specified as a value from 0 to 65,535. The effective maximum length of a [VARCHAR](#) is subject to the maximum row size (65,535 bytes, which is shared among all columns) and the character set used. See [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

In contrast to [CHAR](#), [VARCHAR](#) values are stored as a 1-byte or 2-byte length prefix plus data. The length prefix indicates the number of bytes in the value. A column uses one length byte if values require no more than 255 bytes, two length bytes if values may require more than 255 bytes.

If strict SQL mode is not enabled and you assign a value to a [CHAR](#) or [VARCHAR](#) column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.11, “Server SQL Modes”](#).

For [VARCHAR](#) columns, trailing spaces in excess of the column length are truncated prior to insertion and a warning is generated, regardless of the SQL mode in use. For [CHAR](#) columns, truncation of excess trailing spaces from inserted values is performed silently regardless of the SQL mode.

[VARCHAR](#) values are not padded when they are stored. Trailing spaces are retained when values are stored and retrieved, in conformance with standard SQL.

The following table illustrates the differences between [CHAR](#) and [VARCHAR](#) by showing the result of storing various string values into [CHAR\(4\)](#) and [VARCHAR\(4\)](#) columns (assuming that the column uses a single-byte character set such as [latin1](#)).

Value	CHAR(4)	Storage Required	VARCHAR(4)	Storage Required
' '	' '	4 bytes	' '	1 byte
'ab'	'ab '	4 bytes	'ab'	3 bytes
'abcd'	'abcd'	4 bytes	'abcd'	5 bytes
'abcdefgh'	'abcd'	4 bytes	'abcd'	5 bytes

The values shown as stored in the last row of the table apply *only when not using strict SQL mode*; if strict mode is enabled, values that exceed the column length are *not stored*, and an error results.

[InnoDB](#) encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a [CHAR\(255\)](#) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with [utf8mb4](#).

If a given value is stored into the [CHAR\(4\)](#) and [VARCHAR\(4\)](#) columns, the values retrieved from the columns are not always the same because trailing spaces are removed from [CHAR](#) columns upon retrieval. The following example illustrates this difference:

```
mysql> CREATE TABLE vc (v VARCHAR(4), c CHAR(4));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO vc VALUES ('ab ', 'ab ');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT CONCAT('(', v, ')'), CONCAT('(', c, ')') FROM vc;
+-----+-----+
| CONCAT('(', v, ')') | CONCAT('(', c, ')') |
+-----+-----+
| (ab )              | (ab)                |
+-----+-----+
1 row in set (0.06 sec)
```

Values in [CHAR](#), [VARCHAR](#), and [TEXT](#) columns are sorted and compared according to the character set collation assigned to the column.

MySQL collations have a pad attribute of [PAD SPACE](#), other than Unicode collations based on UCA 9.0.0 and higher, which have a pad attribute of [NO PAD](#). (see [Section 10.10.1, “Unicode Character Sets”](#)).

To determine the pad attribute for a collation, use the [INFORMATION_SCHEMA COLLATIONS](#) table, which has a [PAD_ATTRIBUTE](#) column.

For nonbinary strings ([CHAR](#), [VARCHAR](#), and [TEXT](#) values), the string collation pad attribute determines treatment in comparisons of trailing spaces at the end of strings. [NO PAD](#) collations treat trailing spaces as significant in comparisons, like any other character. [PAD SPACE](#) collations treat trailing spaces as insignificant in comparisons; strings are compared without regard to trailing spaces. See [Trailing Space Handling in Comparisons](#). The server SQL mode has no effect on comparison behavior with respect to trailing spaces.

Note

For more information about MySQL character sets and collations, see [Chapter 10, Character Sets, Collations, Unicode](#). For additional information about storage requirements, see [Section 11.7, “Data Type Storage Requirements”](#).

For those cases where trailing pad characters are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting into the column values that differ only in number of trailing pad characters results in a duplicate-key error. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error.

11.3.3 The BINARY and VARBINARY Types

The [BINARY](#) and [VARBINARY](#) types are similar to [CHAR](#) and [VARCHAR](#), except that they store binary strings rather than nonbinary strings. That is, they store byte strings rather than character strings. This means they have the [binary](#) character set and collation, and comparison and sorting are based on the numeric values of the bytes in the values.

The permissible maximum length is the same for [BINARY](#) and [VARBINARY](#) as it is for [CHAR](#) and [VARCHAR](#), except that the length for [BINARY](#) and [VARBINARY](#) is measured in bytes rather than characters.

The [BINARY](#) and [VARBINARY](#) data types are distinct from the [CHAR BINARY](#) and [VARCHAR BINARY](#) data types. For the latter types, the [BINARY](#) attribute does not cause the column to be treated as a binary string column. Instead, it causes the binary ([_bin](#)) collation for the column character set (or the table default character set if no column character set is specified) to be used, and the column itself stores nonbinary character strings rather than binary byte strings. For example, if the default character set is [utf8mb4](#), [CHAR\(5\) BINARY](#) is treated as [CHAR\(5\) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin](#). This differs from [BINARY\(5\)](#), which stores 5-byte binary strings that have the [binary](#) character set and collation. For information about the differences between the [binary](#) collation of the [binary](#) character set and the [_bin](#) collations of nonbinary character sets, see [Section 10.8.5, “The binary Collation Compared to _bin Collations”](#).

If strict SQL mode is not enabled and you assign a value to a [BINARY](#) or [VARBINARY](#) column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For

cases of truncation, to cause an error to occur (rather than a warning) and suppress insertion of the value, use strict SQL mode. See [Section 5.1.11, “Server SQL Modes”](#).

When `BINARY` values are stored, they are right-padded with the pad value to the specified length. The pad value is `0x00` (the zero byte). Values are right-padded with `0x00` for inserts, and no trailing bytes are removed for retrievals. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` and space differ in comparisons, with `0x00` sorting before space.

Example: For a `BINARY(3)` column, `'a '` becomes `'a \0'` when inserted. `'a\0'` becomes `'a \0\0'` when inserted. Both inserted values remain unchanged for retrievals.

For `VARBINARY`, there is no padding for inserts and no bytes are stripped for retrievals. All bytes are significant in comparisons, including `ORDER BY` and `DISTINCT` operations. `0x00` and space differ in comparisons, with `0x00` sorting before space.

For those cases where trailing pad bytes are stripped or comparisons ignore them, if a column has an index that requires unique values, inserting values into the column that differ only in number of trailing pad bytes results in a duplicate-key error. For example, if a table contains `'a '`, an attempt to store `'a \0'` causes a duplicate-key error.

You should consider the preceding padding and stripping characteristics carefully if you plan to use the `BINARY` data type for storing binary data and you require that the value retrieved be exactly the same as the value stored. The following example illustrates how `0x00`-padding of `BINARY` values affects column value comparisons:

```
mysql> CREATE TABLE t (c BINARY(3));
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET c = 'a';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT HEX(c), c = 'a', c = 'a\0\0' from t;
+-----+-----+-----+
| HEX(c) | c = 'a' | c = 'a\0\0' |
+-----+-----+-----+
| 610000 |      0 |           1 |
+-----+-----+-----+
1 row in set (0.09 sec)
```

If the value retrieved must be the same as the value specified for storage with no padding, it might be preferable to use `VARBINARY` or one of the `BLOB` data types instead.

11.3.4 The BLOB and TEXT Types

A `BLOB` is a binary large object that can hold a variable amount of data. The four `BLOB` types are `TINYBLOB`, `BLOB`, `MEDIUMBLOB`, and `LONGBLOB`. These differ only in the maximum length of the values they can hold. The four `TEXT` types are `TINYTEXT`, `TEXT`, `MEDIUMTEXT`, and `LONGTEXT`. These correspond to the four `BLOB` types and have the same maximum lengths and storage requirements. See [Section 11.7, “Data Type Storage Requirements”](#).

`BLOB` values are treated as binary strings (byte strings). They have the `binary` character set and collation, and comparison and sorting are based on the numeric values of the bytes in column values. `TEXT` values are treated as nonbinary strings (character strings). They have a character set other than `binary`, and values are sorted and compared based on the collation of the character set.

If strict SQL mode is not enabled and you assign a value to a `BLOB` or `TEXT` column that exceeds the column's maximum length, the value is truncated to fit and a warning is generated. For truncation of nonspace characters, you can cause an error to occur (rather than a warning) and suppress insertion of the value by using strict SQL mode. See [Section 5.1.11, “Server SQL Modes”](#).

Truncation of excess trailing spaces from values to be inserted into `TEXT` columns always generates a warning, regardless of the SQL mode.

For `TEXT` and `BLOB` columns, there is no padding on insert and no bytes are stripped on select.

If a `TEXT` column is indexed, index entry comparisons are space-padded at the end. This means that, if the index requires unique values, duplicate-key errors will occur for values that differ only in the number of trailing spaces. For example, if a table contains 'a', an attempt to store 'a ' causes a duplicate-key error. This is not true for `BLOB` columns.

In most respects, you can regard a `BLOB` column as a `VARBINARY` column that can be as large as you like. Similarly, you can regard a `TEXT` column as a `VARCHAR` column. `BLOB` and `TEXT` differ from `VARBINARY` and `VARCHAR` in the following ways:

- For indexes on `BLOB` and `TEXT` columns, you must specify an index prefix length. For `CHAR` and `VARCHAR`, a prefix length is optional. See [Section 8.3.5, “Column Indexes”](#).
- `BLOB` and `TEXT` columns cannot have `DEFAULT` values.

If you use the `BINARY` attribute with a `TEXT` data type, the column is assigned the binary (`_bin`) collation of the column character set.

`LONG` and `LONG VARCHAR` map to the `MEDIUMTEXT` data type. This is a compatibility feature.

MySQL Connector/ODBC defines `BLOB` values as `LONGVARBINARY` and `TEXT` values as `LONGVARCHAR`.

Because `BLOB` and `TEXT` values can be extremely long, you might encounter some constraints in using them:

- Only the first `max_sort_length` bytes of the column are used when sorting. The default value of `max_sort_length` is 1024. You can make more bytes significant in sorting or grouping by increasing the value of `max_sort_length` at server startup or runtime. Any client can change the value of its session `max_sort_length` variable:

```
mysql> SET max_sort_length = 2000;
mysql> SELECT id, comment FROM t
       -> ORDER BY comment;
```

- Instances of `BLOB` or `TEXT` columns in the result of a query that is processed using a temporary table causes the server to use a table on disk rather than in memory because the `MEMORY` storage engine does not support those data types (see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#)). Use of disk incurs a performance penalty, so include `BLOB` or `TEXT` columns in the query result only if they are really needed. For example, avoid using `SELECT *`, which selects all columns.
- The maximum size of a `BLOB` or `TEXT` object is determined by its type, but the largest value you actually can transmit between the client and server is determined by the amount of available memory and the size of the communications buffers. You can change the message buffer size by changing the value of the `max_allowed_packet` variable, but you must do so for both the server and your client program. For example, both `mysql` and `mysqldump` enable you to change the client-side `max_allowed_packet` value. See [Section 5.1.1, “Configuring the Server”](#), [Section 4.5.1, “mysql — The MySQL Command-Line Client”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). You may also want to compare the packet sizes and the size of the data objects you are storing with the storage requirements, see [Section 11.7, “Data Type Storage Requirements”](#)

Each `BLOB` or `TEXT` value is represented internally by a separately allocated object. This is in contrast to all other data types, for which storage is allocated once per column when the table is opened.

In some cases, it may be desirable to store binary data such as media files in `BLOB` or `TEXT` columns. You may find MySQL's string handling functions useful for working with such data. See [Section 12.8, “String Functions and Operators”](#). For security and other reasons, it is usually preferable to do so using application code rather than giving application users the `FILE` privilege. You can discuss specifics for various languages and platforms in the MySQL Forums (<http://forums.mysql.com/>).

11.3.5 The ENUM Type

An [ENUM](#) is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification at table creation time.

See [Section 11.3.1, “String Data Type Syntax”](#) for [ENUM](#) type syntax and length limits.

The [ENUM](#) type has these advantages:

- Compact data storage in situations where a column has a limited set of possible values. The strings you specify as input values are automatically encoded as numbers. See [Section 11.7, “Data Type Storage Requirements”](#) for storage requirements for the [ENUM](#) type.
- Readable queries and output. The numbers are translated back to the corresponding strings in query results.

and these potential issues to consider:

- If you make enumeration values that look like numbers, it is easy to mix up the literal values with their internal index numbers, as explained in [Enumeration Limitations](#).
- Using [ENUM](#) columns in [ORDER BY](#) clauses requires extra care, as explained in [Enumeration Sorting](#).
- [Creating and Using ENUM Columns](#)
- [Index Values for Enumeration Literals](#)
- [Handling of Enumeration Literals](#)
- [Empty or NULL Enumeration Values](#)
- [Enumeration Sorting](#)
- [Enumeration Limitations](#)

Creating and Using ENUM Columns

An enumeration value must be a quoted string literal. For example, you can create a table with an [ENUM](#) column like this:

```
CREATE TABLE shirts (
  name VARCHAR(40),
  size ENUM('x-small', 'small', 'medium', 'large', 'x-large')
);
INSERT INTO shirts (name, size) VALUES ('dress shirt','large'), ('t-shirt','medium'),
('polo shirt','small');
SELECT name, size FROM shirts WHERE size = 'medium';
+-----+-----+
| name   | size   |
+-----+-----+
| t-shirt | medium |
+-----+-----+
UPDATE shirts SET size = 'small' WHERE size = 'large';
COMMIT;
```

Inserting 1 million rows into this table with a value of ['medium'](#) would require 1 million bytes of storage, as opposed to 6 million bytes if you stored the actual string ['medium'](#) in a [VARCHAR](#) column.

Index Values for Enumeration Literals

Each enumeration value has an index:

- The elements listed in the column specification are assigned index numbers, beginning with 1.
- The index value of the empty string error value is 0. This means that you can use the following [SELECT](#) statement to find rows into which invalid [ENUM](#) values were assigned:

```
mysql> SELECT * FROM tbl_name WHERE enum_col=0;
```

- The index of the `NULL` value is `NULL`.
- The term “index” here refers to a position within the list of enumeration values. It has nothing to do with table indexes.

For example, a column specified as `ENUM('Mercury', 'Venus', 'Earth')` can have any of the values shown here. The index of each value is also shown.

Value	Index
<code>NULL</code>	<code>NULL</code>
<code>' '</code>	0
<code>'Mercury'</code>	1
<code>'Venus'</code>	2
<code>'Earth'</code>	3

An `ENUM` column can have a maximum of 65,535 distinct elements.

If you retrieve an `ENUM` value in a numeric context, the column value's index is returned. For example, you can retrieve numeric values from an `ENUM` column like this:

```
mysql> SELECT enum_col+0 FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `ENUM` values, the index number is used in the calculation.

Handling of Enumeration Literals

Trailing spaces are automatically deleted from `ENUM` member values in the table definition when a table is created.

When retrieved, values stored into an `ENUM` column are displayed using the lettercase that was used in the column definition. Note that `ENUM` columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

If you store a number into an `ENUM` column, the number is treated as the index into the possible values, and the value stored is the enumeration member with that index. (However, this does *not* work with `LOAD DATA`, which treats all input as strings.) If the numeric value is quoted, it is still interpreted as an index if there is no matching string in the list of enumeration values. For these reasons, it is not advisable to define an `ENUM` column with enumeration values that look like numbers, because this can easily become confusing. For example, the following column has enumeration members with string values of `'0'`, `'1'`, and `'2'`, but numeric index values of 1, 2, and 3:

```
numbers ENUM('0','1','2')
```

If you store 2, it is interpreted as an index value, and becomes `'1'` (the value with index 2). If you store `'2'`, it matches an enumeration value, so it is stored as `'2'`. If you store `'3'`, it does not match any enumeration value, so it is treated as an index and becomes `'2'` (the value with index 3).

```
mysql> INSERT INTO t (numbers) VALUES(2),('2'),('3');
mysql> SELECT * FROM t;
+-----+
| numbers |
+-----+
| 1       |
| 2       |
| 2       |
```

```
+-----+
```

To determine all possible values for an `ENUM` column, use `SHOW COLUMNS FROM tbl_name LIKE 'enum_col'` and parse the `ENUM` definition in the `Type` column of the output.

In the C API, `ENUM` values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [C API Data Structures](#).

Empty or NULL Enumeration Values

An enumeration value can also be the empty string (`' '`) or `NULL` under certain circumstances:

- If you insert an invalid value into an `ENUM` (that is, a string not present in the list of permitted values), the empty string is inserted instead as a special error value. This string can be distinguished from a “normal” empty string by the fact that this string has the numeric value 0. See [Index Values for Enumeration Literals](#) for details about the numeric indexes for the enumeration values.

If strict SQL mode is enabled, attempts to insert invalid `ENUM` values result in an error.

- If an `ENUM` column is declared to permit `NULL`, the `NULL` value is a valid value for the column, and the default value is `NULL`. If an `ENUM` column is declared `NOT NULL`, its default value is the first element of the list of permitted values.

Enumeration Sorting

`ENUM` values are sorted based on their index numbers, which depend on the order in which the enumeration members were listed in the column specification. For example, `'b'` sorts before `'a'` for `ENUM('b', 'a')`. The empty string sorts before nonempty strings, and `NULL` values sort before all other enumeration values.

To prevent unexpected results when using the `ORDER BY` clause on an `ENUM` column, use one of these techniques:

- Specify the `ENUM` list in alphabetic order.
- Make sure that the column is sorted lexically rather than by index number by coding `ORDER BY CAST(col AS CHAR)` or `ORDER BY CONCAT(col)`.

Enumeration Limitations

An enumeration value cannot be an expression, even one that evaluates to a string value.

For example, this `CREATE TABLE` statement does *not* work because the `CONCAT` function cannot be used to construct an enumeration value:

```
CREATE TABLE sizes (  
    size ENUM('small', CONCAT('med','ium'), 'large')  
);
```

You also cannot employ a user variable as an enumeration value. This pair of statements do *not* work:

```
SET @mysize = 'medium';  
  
CREATE TABLE sizes (  
    size ENUM('small', @mysize, 'large')  
);
```

We strongly recommend that you do *not* use numbers as enumeration values, because it does not save on storage over the appropriate `TINYINT` or `SMALLINT` type, and it is easy to mix up the strings and the underlying number values (which might not be the same) if you quote the `ENUM` values incorrectly. If you do use a number as an enumeration value, always enclose it in quotation marks. If the quotation marks are omitted, the number is regarded as an index. See [Handling of Enumeration Literals](#) to see how even a quoted number could be mistakenly used as a numeric index value.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

11.3.6 The SET Type

A **SET** is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. **SET** column values that consist of multiple set members are specified with members separated by commas (,). A consequence of this is that **SET** member values should not themselves contain commas.

For example, a column specified as **SET('one', 'two') NOT NULL** can have any of these values:

```
' '
'one'
'two'
'one,two'
```

A **SET** column can have a maximum of 64 distinct members.

Duplicate values in the definition cause a warning, or an error if strict SQL mode is enabled.

Trailing spaces are automatically deleted from **SET** member values in the table definition when a table is created.

See [String Type Storage Requirements](#) for storage requirements for the **SET** type.

See [Section 11.3.1, “String Data Type Syntax”](#) for **SET** type syntax and length limits.

When retrieved, values stored in a **SET** column are displayed using the lettercase that was used in the column definition. Note that **SET** columns can be assigned a character set and collation. For binary or case-sensitive collations, lettercase is taken into account when assigning values to the column.

MySQL stores **SET** values numerically, with the low-order bit of the stored value corresponding to the first set member. If you retrieve a **SET** value in a numeric context, the value retrieved has bits set corresponding to the set members that make up the column value. For example, you can retrieve numeric values from a **SET** column like this:

```
mysql> SELECT set_col+0 FROM tbl_name;
```

If a number is stored into a **SET** column, the bits that are set in the binary representation of the number determine the set members in the column value. For a column specified as **SET('a', 'b', 'c', 'd')**, the members have the following decimal and binary values.

SET Member	Decimal Value	Binary Value
'a'	1	0001
'b'	2	0010
'c'	4	0100
'd'	8	1000

If you assign a value of 9 to this column, that is 1001 in binary, so the first and fourth **SET** value members 'a' and 'd' are selected and the resulting value is 'a,d'.

For a value containing more than one **SET** element, it does not matter what order the elements are listed in when you insert the value. It also does not matter how many times a given element is listed in the value. When the value is retrieved later, each element in the value appears once, with elements listed according to the order in which they were specified at table creation time. Suppose that a column is specified as **SET('a', 'b', 'c', 'd')**:

```
mysql> CREATE TABLE myset (col SET('a', 'b', 'c', 'd'));
```

If you insert the values 'a,d', 'd,a', 'a,d,d', 'a,d,a', and 'd,a,d':

```
mysql> INSERT INTO myset (col) VALUES
-> ('a,d'), ('d,a'), ('a,d,a'), ('a,d,d'), ('d,a,d');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

Then all these values appear as 'a,d' when retrieved:

```
mysql> SELECT col FROM myset;
+-----+
| col   |
+-----+
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
+-----+
5 rows in set (0.04 sec)
```

If you set a **SET** column to an unsupported value, the value is ignored and a warning is issued:

```
mysql> INSERT INTO myset (col) VALUES ('a,d,d,s');
Query OK, 1 row affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'col' at row 1 |
+-----+-----+-----+
1 row in set (0.04 sec)

mysql> SELECT col FROM myset;
+-----+
| col   |
+-----+
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
| a,d   |
+-----+
6 rows in set (0.01 sec)
```

If strict SQL mode is enabled, attempts to insert invalid **SET** values result in an error.

SET values are sorted numerically. **NULL** values sort before non-**NULL** **SET** values.

Functions such as **SUM()** or **AVG()** that expect a numeric argument cast the argument to a number if necessary. For **SET** values, the cast operation causes the numeric value to be used.

Normally, you search for **SET** values using the **FIND_IN_SET()** function or the **LIKE** operator:

```
mysql> SELECT * FROM tbl_name WHERE FIND_IN_SET('value',set_col)>0;
mysql> SELECT * FROM tbl_name WHERE set_col LIKE '%value%';
```

The first statement finds rows where *set_col* contains the *value* set member. The second is similar, but not the same: It finds rows where *set_col* contains *value* anywhere, even as a substring of another set member.

The following statements also are permitted:

```
mysql> SELECT * FROM tbl_name WHERE set_col & 1;
mysql> SELECT * FROM tbl_name WHERE set_col = 'val1,val2';
```

The first of these statements looks for values containing the first set member. The second looks for an exact match. Be careful with comparisons of the second type. Comparing set values to 'val1,val2'

returns different results than comparing values to `'val2,val1'`. You should specify the values in the same order they are listed in the column definition.

To determine all possible values for a `SET` column, use `SHOW COLUMNS FROM tbl_name LIKE set_col` and parse the `SET` definition in the `Type` column of the output.

In the C API, `SET` values are returned as strings. For information about using result set metadata to distinguish them from other strings, see [C API Data Structures](#).

11.4 Spatial Data Types

The [Open Geospatial Consortium](#) (OGC) is an international consortium of more than 250 companies, agencies, and universities participating in the development of publicly available conceptual solutions that can be useful with all kinds of applications that manage spatial data.

The Open Geospatial Consortium publishes the *OpenGIS® Implementation Standard for Geographic information - Simple feature access - Part 2: SQL option*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. This specification is available from the OGC website at <http://www.opengeospatial.org/standards/sfs>.

Following the OGC specification, MySQL implements spatial extensions as a subset of the **SQL with Geometry Types** environment. This term refers to an SQL environment that has been extended with a set of geometry types. A geometry-valued SQL column is implemented as a column that has a geometry type. The specification describes a set of SQL geometry types, as well as functions on those types to create and analyze geometry values.

MySQL spatial extensions enable the generation, storage, and analysis of geographic features:

- Data types for representing spatial values
- Functions for manipulating spatial values
- Spatial indexing for improved access times to spatial columns

The spatial data types and functions are available for [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) tables. For indexing spatial columns, [MyISAM](#) and [InnoDB](#) support both `SPATIAL` and non-`SPATIAL` indexes. The other storage engines support non-`SPATIAL` indexes, as described in [Section 13.1.15, “CREATE INDEX Statement”](#).

A **geographic feature** is anything in the world that has a location. A feature can be:

- An entity. For example, a mountain, a pond, a city.
- A space. For example, town district, the tropics.
- A definable location. For example, a crossroad, as a particular place where two streets intersect.

Some documents use the term **geospatial feature** to refer to geographic features.

Geometry is another word that denotes a geographic feature. Originally the word **geometry** meant measurement of the earth. Another meaning comes from cartography, referring to the geometric features that cartographers use to map the world.

The discussion here considers these terms synonymous: **geographic feature**, **geospatial feature**, **feature**, or **geometry**. The term most commonly used is **geometry**, defined as *a point or an aggregate of points representing anything in the world that has a location*.

The following material covers these topics:

- The spatial data types implemented in MySQL model

- The basis of the spatial extensions in the OpenGIS geometry model
- Data formats for representing spatial data
- How to use spatial data in MySQL
- Use of indexing for spatial data
- MySQL differences from the OpenGIS specification

For information about functions that operate on spatial data, see [Section 12.17](#), “Spatial Analysis Functions”.

Additional Resources

These standards are important for the MySQL implementation of spatial operations:

- SQL/MM Part 3: Spatial.
- The [Open Geospatial Consortium](#) publishes the *OpenGIS® Implementation Standard for Geographic information*, a document that proposes several conceptual ways for extending an SQL RDBMS to support spatial data. See in particular Simple Feature Access - Part 1: Common Architecture, and Simple Feature Access - Part 2: SQL Option. The Open Geospatial Consortium (OGC) maintains a website at <http://www.opengeospatial.org/>. The specification is available there at <http://www.opengeospatial.org/standards/sfs>. It contains additional information relevant to the material here.
- The grammar for [spatial reference system](#) (SRS) definitions is based on the grammar defined in *OpenGIS Implementation Specification: Coordinate Transformation Services*, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at <http://www.opengeospatial.org/standards/ct>. For differences from that specification in SRS definitions as implemented in MySQL, see [Section 13.1.19](#), “CREATE SPATIAL REFERENCE SYSTEM Statement”.

If you have questions or concerns about the use of the spatial extensions to MySQL, you can discuss them in the GIS forum: <https://forums.mysql.com/list.php?23>.

11.4.1 Spatial Data Types

MySQL has spatial data types that correspond to OpenGIS classes. The basis for these types is described in [Section 11.4.2](#), “The OpenGIS Geometry Model”.

Some spatial data types hold single geometry values:

- [GEOMETRY](#)
- [POINT](#)
- [LINESTRING](#)
- [POLYGON](#)

[GEOMETRY](#) can store geometry values of any type. The other single-value types ([POINT](#), [LINESTRING](#), and [POLYGON](#)) restrict their values to a particular geometry type.

The other spatial data types hold collections of values:

- [MULTIPOINT](#)
- [MULTILINESTRING](#)
- [MULTIPOLYGON](#)

- [GEOMETRYCOLLECTION](#)

[GEOMETRYCOLLECTION](#) can store a collection of objects of any type. The other collection types ([MULTIPOINT](#), [MULTILINESTRING](#), and [MULTIPOLYGON](#)) restrict collection members to those having a particular geometry type.

Example: To create a table named [geom](#) that has a column named [g](#) that can store values of any geometry type, use this statement:

```
CREATE TABLE geom (g GEOMETRY);
```

Columns with a spatial data type can have an [SRID](#) attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For example:

```
CREATE TABLE geom (  
  p POINT SRID 0,  
  g GEOMETRY NOT NULL SRID 4326  
);
```

[SPATIAL](#) indexes can be created on spatial columns if they are [NOT NULL](#) and have a specific SRID, so if you plan to index the column, declare it with the [NOT NULL](#) and [SRID](#) attributes:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
```

[InnoDB](#) tables permit [SRID](#) values for Cartesian and geographic SRSs. [MyISAM](#) tables permit [SRID](#) values for Cartesian SRSs.

The [SRID](#) attribute makes a spatial column SRID-restricted, which has these implications:

- The column can contain only values with the given SRID. Attempts to insert values with a different SRID produce an error.
- The optimizer can use [SPATIAL](#) indexes on the column. See [Section 8.3.3, “SPATIAL Index Optimization”](#).

Spatial columns with no [SRID](#) attribute are not SRID-restricted and accept values with any SRID. However, the optimizer cannot use [SPATIAL](#) indexes on them until the column definition is modified to include an [SRID](#) attribute, which may require that the column contents first be modified so that all values have the same SRID.

For other examples showing how to use spatial data types in MySQL, see [Section 11.4.6, “Creating Spatial Columns”](#). For information about spatial reference systems, see [Section 11.4.5, “Spatial Reference System Support”](#).

11.4.2 The OpenGIS Geometry Model

The set of geometry types proposed by OGC's **SQL with Geometry Types** environment is based on the **OpenGIS Geometry Model**. In this model, each geometric object has the following general properties:

- It is associated with a spatial reference system, which describes the coordinate space in which the object is defined.
- It belongs to some geometry class.

11.4.2.1 The Geometry Class Hierarchy

The geometry classes define a hierarchy as follows:

- [Geometry](#) (noninstantiable)
 - [Point](#) (instantiable)

- `Curve` (noninstantiable)
 - `LineString` (instantiable)
 - `Line`
 - `LinearRing`
- `Surface` (noninstantiable)
 - `Polygon` (instantiable)
- `GeometryCollection` (instantiable)
 - `MultiPoint` (instantiable)
 - `MultiCurve` (noninstantiable)
 - `MultiLineString` (instantiable)
 - `MultiSurface` (noninstantiable)
 - `MultiPolygon` (instantiable)

It is not possible to create objects in noninstantiable classes. It is possible to create objects in instantiable classes. All classes have properties, and instantiable classes may also have assertions (rules that define valid class instances).

`Geometry` is the base class. It is an abstract class. The instantiable subclasses of `Geometry` are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base `Geometry` class has subclasses for `Point`, `Curve`, `Surface`, and `GeometryCollection`:

- `Point` represents zero-dimensional objects.
- `Curve` represents one-dimensional objects, and has subclass `LineString`, with sub-subclasses `Line` and `LinearRing`.
- `Surface` is designed for two-dimensional objects and has subclass `Polygon`.
- `GeometryCollection` has specialized zero-, one-, and two-dimensional collection classes named `MultiPoint`, `MultiLineString`, and `MultiPolygon` for modeling geometries corresponding to collections of `Points`, `LineStrings`, and `Polygons`, respectively. `MultiCurve` and `MultiSurface` are introduced as abstract superclasses that generalize the collection interfaces to handle `Curves` and `Surfaces`.

`Geometry`, `Curve`, `Surface`, `MultiCurve`, and `MultiSurface` are defined as noninstantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

`Point`, `LineString`, `Polygon`, `GeometryCollection`, `MultiPoint`, `MultiLineString`, and `MultiPolygon` are instantiable classes.

11.4.2.2 Geometry Class

`Geometry` is the root class of the hierarchy. It is a noninstantiable class but has a number of properties, described in the following list, that are common to all geometry values created from any of the `Geometry` subclasses. Particular subclasses have their own specific properties, described later.

Geometry Properties

A geometry value has the following properties:

- Its **type**. Each geometry belongs to one of the instantiable classes in the hierarchy.
- Its **SRID**, or spatial reference identifier. This value identifies the geometry's associated spatial reference system that describes the coordinate space in which the geometry object is defined.

In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32}-1$. If a larger value is given, only the lower 32 bits are used.

SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

For computations on multiple geometry values, all values must have the same SRID or an error occurs.

- Its **coordinates** in its spatial reference system, represented as double-precision (8-byte) numbers. All nonempty geometries include at least one pair of (X,Y) coordinates. Empty geometries contain no coordinates.

Coordinates are related to the SRID. For example, in different coordinate systems, the distance between two objects may differ even when objects have the same coordinates, because the distance on the **planar** coordinate system and the distance on the **geodetic** system (coordinates on the Earth's surface) are different things.

- Its **interior**, **boundary**, and **exterior**.

Every geometry occupies some position in space. The exterior of a geometry is all space not occupied by the geometry. The interior is the space occupied by the geometry. The boundary is the interface between the geometry's interior and exterior.

- Its **MBR** (minimum bounding rectangle), or envelope. This is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

- Whether the value is **simple** or **nonsimple**. Geometry values of types ([LineString](#), [MultiPoint](#), [MultiLineString](#)) are either simple or nonsimple. Each type determines its own assertions for being simple or nonsimple.
- Whether the value is **closed** or **not closed**. Geometry values of types ([LineString](#), [MultiString](#)) are either closed or not closed. Each type determines its own assertions for being closed or not closed.
- Whether the value is **empty** or **nonempty**. A geometry is empty if it does not have any points. Exterior, interior, and boundary of an empty geometry are not defined (that is, they are represented by a [NULL](#) value). An empty geometry is defined to be always simple and has an area of 0.
- Its **dimension**. A geometry can have a dimension of -1, 0, 1, or 2:
 - -1 for an empty geometry.
 - 0 for a geometry with no length and no area.
 - 1 for a geometry with nonzero length and zero area.
 - 2 for a geometry with nonzero area.

[Point](#) objects have a dimension of zero. [LineString](#) objects have a dimension of 1. [Polygon](#) objects have a dimension of 2. The dimensions of [MultiPoint](#), [MultiLineString](#), and [MultiPolygon](#) objects are the same as the dimensions of the elements they consist of.

11.4.2.3 Point Class

A [Point](#) is a geometry that represents a single location in coordinate space.

[Point](#) Examples

- Imagine a large-scale map of the world with many cities. A [Point](#) object could represent each city.
- On a city map, a [Point](#) object could represent a bus stop.

[Point](#) Properties

- X-coordinate value.
- Y-coordinate value.
- [Point](#) is defined as a zero-dimensional geometry.
- The boundary of a [Point](#) is the empty set.

11.4.2.4 Curve Class

A [Curve](#) is a one-dimensional geometry, usually represented by a sequence of points. Particular subclasses of [Curve](#) define the type of interpolation between points. [Curve](#) is a noninstantiable class.

[Curve](#) Properties

- A [Curve](#) has the coordinates of its points.
- A [Curve](#) is defined as a one-dimensional geometry.
- A [Curve](#) is simple if it does not pass through the same point twice, with the exception that a curve can still be simple if the start and end points are the same.
- A [Curve](#) is closed if its start point is equal to its endpoint.
- The boundary of a closed [Curve](#) is empty.
- The boundary of a nonclosed [Curve](#) consists of its two endpoints.
- A [Curve](#) that is simple and closed is a [LinearRing](#).

11.4.2.5 LineString Class

A [LineString](#) is a [Curve](#) with linear interpolation between points.

[LineString](#) Examples

- On a world map, [LineString](#) objects could represent rivers.
- In a city map, [LineString](#) objects could represent streets.

[LineString](#) Properties

- A [LineString](#) has coordinates of segments, defined by each consecutive pair of points.
- A [LineString](#) is a [Line](#) if it consists of exactly two points.
- A [LineString](#) is a [LinearRing](#) if it is both closed and simple.

11.4.2.6 Surface Class

A [Surface](#) is a two-dimensional geometry. It is a noninstantiable class. Its only instantiable subclass is [Polygon](#).

Surface Properties

- A [Surface](#) is defined as a two-dimensional geometry.
- The OpenGIS specification defines a simple [Surface](#) as a geometry that consists of a single “patch” that is associated with a single exterior boundary and zero or more interior boundaries.
- The boundary of a simple [Surface](#) is the set of closed curves corresponding to its exterior and interior boundaries.

11.4.2.7 Polygon Class

A [Polygon](#) is a planar [Surface](#) representing a multisided geometry. It is defined by a single exterior boundary and zero or more interior boundaries, where each interior boundary defines a hole in the [Polygon](#).

Polygon Examples

- On a region map, [Polygon](#) objects could represent forests, districts, and so on.

Polygon Assertions

- The boundary of a [Polygon](#) consists of a set of [LinearRing](#) objects (that is, [LineString](#) objects that are both simple and closed) that make up its exterior and interior boundaries.
- A [Polygon](#) has no rings that cross. The rings in the boundary of a [Polygon](#) may intersect at a [Point](#), but only as a tangent.
- A [Polygon](#) has no lines, spikes, or punctures.
- A [Polygon](#) has an interior that is a connected point set.
- A [Polygon](#) may have holes. The exterior of a [Polygon](#) with holes is not connected. Each hole defines a connected component of the exterior.

The preceding assertions make a [Polygon](#) a simple geometry.

11.4.2.8 GeometryCollection Class

A [GeomCollection](#) is a geometry that is a collection of zero or more geometries of any class.

[GeomCollection](#) and [GeometryCollection](#) are synonymous, with [GeomCollection](#) the preferred type name.

All the elements in a geometry collection must be in the same spatial reference system (that is, in the same coordinate system). There are no other constraints on the elements of a geometry collection, although the subclasses of [GeomCollection](#) described in the following sections may restrict membership. Restrictions may be based on:

- Element type (for example, a [MultiPoint](#) may contain only [Point](#) elements)
- Dimension
- Constraints on the degree of spatial overlap between elements

11.4.2.9 MultiPoint Class

A [MultiPoint](#) is a geometry collection composed of [Point](#) elements. The points are not connected or ordered in any way.

MultiPoint Examples

- On a world map, a [MultiPoint](#) could represent a chain of small islands.

- On a city map, a [MultiPoint](#) could represent the outlets for a ticket office.

MultiPoint Properties

- A [MultiPoint](#) is a zero-dimensional geometry.
- A [MultiPoint](#) is simple if no two of its [Point](#) values are equal (have identical coordinate values).
- The boundary of a [MultiPoint](#) is the empty set.

11.4.2.10 MultiCurve Class

A [MultiCurve](#) is a geometry collection composed of [Curve](#) elements. [MultiCurve](#) is a noninstantiable class.

MultiCurve Properties

- A [MultiCurve](#) is a one-dimensional geometry.
- A [MultiCurve](#) is simple if and only if all of its elements are simple; the only intersections between any two elements occur at points that are on the boundaries of both elements.
- A [MultiCurve](#) boundary is obtained by applying the “mod 2 union rule” (also known as the “odd-even rule”): A point is in the boundary of a [MultiCurve](#) if it is in the boundaries of an odd number of [Curve](#) elements.
- A [MultiCurve](#) is closed if all of its elements are closed.
- The boundary of a closed [MultiCurve](#) is always empty.

11.4.2.11 MultiLineString Class

A [MultiLineString](#) is a [MultiCurve](#) geometry collection composed of [LineString](#) elements.

MultiLineString Examples

- On a region map, a [MultiLineString](#) could represent a river system or a highway system.

11.4.2.12 MultiSurface Class

A [MultiSurface](#) is a geometry collection composed of surface elements. [MultiSurface](#) is a noninstantiable class. Its only instantiable subclass is [MultiPolygon](#).

MultiSurface Assertions

- Surfaces within a [MultiSurface](#) have no interiors that intersect.
- Surfaces within a [MultiSurface](#) have boundaries that intersect at most at a finite number of points.

11.4.2.13 MultiPolygon Class

A [MultiPolygon](#) is a [MultiSurface](#) object composed of [Polygon](#) elements.

MultiPolygon Examples

- On a region map, a [MultiPolygon](#) could represent a system of lakes.

MultiPolygon Assertions

- A [MultiPolygon](#) has no two [Polygon](#) elements with interiors that intersect.
- A [MultiPolygon](#) has no two [Polygon](#) elements that cross (crossing is also forbidden by the previous assertion), or that touch at an infinite number of points.

- A `MultiPolygon` may not have cut lines, spikes, or punctures. A `MultiPolygon` is a regular, closed point set.
- A `MultiPolygon` that has more than one `Polygon` has an interior that is not connected. The number of connected components of the interior of a `MultiPolygon` is equal to the number of `Polygon` values in the `MultiPolygon`.

`MultiPolygon` Properties

- A `MultiPolygon` is a two-dimensional geometry.
- A `MultiPolygon` boundary is a set of closed curves (`LineString` values) corresponding to the boundaries of its `Polygon` elements.
- Each `Curve` in the boundary of the `MultiPolygon` is in the boundary of exactly one `Polygon` element.
- Every `Curve` in the boundary of an `Polygon` element is in the boundary of the `MultiPolygon`.

11.4.3 Supported Spatial Data Formats

Two standard spatial data formats are used to represent geometry objects in queries:

- Well-Known Text (WKT) format
- Well-Known Binary (WKB) format

Internally, MySQL stores geometry values in a format that is not identical to either WKT or WKB format. (Internal format is like WKB but with an initial 4 bytes to indicate the SRID.)

There are functions available to convert between different data formats; see [Section 12.17.6, “Geometry Format Conversion Functions”](#).

The following sections describe the spatial data formats MySQL uses:

- [Well-Known Text \(WKT\) Format](#)
- [Well-Known Binary \(WKB\) Format](#)
- [Internal Geometry Storage Format](#)

Well-Known Text (WKT) Format

The Well-Known Text (WKT) representation of geometry values is designed for exchanging geometry data in ASCII form. The OpenGIS specification provides a Backus-Naur grammar that specifies the formal production rules for writing WKT values (see [Section 11.4, “Spatial Data Types”](#)).

Examples of WKT representations of geometry objects:

- A `Point`:

```
POINT(15 20)
```

The point coordinates are specified with no separating comma. This differs from the syntax for the SQL `Point()` function, which requires a comma between the coordinates. Take care to use the syntax appropriate to the context of a given spatial operation. For example, the following statements both use `ST_X()` to extract the X-coordinate from a `Point` object. The first produces the object directly using the `Point()` function. The second uses a WKT representation converted to a `Point` with `ST_GeomFromText()`.

```
mysql> SELECT ST_X(Point(15, 20));
+-----+
| ST_X(POINT(15, 20)) |
```

```

+-----+
|              15 |
+-----+

mysql> SELECT ST_X(ST_GeomFromText('POINT(15 20)'));
+-----+
| ST_X(ST_GeomFromText('POINT(15 20)')) |
+-----+
|              15 |
+-----+

```

- A [LineString](#) with four points:

```
LINESTRING(0 0, 10 10, 20 25, 50 60)
```

The point coordinate pairs are separated by commas.

- A [Polygon](#) with one exterior ring and one interior ring:

```
POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))
```

- A [MultiPoint](#) with three [Point](#) values:

```
MULTIPOINT(0 0, 20 20, 60 60)
```

Spatial functions such as [ST_MPointFromText\(\)](#) and [ST_GeomFromText\(\)](#) that accept WKT-format representations of [MultiPoint](#) values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

- A [MultiLineString](#) with two [LineString](#) values:

```
MULTILINESTRING((10 10, 20 20), (15 15, 30 15))
```

- A [MultiPolygon](#) with two [Polygon](#) values:

```
MULTIPOLYGON(((0 0,10 0,10 10,0 10,0 0)),((5 5,7 5,7 7,5 7, 5 5)))
```

- A [GeometryCollection](#) consisting of two [Point](#) values and one [LineString](#):

```
GEOMETRYCOLLECTION(POINT(10 10), POINT(30 30), LINESTRING(15 15, 20 20))
```

Well-Known Binary (WKB) Format

The Well-Known Binary (WKB) representation of geometric values is used for exchanging geometry data as binary streams represented by [BLOB](#) values containing geometric WKB information. This format is defined by the OpenGIS specification (see [Section 11.4, “Spatial Data Types”](#)). It is also defined in the ISO *SQL/MM Part 3: Spatial* standard.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers (IEEE 754 format). A byte is eight bits.

For example, a WKB value that corresponds to [POINT\(1 -1\)](#) consists of this sequence of 21 bytes, each represented by two hexadecimal digits:

```
010100000000000000000000F03F000000000000F0BF
```

The sequence consists of the components shown in the following table.

Table 11.2 WKB Components Example

Component	Size	Value
Byte order	1 byte	01

Component	Size	Value
WKB type	4 bytes	01000000
X coordinate	8 bytes	0000000000000F03F
Y coordinate	8 bytes	0000000000000F0BF

Component representation is as follows:

- The byte order indicator is either 1 or 0 to signify little-endian or big-endian storage. The little-endian and big-endian byte orders are also known as Network Data Representation (NDR) and External Data Representation (XDR), respectively.
- The WKB type is a code that indicates the geometry type. MySQL uses values from 1 through 7 to indicate [Point](#), [LineString](#), [Polygon](#), [MultiPoint](#), [MultiLineString](#), [MultiPolygon](#), and [GeometryCollection](#).
- A [Point](#) value has X and Y coordinates, each represented as a double-precision value.

WKB values for more complex geometry values have more complex data structures, as detailed in the OpenGIS specification.

Internal Geometry Storage Format

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

For the WKB part, these MySQL-specific considerations apply:

- The byte-order indicator byte is 1 because MySQL stores geometries as little-endian values.
- MySQL supports geometry types of [Point](#), [LineString](#), [Polygon](#), [MultiPoint](#), [MultiLineString](#), [MultiPolygon](#), and [GeometryCollection](#). Other geometry types are not supported.
- Only [GeometryCollection](#) can be empty. Such a value is stored with 0 elements.
- Polygon rings can be specified both clockwise and counterclockwise. MySQL flips the rings automatically when reading data.

Cartesian coordinates are stored in the length unit of the spatial reference system, with X values in the X coordinates and Y values in the Y coordinates. Axis directions are those specified by the spatial reference system.

Geographic coordinates are stored in the angle unit of the spatial reference system, with longitudes in the X coordinates and latitudes in the Y coordinates. Axis directions and the meridian are those specified by the spatial reference system.

The [LENGTH\(\)](#) function returns the space in bytes required for value storage. Example:

```
mysql> SET @g = ST_GeomFromText('POINT(1 -1)');
mysql> SELECT LENGTH(@g);
+-----+
| LENGTH(@g) |
+-----+
|          25 |
+-----+
mysql> SELECT HEX(@g);
+-----+
| HEX(@g) |
+-----+
| 00000000010100000000000000000000F03F0000000000F0BF |
+-----+
```

The value length is 25 bytes, made up of these components (as can be seen from the hexadecimal value):

- 4 bytes for integer SRID (0)
- 1 byte for integer byte order (1 = little-endian)
- 4 bytes for integer type information (1 = `Point`)
- 8 bytes for double-precision X coordinate (1)
- 8 bytes for double-precision Y coordinate (-1)

11.4.4 Geometry Well-Formedness and Validity

For geometry values, MySQL distinguishes between the concepts of syntactically well-formed and geometrically valid.

A geometry is syntactically well-formed if it satisfies conditions such as those in this (nonexhaustive) list:

- Linestrings have at least two points
- Polygons have at least one ring
- Polygon rings are closed (first and last points the same)
- Polygon rings have at least 4 points (minimum polygon is a triangle with first and last points the same)
- Collections are not empty (except `GeometryCollection`)

A geometry is geometrically valid if it is syntactically well-formed and satisfies conditions such as those in this (nonexhaustive) list:

- Polygons are not self-intersecting
- Polygon interior rings are inside the exterior ring
- Multipolygons do not have overlapping polygons

Spatial functions fail if a geometry is not syntactically well-formed. Spatial import functions that parse WKT or WKB values raise an error for attempts to create a geometry that is not syntactically well-formed. Syntactic well-formedness is also checked for attempts to store geometries into tables.

It is permitted to insert, select, and update geometrically invalid geometries, but they must be syntactically well-formed. Due to the computational expense, MySQL does not check explicitly for geometric validity. Spatial computations may detect some cases of invalid geometries and raise an error, but they may also return an undefined result without detecting the invalidity. Applications that require geometrically valid geometries should check them using the `ST_IsValid()` function.

11.4.5 Spatial Reference System Support

A spatial reference system (SRS) for spatial data is a coordinate-based system for geographic locations.

There are different types of spatial reference systems:

- A projected SRS is a projection of a globe onto a flat surface; that is, a flat map. For example, a light bulb inside a globe that shines on a paper cylinder surrounding the globe projects a map onto the paper. The result is georeferenced: Each point maps to a place on the globe. The coordinate system on that plane is Cartesian using a length unit (meters, feet, and so forth), rather than degrees of longitude and latitude.

The globes in this case are ellipsoids; that is, flattened spheres. Earth is a bit shorter in its North-South axis than its East-West axis, so a slightly flattened sphere is more correct, but perfect spheres permit faster calculations.

- A geographic SRS is a nonprojected SRS representing longitude-latitude (or latitude-longitude) coordinates on an ellipsoid, in any angular unit.
- The SRS denoted in MySQL by SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. Unlike projected SRSs, it is not georeferenced and it does not necessarily represent Earth. It is an abstract plane that can be used for anything. SRID 0 is the default SRID for spatial data in MySQL.

MySQL maintains information about available spatial reference systems for spatial data in the data dictionary `mysql.st_spatial_reference_systems` table, which can store entries for projected and geographic SRSs. This data dictionary table is invisible, but SRS entry contents are available through the `INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS` table, implemented as a view on `mysql.st_spatial_reference_systems` (see [Section 25.36](#), “The `INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS` Table”).

The following example shows what an SRS entry looks like:

```
mysql> SELECT *
      FROM INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS
      WHERE SRS_ID = 4326\G
***** 1. row *****
      SRS_NAME: WGS 84
      SRS_ID: 4326
      ORGANIZATION: EPSG
      ORGANIZATION_COORDSYS_ID: 4326
      DEFINITION: GEOGCS["WGS 84",DATUM["World Geodetic System 1984",
      SPHEROID["WGS 84",6378137,298.257223563,
      AUTHORITY["EPSG","7030"]],AUTHORITY["EPSG","6326"]],
      PRIMEM["Greenwich",0,AUTHORITY["EPSG","8901"]],
      UNIT["degree",0.017453292519943278,
      AUTHORITY["EPSG","9122"]],
      AXIS["Lat",NORTH],AXIS["Long",EAST],
      AUTHORITY["EPSG","4326"]]
      DESCRIPTION:
```

This entry describes the SRS used for GPS systems. It has a name (`SRS_NAME`) of WGS 84 and an ID (`SRS_ID`) of 4326, which is the ID used by the [European Petroleum Survey Group](#) (EPSG).

SRS definitions in the `DEFINITION` column are WKT values, represented as specified in the [Open Geospatial Consortium](#) document [OGC 12-063r5](#).

`SRS_ID` values represent the same kind of values as the SRID of geometry values or passed as the SRID argument to spatial functions. SRID 0 (the unitless Cartesian plane) is special. It is always a legal spatial reference system ID and can be used in any computations on spatial data that depend on SRID values.

For computations on multiple geometry values, all values must have the same SRID or an error occurs.

SRS definition parsing occurs on demand when definitions are needed by GIS functions. Parsed definitions are stored in the data dictionary cache to enable reuse and avoid incurring parsing overhead for every statement that needs SRS information.

To enable manipulation of SRS entries stored in the data dictionary, MySQL provides these SQL statements:

- `CREATE SPATIAL REFERENCE SYSTEM`: See [Section 13.1.19](#), “`CREATE SPATIAL REFERENCE SYSTEM` Statement”. The description for this statement includes additional information about SRS components.

- `DROP SPATIAL REFERENCE SYSTEM`: See [Section 13.1.31](#), “`DROP SPATIAL REFERENCE SYSTEM` Statement”.

11.4.6 Creating Spatial Columns

MySQL provides a standard way of creating spatial columns for geometry types, for example, with `CREATE TABLE` or `ALTER TABLE`. Spatial columns are supported for `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` tables. See also the notes about spatial indexes under [Section 11.4.10](#), “`Creating Spatial Indexes`”.

Columns with a spatial data type can have an SRID attribute, to explicitly indicate the spatial reference system (SRS) for values stored in the column. For implications of an SRID-restricted column, see [Section 11.4.1](#), “`Spatial Data Types`”.

- Use the `CREATE TABLE` statement to create a table with a spatial column:

```
CREATE TABLE geom (g GEOMETRY);
```

- Use the `ALTER TABLE` statement to add or drop a spatial column to or from an existing table:

```
ALTER TABLE geom ADD pt POINT;
ALTER TABLE geom DROP pt;
```

11.4.7 Populating Spatial Columns

After you have created spatial columns, you can populate them with spatial data.

Values should be stored in internal geometry format, but you can convert them to that format from either Well-Known Text (WKT) or Well-Known Binary (WKB) format. The following examples demonstrate how to insert geometry values into a table by converting WKT values to internal geometry format:

- Perform the conversion directly in the `INSERT` statement:

```
INSERT INTO geom VALUES (ST_GeomFromText('POINT(1 1)'));

SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

- Perform the conversion prior to the `INSERT`:

```
SET @g = ST_GeomFromText('POINT(1 1)');
INSERT INTO geom VALUES (@g);
```

The following examples insert more complex geometries into the table:

```
SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomFromText(@g));
```

The preceding examples use `ST_GeomFromText()` to create geometry values. You can also use type-specific functions:

```
SET @g = 'POINT(1 1)';
INSERT INTO geom VALUES (ST_PointFromText(@g));

SET @g = 'LINESTRING(0 0,1 1,2 2)';
INSERT INTO geom VALUES (ST_LineStringFromText(@g));
```

```
SET @g = 'POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7, 5 5))';
INSERT INTO geom VALUES (ST_PolygonFromText(@g));

SET @g =
'GEOMETRYCOLLECTION(POINT(1 1),LINESTRING(0 0,1 1,2 2,3 3,4 4))';
INSERT INTO geom VALUES (ST_GeomCollFromText(@g));
```

A client application program that wants to use WKB representations of geometry values is responsible for sending correctly formed WKB in queries to the server. There are several ways to satisfy this requirement. For example:

- Inserting a `POINT(1 1)` value with hex literal syntax:

```
INSERT INTO geom VALUES
(ST_GeomFromWKB(X'0101000000000000000000F03F000000000000F03F'));
```

- An ODBC application can send a WKB representation, binding it to a placeholder using an argument of `BLOB` type:

```
INSERT INTO geom VALUES (ST_GeomFromWKB(?))
```

Other programming interfaces may support a similar placeholder mechanism.

- In a C program, you can escape a binary value using `mysql_real_escape_string_quote()` and include the result in a query string that is sent to the server. See [mysql_real_escape_string_quote\(\)](#).

11.4.8 Fetching Spatial Data

Geometry values stored in a table can be fetched in internal format. You can also convert them to WKT or WKB format.

- Fetching spatial data in internal format:

Fetching geometry values using internal format can be useful in table-to-table transfers:

```
CREATE TABLE geom2 (g GEOMETRY) SELECT g FROM geom;
```

- Fetching spatial data in WKT format:

The `ST_AsText()` function converts a geometry from internal format to a WKT string.

```
SELECT ST_AsText(g) FROM geom;
```

- Fetching spatial data in WKB format:

The `ST_AsBinary()` function converts a geometry from internal format to a `BLOB` containing the WKB value.

```
SELECT ST_AsBinary(g) FROM geom;
```

11.4.9 Optimizing Spatial Analysis

For `MyISAM` and `InnoDB` tables, search operations in columns containing spatial data can be optimized using `SPATIAL` indexes. The most typical operations are:

- Point queries that search for all objects that contain a given point
- Region queries that search for all objects that overlap a given region

MySQL uses **R-Trees with quadratic splitting** for `SPATIAL` indexes on spatial columns. A `SPATIAL` index is built using the minimum bounding rectangle (MBR) of a geometry. For most geometries, the MBR is a minimum rectangle that surrounds the geometries. For a horizontal or a vertical linestring, the

MBR is a rectangle degenerated into the linestring. For a point, the MBR is a rectangle degenerated into the point.

It is also possible to create normal indexes on spatial columns. In a non-`SPATIAL` index, you must declare a prefix for any spatial column except for `POINT` columns.

`MyISAM` and `InnoDB` support both `SPATIAL` and non-`SPATIAL` indexes. Other storage engines support non-`SPATIAL` indexes, as described in [Section 13.1.15, “CREATE INDEX Statement”](#).

11.4.10 Creating Spatial Indexes

For `InnoDB` and `MyISAM` tables, MySQL can create spatial indexes using syntax similar to that for creating regular indexes, but using the `SPATIAL` keyword. Columns in spatial indexes must be declared `NOT NULL`. The following examples demonstrate how to create spatial indexes:

- With `CREATE TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326, SPATIAL INDEX(g));
```

- With `ALTER TABLE`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- With `CREATE INDEX`:

```
CREATE TABLE geom (g GEOMETRY NOT NULL SRID 4326);
CREATE SPATIAL INDEX g ON geom (g);
```

`SPATIAL INDEX` creates an R-tree index. For storage engines that support nonspatial indexing of spatial columns, the engine creates a B-tree index. A B-tree index on spatial values is useful for exact-value lookups, but not for range scans.

The optimizer can use spatial indexes defined on columns that are SRID-restricted. For more information, see [Section 11.4.1, “Spatial Data Types”](#), and [Section 8.3.3, “SPATIAL Index Optimization”](#).

For more information on indexing spatial columns, see [Section 13.1.15, “CREATE INDEX Statement”](#).

To drop spatial indexes, use `ALTER TABLE` or `DROP INDEX`:

- With `ALTER TABLE`:

```
ALTER TABLE geom DROP INDEX g;
```

- With `DROP INDEX`:

```
DROP INDEX g ON geom;
```

Example: Suppose that a table `geom` contains more than 32,000 geometries, which are stored in the column `g` of type `GEOMETRY`. The table also has an `AUTO_INCREMENT` column `fid` for storing object ID values.

```
mysql> DESCRIBE geom;
+-----+-----+-----+-----+-----+-----+
| Field | Type      | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| fid   | int(11)   |      | PRI | NULL    | auto_increment |
| g     | geometry  |      |     |         |                |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT COUNT(*) FROM geom;
+-----+
| count(*) |
+-----+
```

```
| 32376 |
+-----+
1 row in set (0.00 sec)
```

To add a spatial index on the column `g`, use this statement:

```
mysql> ALTER TABLE geom ADD SPATIAL INDEX(g);
Query OK, 32376 rows affected (4.05 sec)
Records: 32376 Duplicates: 0 Warnings: 0
```

11.4.11 Using Spatial Indexes

The optimizer investigates whether available spatial indexes can be involved in the search for queries that use a function such as `MBRContains()` or `MBRWithin()` in the `WHERE` clause. The following query finds all objects that are in the given rectangle:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
            31000 15000,
            31000 16000,
            30000 16000,
            30000 15000))';
mysql> SELECT fid,ST_AsText(g) FROM geom WHERE
-> MBRContains(ST_GeomFromText(@poly),g);
```

fid	ST_AsText(g)
21	LINESTRING(30350.4 15828.8,30350.6 15845,30333.8 15845,30 ...
22	LINESTRING(30350.6 15871.4,30350.6 15887.8,30334 15887.8, ...
23	LINESTRING(30350.6 15914.2,30350.6 15930.4,30334 15930.4, ...
24	LINESTRING(30290.2 15823,30290.2 15839.4,30273.4 15839.4, ...
25	LINESTRING(30291.4 15866.2,30291.6 15882.4,30274.8 15882. ...
26	LINESTRING(30291.6 15918.2,30291.6 15934.4,30275 15934.4, ...
249	LINESTRING(30337.8 15938.6,30337.8 15946.8,30320.4 15946. ...
1	LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ...
2	LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136. ...
3	LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ...
4	LINESTRING(30155.2 15121.4,30140.4 15118.6,30142 15109,30 ...
5	LINESTRING(30192.4 15085,30177.6 15082.2,30179.2 15072.4, ...
6	LINESTRING(30244 15087,30229 15086.2,30229.4 15076.4,3024 ...
7	LINESTRING(30200.6 15059.4,30185.6 15058.6,30186 15048.8, ...
10	LINESTRING(30179.6 15017.8,30181 15002.8,30190.8 15003.6, ...
11	LINESTRING(30154.2 15000.4,30168.6 15004.8,30166 15014.2, ...
13	LINESTRING(30105 15065.8,30108.4 15050.8,30118 15053,3011 ...
154	LINESTRING(30276.2 15143.8,30261.4 15141,30263 15131.4,30 ...
155	LINESTRING(30269.8 15084,30269.4 15093.4,30258.6 15093,30 ...
157	LINESTRING(30128.2 15011,30113.2 15010.2,30113.6 15000.4, ...

```
20 rows in set (0.00 sec)
```

Use `EXPLAIN` to check the way this query is executed:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
            31000 15000,
            31000 16000,
            30000 16000,
            30000 15000))';
mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM geom WHERE
-> MBRContains(ST_GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: range
possible_keys: g
          key: g
        key_len: 32
         ref: NULL
         rows: 50
```

```
Extra: Using where
1 row in set (0.00 sec)
```

Check what would happen without a spatial index:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> EXPLAIN SELECT fid,ST_AsText(g) FROM g IGNORE INDEX (g) WHERE
-> MBRContains(ST_GeomFromText(@poly),g)\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: geom
         type: ALL
possible_keys: NULL
         key: NULL
      key_len: NULL
         ref: NULL
        rows: 32376
      Extra: Using where
1 row in set (0.00 sec)
```

Executing the `SELECT` statement without the spatial index yields the same result but causes the execution time to rise from 0.00 seconds to 0.46 seconds:

```
mysql> SET @poly =
-> 'Polygon((30000 15000,
           31000 15000,
           31000 16000,
           30000 16000,
           30000 15000))';
mysql> SELECT fid,ST_AsText(g) FROM geom IGNORE INDEX (g) WHERE
-> MBRContains(ST_GeomFromText(@poly),g);
+-----+-----+
| fid | ST_AsText(g) |
+-----+-----+
| 1 | LINESTRING(30250.4 15129.2,30248.8 15138.4,30238.2 15136. ... |
| 2 | LINESTRING(30220.2 15122.8,30217.2 15137.8,30207.6 15136, ... |
| 3 | LINESTRING(30179 15114.4,30176.6 15129.4,30167 15128,3016 ... |

11.5 The JSON Data Type

- [Creating JSON Values](#)
- [Normalization, Merging, and Autowrapping of JSON Values](#)
- [Searching and Modifying JSON Values](#)

- [JSON Path Syntax](#)
- [Comparison and Ordering of JSON Values](#)
- [Converting between JSON and non-JSON values](#)
- [Aggregation of JSON Values](#)

MySQL supports a native `JSON` data type defined by [RFC 7159](#) that enables efficient access to data in JSON (JavaScript Object Notation) documents. The `JSON` data type provides these advantages over storing JSON-format strings in a string column:

- Automatic validation of JSON documents stored in `JSON` columns. Invalid documents produce an error.
- Optimized storage format. JSON documents stored in `JSON` columns are converted to an internal format that permits quick read access to document elements. When the server later must read a JSON value stored in this binary format, the value need not be parsed from a text representation. The binary format is structured to enable the server to look up subobjects or nested values directly by key or array index without reading all values before or after them in the document.

MySQL 8.0 also supports the *JSON Merge Patch* format defined in [RFC 7396](#), using the `JSON_MERGE_PATCH()` function. See the description of this function, as well as [Normalization, Merging, and Autowrapping of JSON Values](#), for examples and further information.

**Note**

This discussion uses `JSON` in monotype to indicate specifically the JSON data type and “JSON” in regular font to indicate JSON data in general.

The space required to store a `JSON` document is roughly the same as for `LONGBLOB` or `LONGTEXT`; see [Section 11.7, “Data Type Storage Requirements”](#), for more information. It is important to keep in mind that the size of any JSON document stored in a `JSON` column is limited to the value of the `max_allowed_packet` system variable. (When the server is manipulating a JSON value internally in memory, it can be larger than this; the limit applies when the server stores it.) You can obtain the amount of space required to store a JSON document using the `JSON_STORAGE_SIZE()` function; note that for a `JSON` column, the storage size—and thus the value returned by this function—is that used by the column prior to any partial updates that may have been performed on it (see the discussion of the JSON partial update optimization later in this section).

Prior to MySQL 8.0.13, a `JSON` column cannot have a non-`NULL` default value.

Along with the `JSON` data type, a set of SQL functions is available to enable operations on JSON values, such as creation, manipulation, and searching. The following discussion shows examples of these operations. For details about individual functions, see [Section 12.18, “JSON Functions”](#).

A set of spatial functions for operating on GeoJSON values is also available. See [Section 12.17.11, “Spatial GeoJSON Functions”](#).

`JSON` columns, like columns of other binary types, are not indexed directly; instead, you can create an index on a generated column that extracts a scalar value from the `JSON` column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

The MySQL optimizer also looks for compatible indexes on virtual columns that match JSON expressions.

In MySQL 8.0.17 and later, the `InnoDB` storage engine supports multi-valued indexes on JSON arrays. See [Multi-Valued Indexes](#).

MySQL NDB Cluster 8.0 supports `JSON` columns and MySQL JSON functions, including creation of an index on a column generated from a `JSON` column as a workaround for being unable to index a `JSON` column. A maximum of 3 `JSON` columns per `NDB` table is supported.

Partial Updates of JSON Values

In MySQL 8.0, the optimizer can perform a partial, in-place update of a `JSON` column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update that meets the following conditions:

- The column being updated was declared as `JSON`.
- The `UPDATE` statement uses any of the three functions `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()` to update the column. A direct assignment of the column value (for example, `UPDATE mytable SET jcol = '{"a": 10, "b": 25}'`) cannot be performed as a partial update.

Updates of multiple `JSON` columns in a single `UPDATE` statement can be optimized in this fashion; MySQL can perform partial updates of only those columns whose values are updated using the three functions just listed.

- The input column and the target column must be the same column; a statement such as `UPDATE mytable SET jcol1 = JSON_SET(jcol2, '$.a', 100)` cannot be performed as a partial update.

The update can use nested calls to any of the functions listed in the previous item, in any combination, as long as the input and target columns are the same.

- All changes replace existing array or object values with new ones, and do not add any new elements to the parent object or array.
- The value being replaced must be at least as large as the replacement value. In other words, the new value cannot be any larger than the old one.

A possible exception to this requirement occurs when a previous partial update has left sufficient space for the larger value. You can use the function `JSON_STORAGE_FREE()` to see how much space has been freed by any partial updates of a `JSON` column.

Such partial updates can be written to the binary log using a compact format that saves space; this can be enabled by setting the `binlog_row_value_options` system variable to `PARTIAL_JSON`. See the description of this variable for more information.

The next few sections provide basic information regarding the creation and manipulation of JSON values.

Creating JSON Values

A JSON array contains a list of values separated by commas and enclosed within `[` and `]` characters:

```
[ "abc", 10, null, true, false ]
```

A JSON object contains a set of key-value pairs separated by commas and enclosed within `{` and `}` characters:

```
{ "k1": "value", "k2": 10 }
```

As the examples illustrate, JSON arrays and objects can contain scalar values that are strings or numbers, the JSON null literal, or the JSON boolean true or false literals. Keys in JSON objects must be strings. Temporal (date, time, or datetime) scalar values are also permitted:

```
[ "12:18:29.000000", "2015-07-29", "2015-07-29 12:18:29.000000" ]
```

Nesting is permitted within JSON array elements and JSON object key values:

```
[ 99, { "id": "HK500", "cost": 75.99 }, [ "hot", "cold" ] ]
{ "k1": "value", "k2": [ 10, 20 ] }
```

You can also obtain JSON values from a number of functions supplied by MySQL for this purpose (see [Section 12.18.2, “Functions That Create JSON Values”](#)) as well as by casting values of other types to the `JSON` type using `CAST(value AS JSON)` (see [Converting between JSON and non-JSON values](#)). The next several paragraphs describe how MySQL handles JSON values provided as input.

In MySQL, JSON values are written as strings. MySQL parses any string used in a context that requires a JSON value, and produces an error if it is not valid as JSON. These contexts include inserting a value into a column that has the `JSON` data type and passing an argument to a function that expects a JSON value (usually shown as `json_doc` or `json_val` in the documentation for MySQL JSON functions), as the following examples demonstrate:

- Attempting to insert a value into a `JSON` column succeeds if the value is a valid JSON value, but fails if it is not:

```
mysql> CREATE TABLE t1 (jdoc JSON);
Query OK, 0 rows affected (0.20 sec)

mysql> INSERT INTO t1 VALUES('{"key1": "value1", "key2": "value2"}');
Query OK, 1 row affected (0.01 sec)

mysql> INSERT INTO t1 VALUES('[1, 2,');
ERROR 3140 (22032) at line 2: Invalid JSON text:
"Invalid value." at position 6 in value (or column) '[1, 2,'.
```

Positions for “at position *N*” in such error messages are 0-based, but should be considered rough indications of where the problem in a value actually occurs.

- The `JSON_TYPE()` function expects a JSON argument and attempts to parse it into a JSON value. It returns the value's JSON type if it is valid and produces an error otherwise:

```
mysql> SELECT JSON_TYPE('["a", "b", 1]');
+-----+
| JSON_TYPE('["a", "b", 1]') |
+-----+
| ARRAY                        |
+-----+

mysql> SELECT JSON_TYPE('"hello"');
+-----+
| JSON_TYPE('"hello"')      |
+-----+
| STRING                    |
+-----+

mysql> SELECT JSON_TYPE('hello');
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

MySQL handles strings used in JSON context using the `utf8mb4` character set and `utf8mb4_bin` collation. Strings in other character sets are converted to `utf8mb4` as necessary. (For strings in the `ascii` or `utf8` character sets, no conversion is needed because `ascii` and `utf8` are subsets of `utf8mb4`.)

As an alternative to writing JSON values using literal strings, functions exist for composing JSON values from component elements. `JSON_ARRAY()` takes a (possibly empty) list of values and returns a JSON array containing those values:

```
mysql> SELECT JSON_ARRAY('a', 1, NOW());
+-----+
| JSON_ARRAY('a', 1, NOW()) |
+-----+
| ["a", 1, "2015-07-27 09:43:47.000000"] |
+-----+
```

`JSON_OBJECT()` takes a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc') |
+-----+
| {"key1": 1, "key2": "abc"}           |
+-----+
```

`JSON_MERGE_PRESERVE()` takes two or more JSON documents and returns the combined result:

```
mysql> SELECT JSON_MERGE_PRESERVE(['a', 1], '{"key": "value"}');
+-----+
| JSON_MERGE_PRESERVE(['a', 1], '{"key": "value"}') |
+-----+
| ["a", 1, {"key": "value"}]                        |
+-----+
1 row in set (0.00 sec)
```

For information about the merging rules, see [Normalization, Merging, and Autowrapping of JSON Values](#).

(MySQL 8.0.3 and later also support `JSON_MERGE_PATCH()`, which has somewhat different behavior. See [JSON_MERGE_PATCH\(\) compared with JSON_MERGE_PRESERVE\(\)](#), for information about the differences between these two functions.)

JSON values can be assigned to user-defined variables:

```
mysql> SET @j = JSON_OBJECT('key', 'value');
mysql> SELECT @j;
+-----+
| @j      |
+-----+
| {"key": "value"} |
+-----+
```

However, user-defined variables cannot be of `JSON` data type, so although `@j` in the preceding example looks like a JSON value and has the same character set and collation as a JSON value, it does *not* have the `JSON` data type. Instead, the result from `JSON_OBJECT()` is converted to a string when assigned to the variable.

Strings produced by converting JSON values have a character set of `utf8mb4` and a collation of `utf8mb4_bin`:

```
mysql> SELECT CHARSET(@j), COLLATION(@j);
+-----+
| CHARSET(@j) | COLLATION(@j) |
+-----+
| utf8mb4     | utf8mb4_bin   |
+-----+
```

Because `utf8mb4_bin` is a binary collation, comparison of JSON values is case-sensitive.

```
mysql> SELECT JSON_ARRAY('x') = JSON_ARRAY('X');
+-----+
| JSON_ARRAY('x') = JSON_ARRAY('X') |
+-----+
| 0 |
+-----+
```

Case sensitivity also applies to the JSON `null`, `true`, and `false` literals, which always must be written in lowercase:

```
mysql> SELECT JSON_VALID('null'), JSON_VALID('Null'), JSON_VALID('NULL');
+-----+
| JSON_VALID('null') | JSON_VALID('Null') | JSON_VALID('NULL') |
+-----+
| 1 | 0 | 0 |
+-----+
```

```
mysql> SELECT CAST('null' AS JSON);
+-----+
| CAST('null' AS JSON) |
+-----+
| null                |
+-----+
1 row in set (0.00 sec)

mysql> SELECT CAST('NULL' AS JSON);
ERROR 3141 (22032): Invalid JSON text in argument 1 to function cast_as_json:
"Invalid value." at position 0 in 'NULL'.
```

Case sensitivity of the JSON literals differs from that of the SQL `NULL`, `TRUE`, and `FALSE` literals, which can be written in any lettercase:

```
mysql> SELECT ISNULL(null), ISNULL(Null), ISNULL(NULL);
+-----+-----+-----+
| ISNULL(null) | ISNULL(Null) | ISNULL(NULL) |
+-----+-----+-----+
| 1           | 1           | 1           |
+-----+-----+-----+
```

Sometimes it may be necessary or desirable to insert quote characters (" or ') into a JSON document. Assume for this example that you want to insert some JSON objects containing strings representing sentences that state some facts about MySQL, each paired with an appropriate keyword, into a table created using the SQL statement shown here:

```
mysql> CREATE TABLE facts (sentence JSON);
```

Among these keyword-sentence pairs is this one:

```
mascot: The MySQL mascot is a dolphin named "Sakila".
```

One way to insert this as a JSON object into the `facts` table is to use the MySQL `JSON_OBJECT()` function. In this case, you must escape each quote character using a backslash, as shown here:

```
mysql> INSERT INTO facts VALUES
> (JSON_OBJECT("mascot", "Our mascot is a dolphin named \"Sakila\"."));
```

This does not work in the same way if you insert the value as a JSON object literal, in which case, you must use the double backslash escape sequence, like this:

```
mysql> INSERT INTO facts VALUES
> ('{"mascot": "Our mascot is a dolphin named \\"Sakila\\"."}');
```

Using the double backslash keeps MySQL from performing escape sequence processing, and instead causes it to pass the string literal to the storage engine for processing. After inserting the JSON object in either of the ways just shown, you can see that the backslashes are present in the JSON column value by doing a simple `SELECT`, like this:

```
mysql> SELECT sentence FROM facts;
+-----+
| sentence |
+-----+
| {"mascot": "Our mascot is a dolphin named \"Sakila\"."} |
+-----+
```

To look up this particular sentence employing `mascot` as the key, you can use the column-path operator `->`, as shown here:

```
mysql> SELECT col->"$.mascot" FROM qtest;
+-----+
| col->"$.mascot" |
+-----+
| "Our mascot is a dolphin named \"Sakila\"." |
+-----+
```

```
1 row in set (0.00 sec)
```

This leaves the backslashes intact, along with the surrounding quote marks. To display the desired value using `mascot` as the key, but without including the surrounding quote marks or any escapes, use the inline path operator `->>`, like this:

```
mysql> SELECT sentence->>"$.mascot" FROM facts;
+-----+
| sentence->>"$.mascot" |
+-----+
| Our mascot is a dolphin named "Sakila". |
+-----+
```

Note

The previous example does not work as shown if the `NO_BACKSLASH_ESCAPES` server SQL mode is enabled. If this mode is set, a single backslash instead of double backslashes can be used to insert the JSON object literal, and the backslashes are preserved. If you use the `JSON_OBJECT()` function when performing the insert and this mode is set, you must alternate single and double quotes, like this:

```
mysql> INSERT INTO facts VALUES
> (JSON_OBJECT('mascot', 'Our mascot is a dolphin named "Sakila".'));
```

See the description of the `JSON_UNQUOTE()` function for more information about the effects of this mode on escaped characters in JSON values.

Normalization, Merging, and Autowrapping of JSON Values

When a string is parsed and found to be a valid JSON document, it is also normalized. This means that members with keys that duplicate a key found later in the document, reading from left to right, are discarded. The object value produced by the following `JSON_OBJECT()` call includes only the second `key1` element because that key name occurs earlier in the value, as shown here:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def') |
+-----+
| {"key1": "def", "key2": "abc"} |
+-----+
```

Normalization is also performed when values are inserted into JSON columns, as shown here:

```
mysql> CREATE TABLE t1 (c1 JSON);

mysql> INSERT INTO t1 VALUES
> (('{ "x": 17, "x": "red" }')),
> (('{ "x": 17, "x": "red", "x": [3, 5, 7] }'));

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| {"x": "red"} |
| {"x": [3, 5, 7]} |
+-----+
```

This “last duplicate key wins” behavior is suggested by [RFC 7159](#) and is implemented by most JavaScript parsers. (Bug #86866, Bug #26369555)

In versions of MySQL prior to 8.0.3, members with keys that duplicated a key found earlier in the document were discarded. The object value produced by the following `JSON_OBJECT()` call does not include the second `key1` element because that key name occurs earlier in the value:

```
mysql> SELECT JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def');
```

```
+-----+
| JSON_OBJECT('key1', 1, 'key2', 'abc', 'key1', 'def') |
+-----+
| {"key1": 1, "key2": "abc"} |
+-----+
```

Prior to MySQL 8.0.3, this “first duplicate key wins” normalization was also performed when inserting values into JSON columns.

```
mysql> CREATE TABLE t1 (c1 JSON);

mysql> INSERT INTO t1 VALUES
>   ('{"x": 17, "x": "red"}'),
>   ('{"x": 17, "x": "red", "x": [3, 5, 7]}');

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| {"x": 17} |
| {"x": 17} |
+-----+
```

MySQL also discards extra whitespace between keys, values, or elements in the original JSON document, and leaves (or inserts, when necessary) a single space following each comma (,) or colon (:) when displaying it. This is done to enhance readability.

MySQL functions that produce JSON values (see [Section 12.18.2, “Functions That Create JSON Values”](#)) always return normalized values.

To make lookups more efficient, MySQL also sorts the keys of a JSON object. *You should be aware that the result of this ordering is subject to change and not guaranteed to be consistent across releases.*

Merging JSON Values

Two merging algorithms are supported in MySQL 8.0.3 (and later), implemented by the functions `JSON_MERGE_PRESERVE()` and `JSON_MERGE_PATCH()`. These differ in how they handle duplicate keys: `JSON_MERGE_PRESERVE()` retains values for duplicate keys, while `JSON_MERGE_PATCH()` discards all but the last value. The next few paragraphs explain how each of these two functions handles the merging of different combinations of JSON documents (that is, of objects and arrays).

Note

`JSON_MERGE_PRESERVE()` is the same as the `JSON_MERGE()` function found in previous versions of MySQL (renamed in MySQL 8.0.3). `JSON_MERGE()` is still supported as an alias for `JSON_MERGE_PRESERVE()` in MySQL 8.0, but is deprecated and subject to removal in a future release.

Merging arrays. In contexts that combine multiple arrays, the arrays are merged into a single array. `JSON_MERGE_PRESERVE()` does this by concatenating arrays named later to the end of the first array. `JSON_MERGE_PATCH()` considers each argument as an array consisting of a single element (thus having 0 as its index) and then applies “last duplicate key wins” logic to select only the last argument. You can compare the results shown by this query:

```
mysql> SELECT
->   JSON_MERGE_PRESERVE('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Preserve,
->   JSON_MERGE_PATCH('[1, 2]', '["a", "b", "c"]', '[true, false]') AS Patch\G
***** 1. row *****
Preserve: [1, 2, "a", "b", "c", true, false]
Patch: [true, false]
```

Multiple objects when merged produce a single object. `JSON_MERGE_PRESERVE()` handles multiple objects having the same key by combining all unique values for that key in an array; this array is then used as the value for that key in the result. `JSON_MERGE_PATCH()` discards values for which duplicate

keys are found, working from left to right, so that the result contains only the last value for that key. The following query illustrates the difference in the results for the duplicate key `a`:

```
mysql> SELECT
->   JSON_MERGE_PRESERVE('{ "a": 1, "b": 2}', '{ "c": 3, "a": 4}', '{ "c": 5, "d": 3}') AS Preserve,
->   JSON_MERGE_PATCH('{ "a": 3, "b": 2}', '{ "c": 3, "a": 4}', '{ "c": 5, "d": 3}') AS Patch\G
***** 1. row *****
Preserve: { "a": [1, 4], "b": 2, "c": [3, 5], "d": 3}
Patch: { "a": 4, "b": 2, "c": 5, "d": 3}
```

Nonarray values used in a context that requires an array value are autowrapped: The value is surrounded by `[` and `]` characters to convert it to an array. In the following statement, each argument is autowrapped as an array (`[1]`, `[2]`). These are then merged to produce a single result array; as in the previous two cases, `JSON_MERGE_PRESERVE()` combines values having the same key while `JSON_MERGE_PATCH()` discards values for all duplicate keys except the last, as shown here:

```
mysql> SELECT
->   JSON_MERGE_PRESERVE('1', '2') AS Preserve,
->   JSON_MERGE_PATCH('1', '2') AS Patch\G
***** 1. row *****
Preserve: [1, 2]
Patch: 2
```

Array and object values are merged by autowrapping the object as an array and merging the arrays by combining values or by “last duplicate key wins” according to the choice of merging function (`JSON_MERGE_PRESERVE()` or `JSON_MERGE_PATCH()`, respectively), as can be seen in this example:

```
mysql> SELECT
->   JSON_MERGE_PRESERVE('[10, 20]', '{ "a": "x", "b": "y"}') AS Preserve,
->   JSON_MERGE_PATCH('[10, 20]', '{ "a": "x", "b": "y"}') AS Patch\G
***** 1. row *****
Preserve: [10, 20, { "a": "x", "b": "y"}]
Patch: { "a": "x", "b": "y"}
```

Searching and Modifying JSON Values

A JSON path expression selects a value within a JSON document.

Path expressions are useful with functions that extract parts of or modify a JSON document, to specify where within that document to operate. For example, the following query extracts from a JSON document the value of the member with the `name` key:

```
mysql> SELECT JSON_EXTRACT('{ "id": 14, "name": "Aztalan"}', '$.name');
+-----+
| JSON_EXTRACT('{ "id": 14, "name": "Aztalan"}', '$.name') |
+-----+
| "Aztalan" |
+-----+
```

Path syntax uses a leading `$` character to represent the JSON document under consideration, optionally followed by selectors that indicate successively more specific parts of the document:

- A period followed by a key name names the member in an object with the given key. The key name must be specified within double quotation marks if the name without quotes is not legal within path expressions (for example, if it contains a space).
- `[N]` appended to a `path` that selects an array names the value at position `N` within the array. Array positions are integers beginning with zero. If `path` does not select an array value, `path[0]` evaluates to the same value as `path`:

```
mysql> SELECT JSON_SET('"x"', '$[0]', 'a');
+-----+
| JSON_SET('"x"', '$[0]', 'a') |
+-----+
| "a" |
+-----+
```

```
+-----+
1 row in set (0.00 sec)
```

- `[M to N]` specifies a subset or range of array values starting with the value at position `M`, and ending with the value at position `N`.

`last` is supported as a synonym for the index of the rightmost array element. Relative addressing of array elements is also supported. If `path` does not select an array value, `path[last]` evaluates to the same value as `path`, as shown later in this section (see [Rightmost array element](#)).

- Paths can contain `*` or `**` wildcards:
 - `.[*]` evaluates to the values of all members in a JSON object.
 - `[*]` evaluates to the values of all elements in a JSON array.
 - `prefix**suffix` evaluates to all paths that begin with the named prefix and end with the named suffix.
- A path that does not exist in the document (evaluates to nonexistent data) evaluates to `NULL`.

Let `$` refer to this JSON array with three elements:

```
[3, {"a": [5, 6], "b": 10}, [99, 100]]
```

Then:

- `$.0` evaluates to `3`.
- `$.1` evaluates to `{"a": [5, 6], "b": 10}`.
- `$.2` evaluates to `[99, 100]`.
- `$.3` evaluates to `NULL` (it refers to the fourth array element, which does not exist).

Because `$.1` and `$.2` evaluate to nonscalar values, they can be used as the basis for more-specific path expressions that select nested values. Examples:

- `$.1.a` evaluates to `[5, 6]`.
- `$.1.a[1]` evaluates to `6`.
- `$.1.b` evaluates to `10`.
- `$.2[0]` evaluates to `99`.

As mentioned previously, path components that name keys must be quoted if the unquoted key name is not legal in path expressions. Let `$` refer to this value:

```
{"a fish": "shark", "a bird": "sparrow"}
```

The keys both contain a space and must be quoted:

- `$. "a fish"` evaluates to `shark`.
- `$. "a bird"` evaluates to `sparrow`.

Paths that use wildcards evaluate to an array that can contain multiple values:

```
mysql> SELECT JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.*');
+-----+
| JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5] }', '$.*') |
+-----+
| [1, 2, [3, 4, 5]] |
+-----+
```

```
mysql> SELECT JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]');
+-----+
| JSON_EXTRACT('{ "a": 1, "b": 2, "c": [3, 4, 5]}', '$.c[*]') |
+-----+
| [3, 4, 5] |
+-----+
```

In the following example, the path `$.**.b` evaluates to multiple paths (`$.a.b` and `$.c.b`) and produces an array of the matching path values:

```
mysql> SELECT JSON_EXTRACT('{ "a": { "b": 1}, "c": { "b": 2} }', '$**.b');
+-----+
| JSON_EXTRACT('{ "a": { "b": 1}, "c": { "b": 2} }', '$**.b') |
+-----+
| [1, 2] |
+-----+
```

Ranges from JSON arrays. You can use ranges with the `to` keyword to specify subsets of JSON arrays. For example, `$. [1 to 3]` includes the second, third, and fourth elements of an array, as shown here:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]');
+-----+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[1 to 3]') |
+-----+
| [2, 3, 4] |
+-----+
1 row in set (0.00 sec)
```

The syntax is `M to N`, where `M` and `N` are, respectively, the first and last indexes of a range of elements from a JSON array. `N` must be greater than `M`; `M` must be greater than or equal to 0. Array elements are indexed beginning with 0.

You can use ranges in contexts where wildcards are supported.

Rightmost array element. The `last` keyword is supported as a synonym for the index of the last element in an array. Expressions of the form `last - N` can be used for relative addressing, and within range definitions, like this:

```
mysql> SELECT JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]');
+-----+
| JSON_EXTRACT('[1, 2, 3, 4, 5]', '$[last-3 to last-1]') |
+-----+
| [2, 3, 4] |
+-----+
1 row in set (0.01 sec)
```

If the path is evaluated against a value that is not an array, the result of the evaluation is the same as if the value had been wrapped in a single-element array:

```
mysql> SELECT JSON_REPLACE('"Sakila"', '$[last]', 10);
+-----+
| JSON_REPLACE('"Sakila"', '$[last]', 10) |
+-----+
| 10 |
+-----+
1 row in set (0.00 sec)
```

You can use `column->path` with a JSON column identifier and JSON path expression as a synonym for `JSON_EXTRACT(column, path)`. See [Section 12.18.3, “Functions That Search JSON Values”](#), for more information. See also [Indexing a Generated Column to Provide a JSON Column Index](#).

Some functions take an existing JSON document, modify it in some way, and return the resulting modified document. Path expressions indicate where in the document to make changes. For example, the `JSON_SET()`, `JSON_INSERT()`, and `JSON_REPLACE()` functions each take a JSON document, plus one or more path-value pairs that describe where to modify the document and the values to use. The functions differ in how they handle existing and nonexisting values within the document.

Consider this document:

```
mysql> SET @j = '["a", {"b": [true, false]}, [10, 20]]';
```

`JSON_SET()` replaces values for paths that exist and adds values for paths that do not exist:

```
mysql> SELECT JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_SET(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| ["a", {"b": [1, false]}, [10, 20, 2]]      |
+-----+
```

In this case, the path `$(1).b[0]` selects an existing value (`true`), which is replaced with the value following the path argument (1). The path `$(2)[2]` does not exist, so the corresponding value (2) is added to the value selected by `$(2)`.

`JSON_INSERT()` adds new values but does not replace existing values:

```
mysql> SELECT JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_INSERT(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| ["a", {"b": [true, false]}, [10, 20, 2]]      |
+-----+
```

`JSON_REPLACE()` replaces existing values and ignores new values:

```
mysql> SELECT JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2);
+-----+
| JSON_REPLACE(@j, '$[1].b[0]', 1, '$[2][2]', 2) |
+-----+
| ["a", {"b": [1, false]}, [10, 20]]            |
+-----+
```

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

`JSON_REMOVE()` takes a JSON document and one or more paths that specify values to be removed from the document. The return value is the original document minus the values selected by paths that exist within the document:

```
mysql> SELECT JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]');
+-----+
| JSON_REMOVE(@j, '$[2]', '$[1].b[1]', '$[1].b[1]') |
+-----+
| ["a", {"b": [true]}]                               |
+-----+
```

The paths have these effects:

- `$(2)` matches `[10, 20]` and removes it.
- The first instance of `$(1).b[1]` matches `false` in the `b` element and removes it.
- The second instance of `$(1).b[1]` matches nothing: That element has already been removed, the path no longer exists, and has no effect.

JSON Path Syntax

Many of the JSON functions supported by MySQL and described elsewhere in this Manual (see [Section 12.18, “JSON Functions”](#)) require a path expression in order to identify a specific element in a JSON document. A path consists of the path's scope followed by one or more path legs. For paths used in MySQL JSON functions, the scope is always the document being searched or otherwise operated on, represented by a leading `$` character. Path legs are separated by period characters (`.`). Cells in arrays are represented by `[N]`, where `N` is a non-negative integer. Names of keys must be double-quoted strings or valid ECMAScript identifiers (see [Identifier Names and Identifiers](#), in the

ECMAScript Language Specification). Path expressions, like JSON text, should be encoded using the `ascii`, `utf8`, or `utf8mb4` character set. Other character encodings are implicitly coerced to `utf8mb4`. The complete syntax is shown here:

```
pathExpression:
    scope[ (pathLeg)* ]

pathLeg:
    member | arrayLocation | doubleAsterisk

member:
    period ( keyName | asterisk )

arrayLocation:
    leftBracket ( nonNegativeInteger | asterisk ) rightBracket

keyName:
    ESIdentifier | doubleQuotedString

doubleAsterisk:
    '**'

period:
    '.'

asterisk:
    '*'

leftBracket:
    '['

rightBracket:
    ']'
```

As noted previously, in MySQL, the scope of the path is always the document being operated on, represented as `$`. You can use `'$'` as a synonym for the document in JSON path expressions.

Note

Some implementations support column references for scopes of JSON paths; currently, MySQL does not support these.

The wildcard `*` and `**` tokens are used as follows:

- `.*` represents the values of all members in the object.
- `[*]` represents the values of all cells in the array.
- `[prefix]**suffix` represents all paths beginning with `prefix` and ending with `suffix`. `prefix` is optional, while `suffix` is required; in other words, a path may not end in `**`.

In addition, a path may not contain the sequence `***`.

For path syntax examples, see the descriptions of the various JSON functions that take paths as arguments, such as `JSON_CONTAINS_PATH()`, `JSON_SET()`, and `JSON_REPLACE()`. For examples which include the use of the `*` and `**` wildcards, see the description of the `JSON_SEARCH()` function.

MySQL 8.0.2 and later also supports range notation for subsets of JSON arrays using the `to` keyword (such as `$(2 to 10)`), as well as the `last` keyword as a synonym for the rightmost element of an array. See [Searching and Modifying JSON Values](#), for more information and examples.

Comparison and Ordering of JSON Values

JSON values can be compared using the `=`, `<`, `<=`, `>`, `>=`, `<>`, `!=`, and `<=>` operators.

The following comparison operators and functions are not yet supported with JSON values:

- [BETWEEN](#)
- [IN\(\)](#)
- [GREATEST\(\)](#)
- [LEAST\(\)](#)

A workaround for the comparison operators and functions just listed is to cast JSON values to a native MySQL numeric or string data type so they have a consistent non-JSON scalar type.

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules.

The following list shows the precedences of JSON types, from highest precedence to the lowest. (The type names are those returned by the [JSON_TYPE\(\)](#) function.) Types shown together on a line have the same precedence. Any value having a JSON type listed earlier in the list compares greater than any value having a JSON type listed later in the list.

```
BLOB
BIT
OPAQUE
DATETIME
TIME
DATE
BOOLEAN
ARRAY
OBJECT
STRING
INTEGER, DOUBLE
NULL
```

For JSON values of the same precedence, the comparison rules are type specific:

- [BLOB](#)

The first *N* bytes of the two values are compared, where *N* is the number of bytes in the shorter value. If the first *N* bytes of the two values are identical, the shorter value is ordered before the longer value.

- [BIT](#)

Same rules as for [BLOB](#).

- [OPAQUE](#)

Same rules as for [BLOB](#). [OPAQUE](#) values are values that are not classified as one of the other types.

- [DATETIME](#)

A value that represents an earlier point in time is ordered before a value that represents a later point in time. If two values originally come from the MySQL [DATETIME](#) and [TIMESTAMP](#) types, respectively, they are equal if they represent the same point in time.

- [TIME](#)

The smaller of two time values is ordered before the larger one.

- [DATE](#)

The earlier date is ordered before the more recent date.

- [ARRAY](#)

Two JSON arrays are equal if they have the same length and values in corresponding positions in the arrays are equal.

If the arrays are not equal, their order is determined by the elements in the first position where there is a difference. The array with the smaller value in that position is ordered first. If all values of the shorter array are equal to the corresponding values in the longer array, the shorter array is ordered first.

Example:

```
[ ] < [ "a" ] < [ "ab" ] < [ "ab", "cd", "ef" ] < [ "ab", "ef" ]
```

- **BOOLEAN**

The JSON false literal is less than the JSON true literal.

- **OBJECT**

Two JSON objects are equal if they have the same set of keys, and each key has the same value in both objects.

Example:

```
{ "a": 1, "b": 2 } = { "b": 2, "a": 1 }
```

The order of two objects that are not equal is unspecified but deterministic.

- **STRING**

Strings are ordered lexically on the first *N* bytes of the `utf8mb4` representation of the two strings being compared, where *N* is the length of the shorter string. If the first *N* bytes of the two strings are identical, the shorter string is considered smaller than the longer string.

Example:

```
"a" < "ab" < "b" < "bc"
```

This ordering is equivalent to the ordering of SQL strings with collation `utf8mb4_bin`. Because `utf8mb4_bin` is a binary collation, comparison of JSON values is case-sensitive:

```
"A" < "a"
```

- **INTEGER, DOUBLE**

JSON values can contain exact-value numbers and approximate-value numbers. For a general discussion of these types of numbers, see [Section 9.1.2, “Numeric Literals”](#).

The rules for comparing native MySQL numeric types are discussed in [Section 12.3, “Type Conversion in Expression Evaluation”](#), but the rules for comparing numbers within JSON values differ somewhat:

- In a comparison between two columns that use the native MySQL `INT` and `DOUBLE` numeric types, respectively, it is known that all comparisons involve an integer and a double, so the integer is converted to double for all rows. That is, exact-value numbers are converted to approximate-value numbers.
- On the other hand, if the query compares two JSON columns containing numbers, it cannot be known in advance whether numbers will be integer or double. To provide the most consistent behavior across all rows, MySQL converts approximate-value numbers to exact-value numbers. The resulting ordering is consistent and does not lose precision for the exact-value numbers. For example, given the scalars 9223372036854775805, 9223372036854775806, 9223372036854775807 and 9.223372036854776e18, the order is such as this:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
< 9.223372036854776e18 = 9223372036854776000 < 9223372036854776001
```

Were JSON comparisons to use the non-JSON numeric comparison rules, inconsistent ordering could occur. The usual MySQL comparison rules for numbers yield these orderings:

- Integer comparison:

```
9223372036854775805 < 9223372036854775806 < 9223372036854775807
```

(not defined for 9.223372036854776e18)

- Double comparison:

```
9223372036854775805 = 9223372036854775806 = 9223372036854775807 = 9.223372036854776e18
```

For comparison of any JSON value to SQL `NULL`, the result is `UNKNOWN`.

For comparison of JSON and non-JSON values, the non-JSON value is converted to JSON according to the rules in the following table, then the values compared as described previously.

Converting between JSON and non-JSON values

The following table provides a summary of the rules that MySQL follows when casting between JSON values and values of other types:

Table 11.3 JSON Conversion Rules

other type	CAST(other type AS JSON)	CAST(JSON AS other type)
JSON	No change	No change
utf8 character type (<code>utf8mb4</code> , <code>utf8</code> , <code>ascii</code>)	The string is parsed into a JSON value.	The JSON value is serialized into a <code>utf8mb4</code> string.
Other character types	Other character encodings are implicitly converted to <code>utf8mb4</code> and treated as described for utf8 character type.	The JSON value is serialized into a <code>utf8mb4</code> string, then cast to the other character encoding. The result may not be meaningful.
<code>NULL</code>	Results in a <code>NULL</code> value of type JSON.	Not applicable.
Geometry types	The geometry value is converted into a JSON document by calling <code>ST_AsGeoJSON()</code> .	Illegal operation. Workaround: Pass the result of <code>CAST(json_val AS CHAR)</code> to <code>ST_GeomFromGeoJSON()</code> .
All other types	Results in a JSON document consisting of a single scalar value.	Succeeds if the JSON document consists of a single scalar value of the target type and that scalar value can be cast to the target type. Otherwise, returns <code>NULL</code> and produces a warning.

`ORDER BY` and `GROUP BY` for JSON values works according to these principles:

- Ordering of scalar JSON values uses the same rules as in the preceding discussion.
- For ascending sorts, SQL `NULL` orders before all JSON values, including the JSON null literal; for descending sorts, SQL `NULL` orders after all JSON values, including the JSON null literal.
- Sort keys for JSON values are bound by the value of the `max_sort_length` system variable, so keys that differ only after the first `max_sort_length` bytes compare as equal.
- Sorting of nonscalar values is not currently supported and a warning occurs.

For sorting, it can be beneficial to cast a JSON scalar to some other native MySQL type. For example, if a column named `jdoc` contains JSON objects having a member consisting of an `id` key and a nonnegative value, use this expression to sort by `id` values:

```
ORDER BY CAST(JSON_EXTRACT(jdoc, '$.id') AS UNSIGNED)
```

If there happens to be a generated column defined to use the same expression as in the `ORDER BY`, the MySQL optimizer recognizes that and considers using the index for the query execution plan. See [Section 8.3.11, “Optimizer Use of Generated Column Indexes”](#).

Aggregation of JSON Values

For aggregation of JSON values, SQL `NULL` values are ignored as for other data types. Non-`NULL` values are converted to a numeric type and aggregated, except for `MIN()`, `MAX()`, and `GROUP_CONCAT()`. The conversion to number should produce a meaningful result for JSON values that are numeric scalars, although (depending on the values) truncation and loss of precision may occur. Conversion to number of other JSON values may not produce a meaningful result.

11.6 Data Type Default Values

Data type specifications can have explicit or implicit default values.

A `DEFAULT value` clause in a data type specification explicitly indicates a default value for a column. Examples:

```
CREATE TABLE t1 (
  i      INT DEFAULT -1,
  c      VARCHAR(10) DEFAULT '',
  price DOUBLE(16,2) DEFAULT 0.00
);
```

`SERIAL DEFAULT VALUE` is a special case. In the definition of an integer column, it is an alias for `NOT NULL AUTO_INCREMENT UNIQUE`.

Some aspects of explicit `DEFAULT` clause handling are version dependent, as described following.

- [Handling of Explicit Defaults as of MySQL 8.0.13](#)
- [Handling of Explicit Defaults Prior to MySQL 8.0.13](#)
- [Handling of Implicit Defaults](#)

Handling of Explicit Defaults as of MySQL 8.0.13

The default value specified in a `DEFAULT` clause can be a literal constant or an expression. With one exception, enclose expression default values within parentheses to distinguish them from literal constant default values. Examples:

```
CREATE TABLE t1 (
  -- literal defaults
  i INT          DEFAULT 0,
  c VARCHAR(10) DEFAULT '',
  -- expression defaults
  f FLOAT        DEFAULT (RAND() * RAND()),
  b BINARY(16)   DEFAULT (UUID_TO_BIN(UUID())),
  d DATE         DEFAULT (CURRENT_DATE + INTERVAL 1 YEAR),
  p POINT        DEFAULT (Point(0,0)),
  j JSON         DEFAULT (JSON_ARRAY())
);
```

The exception is that, for `TIMESTAMP` and `DATETIME` columns, you can specify the `CURRENT_TIMESTAMP` function as the default, without enclosing parentheses. See [Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

The `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` data types can be assigned a default value only if the value is written as an expression, even if the expression value is a literal:

- This is permitted (literal default specified as expression):

```
CREATE TABLE t2 (b BLOB DEFAULT ('abc'));
```

- This produces an error (literal default not specified as expression):

```
CREATE TABLE t2 (b BLOB DEFAULT 'abc');
```

Expression default values must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, built-in functions (both deterministic and nondeterministic), and operators are permitted.
- Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.
- An expression default value cannot depend on a column that has the `AUTO_INCREMENT` attribute.
- An expression default value for one column can refer to other table columns, with the exception that references to generated columns or columns with expression default values must be to columns that occur earlier in the table definition. That is, expression default values cannot contain forward references to generated columns or columns with expression default values.

The ordering constraint also applies to the use of `ALTER TABLE` to reorder table columns. If the resulting table would have an expression default value that contains a forward reference to a generated column or column with an expression default value, the statement fails.

Note

If any component of an expression default value depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For `CREATE TABLE ... LIKE` and `CREATE TABLE ... SELECT`, the destination table preserves expression default values from the original table.

If an expression default value refers to a nondeterministic function, any statement that causes the expression to be evaluated is unsafe for statement-based replication. This includes statements such as `INSERT` and `UPDATE`. In this situation, if binary logging is disabled, the statement is executed as normal. If binary logging is enabled and `binlog_format` is set to `STATEMENT`, the statement is logged and executed but a warning message is written to the error log, because replication slaves might diverge. When `binlog_format` is set to `MIXED` or `ROW`, the statement is executed as normal.

When inserting a new row, the default value for a column with an expression default can be inserted either by omitting the column name or by specifying the column as `DEFAULT` (just as for columns with literal defaults):

```
mysql> CREATE TABLE t4 (uid BINARY(16) DEFAULT (UUID_TO_BIN(UUID())));
mysql> INSERT INTO t4 () VALUES();
mysql> INSERT INTO t4 () VALUES(DEFAULT);
mysql> SELECT BIN_TO_UUID(uid) AS uid FROM t4;
+-----+
| uid                                     |
+-----+
| f1109174-94c9-11e8-971d-3bf1095aa633 |
| f110cf9a-94c9-11e8-971d-3bf1095aa633 |
+-----+
```

However, the use of `DEFAULT(col_name)` to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

Not all storage engines permit expression default values. For those that do not, an `ER_UNSUPPORTED_ACTION_ON_DEFAULT_VAL_GENERATED` error occurs.

If a default value evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 12.3, “Type Conversion in Expression Evaluation”](#).

Handling of Explicit Defaults Prior to MySQL 8.0.13

With one exception, the default value specified in a `DEFAULT` clause must be a literal constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as `NOW()` or `CURRENT_DATE`. The exception is that, for `TIMESTAMP` and `DATETIME` columns, you can specify `CURRENT_TIMESTAMP` as the default. See [Section 11.2.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

The `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` data types cannot be assigned a default value.

If a default value evaluates to a data type that differs from the declared column type, implicit coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 12.3, “Type Conversion in Expression Evaluation”](#).

Handling of Implicit Defaults

If a data type specification includes no explicit `DEFAULT` value, MySQL determines the default value as follows:

If the column can take `NULL` as a value, the column is defined with an explicit `DEFAULT NULL` clause.

If the column cannot take `NULL` as a value, MySQL defines the column with no explicit `DEFAULT` clause.

For data entry into a `NOT NULL` column that has no explicit `DEFAULT` clause, if an `INSERT` or `REPLACE` statement includes no value for the column, or an `UPDATE` statement sets the column to `NULL`, MySQL handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables and the statement is rolled back. For nontransactional tables, an error occurs, but if this happens for the second or subsequent row of a multiple-row statement, the preceding rows will have been inserted.
- If strict mode is not enabled, MySQL sets the column to the implicit default value for the column data type.

Suppose that a table `t` is defined as follows:

```
CREATE TABLE t (i INT NOT NULL);
```

In this case, `i` has no explicit default, so in strict mode each of the following statements produce an error and no row is inserted. When not using strict mode, only the third statement produces an error; the implicit default is inserted for the first two statements, but the third fails because `DEFAULT(i)` cannot produce a value:

```
INSERT INTO t VALUES();  
INSERT INTO t VALUES(DEFAULT);  
INSERT INTO t VALUES(DEFAULT(i));
```

See [Section 5.1.11, “Server SQL Modes”](#).

For a given table, the `SHOW CREATE TABLE` statement displays which columns have an explicit `DEFAULT` clause.

Implicit defaults are defined as follows:

- For numeric types, the default is 0, with the exception that for integer or floating-point types declared with the `AUTO_INCREMENT` attribute, the default is the next value in the sequence.
- For date and time types other than `TIMESTAMP`, the default is the appropriate “zero” value for the type. This is also true for `TIMESTAMP` if the `explicit_defaults_for_timestamp` system variable is enabled (see [Section 5.1.8, “Server System Variables”](#)). Otherwise, for the first `TIMESTAMP` column in a table, the default value is the current date and time. See [Section 11.2, “Date and Time Data Types”](#).
- For string types other than `ENUM`, the default value is the empty string. For `ENUM`, the default is the first enumeration value.

11.7 Data Type Storage Requirements

- [InnoDB Table Storage Requirements](#)
- [NDB Table Storage Requirements](#)
- [Numeric Type Storage Requirements](#)
- [Date and Time Type Storage Requirements](#)
- [String Type Storage Requirements](#)
- [Spatial Type Storage Requirements](#)
- [JSON Storage Requirements](#)

The storage requirements for table data on disk depend on several factors. Different storage engines represent data types and store raw data differently. Table data might be compressed, either for a column or an entire row, complicating the calculation of storage requirements for a table or column.

Despite differences in storage layout on disk, the internal MySQL APIs that communicate and exchange information about table rows use a consistent data structure that applies across all storage engines.

This section includes guidelines and information for the storage requirements for each data type supported by MySQL, including the internal format and size for storage engines that use a fixed-size representation for data types. Information is listed by category or storage engine.

The internal representation of a table has a maximum row size of 65,535 bytes, even if the storage engine is capable of supporting larger rows. This figure excludes `BLOB` or `TEXT` columns, which contribute only 9 to 12 bytes toward this size. For `BLOB` and `TEXT` data, the information is stored internally in a different area of memory than the row buffer. Different storage engines handle the allocation and storage of this data in different ways, according to the method they use for handling the corresponding types. For more information, see [Chapter 16, *Alternative Storage Engines*](#), and [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

InnoDB Table Storage Requirements

See [Section 15.10, “InnoDB Row Formats”](#) for information about storage requirements for `InnoDB` tables.

NDB Table Storage Requirements

Important

`NDB` tables use *4-byte alignment*; all `NDB` data storage is done in multiples of 4 bytes. Thus, a column value that would typically take 15 bytes requires 16 bytes in an `NDB` table. For example, in `NDB` tables, the `TINYINT`, `SMALLINT`,

`MEDIUMINT`, and `INTEGER (INT)` column types each require 4 bytes storage per record due to the alignment factor.

Each `BIT(M)` column takes M bits of storage space. Although an individual `BIT` column is *not* 4-byte aligned, `NDB` reserves 4 bytes (32 bits) per row for the first 1-32 bits needed for `BIT` columns, then another 4 bytes for bits 33-64, and so on.

While a `NULL` itself does not require any storage space, `NDB` reserves 4 bytes per row if the table definition contains any columns allowing `NULL`, up to 32 `NULL` columns. (If an `NDB Cluster` table is defined with more than 32 `NULL` columns up to 64 `NULL` columns, then 8 bytes per row are reserved.)

Every table using the `NDB` storage engine requires a primary key; if you do not define a primary key, a “hidden” primary key is created by `NDB`. This hidden primary key consumes 31-35 bytes per table record.

You can use the `ndb_size.pl` Perl script to estimate `NDB` storage requirements. It connects to a current MySQL (not `NDB Cluster`) database and creates a report on how much space that database would require if it used the `NDB` storage engine. See [Section 22.4.28, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”](#) for more information.

Numeric Type Storage Requirements

Data Type	Storage Required
<code>TINYINT</code>	1 byte
<code>SMALLINT</code>	2 bytes
<code>MEDIUMINT</code>	3 bytes
<code>INT</code> , <code>INTEGER</code>	4 bytes
<code>BIGINT</code>	8 bytes
<code>FLOAT(p)</code>	4 bytes if $0 \leq p \leq 24$, 8 bytes if $25 \leq p \leq 53$
<code>FLOAT</code>	4 bytes
<code>DOUBLE [PRECISION]</code> , <code>REAL</code>	8 bytes
<code>DECIMAL(M,D)</code> , <code>NUMERIC(M,D)</code>	Varies; see following discussion
<code>BIT(M)</code>	approximately $(M+7)/8$ bytes

Values for `DECIMAL` (and `NUMERIC`) columns are represented using a binary format that packs nine decimal (base 10) digits into four bytes. Storage for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires four bytes, and the “leftover” digits require some fraction of four bytes. The storage required for excess digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1	1
2	1
3	2
4	2
5	3
6	3
7	4
8	4

Date and Time Type Storage Requirements

For [TIME](#), [DATETIME](#), and [TIMESTAMP](#) columns, the storage required for tables created before MySQL 5.6.4 differs from tables created from 5.6.4 on. This is due to a change in 5.6.4 that permits these types to have a fractional part, which requires from 0 to 3 bytes.

Data Type	Storage Required Before MySQL 5.6.4	Storage Required as of MySQL 5.6.4
YEAR	1 byte	1 byte
DATE	3 bytes	3 bytes
TIME	3 bytes	3 bytes + fractional seconds storage
DATETIME	8 bytes	5 bytes + fractional seconds storage
TIMESTAMP	4 bytes	4 bytes + fractional seconds storage

As of MySQL 5.6.4, storage for [YEAR](#) and [DATE](#) remains unchanged. However, [TIME](#), [DATETIME](#), and [TIMESTAMP](#) are represented differently. [DATETIME](#) is packed more efficiently, requiring 5 rather than 8 bytes for the nonfractional part, and all three parts have a fractional part that requires from 0 to 3 bytes, depending on the fractional seconds precision of stored values.

Fractional Seconds Precision	Storage Required
0	0 bytes
1, 2	1 byte
3, 4	2 bytes
5, 6	3 bytes

For example, [TIME\(0\)](#), [TIME\(2\)](#), [TIME\(4\)](#), and [TIME\(6\)](#) use 3, 4, 5, and 6 bytes, respectively. [TIME](#) and [TIME\(0\)](#) are equivalent and require the same storage.

For details about internal representation of temporal values, see [MySQL Internals: Important Algorithms and Structures](#).

String Type Storage Requirements

In the following table, *M* represents the declared column length in characters for nonbinary string types and bytes for binary string types. *L* represents the actual length in bytes of a given string value.

Data Type	Storage Required
CHAR(M)	The compact family of InnoDB row formats optimize storage for variable-length character sets. See COMPACT Row Format Storage Characteristics . Otherwise, $M \times w$ bytes, $\leq M \leq 255$, where <i>w</i> is the number of bytes required for the maximum-length character in the character set.
BINARY(M)	<i>M</i> bytes, $0 \leq M \leq 255$
VARCHAR(M) , VARBINARY(M)	<i>L</i> + 1 bytes if column values require 0 – 255 bytes, <i>L</i> + 2 bytes if values may require more than 255 bytes
TINYBLOB , TINYTEXT	<i>L</i> + 1 bytes, where $L < 2^8$
BLOB , TEXT	<i>L</i> + 2 bytes, where $L < 2^{16}$
MEDIUMBLOB , MEDIUMTEXT	<i>L</i> + 3 bytes, where $L < 2^{24}$
LONGBLOB , LONGTEXT	<i>L</i> + 4 bytes, where $L < 2^{32}$
ENUM('value1', 'value2', ...)	1 or 2 bytes, depending on the number of enumeration values (65,535 values maximum)

Data Type	Storage Required
<code>SET('value1', 'value2', ...)</code>	1, 2, 3, 4, or 8 bytes, depending on the number of set members (64 members maximum)

Variable-length string types are stored using a length prefix plus data. The length prefix requires from one to four bytes depending on the data type, and the value of the prefix is *L* (the byte length of the string). For example, storage for a `MEDIUMTEXT` value requires *L* bytes to store the value plus three bytes to store the length of the value.

To calculate the number of bytes used to store a particular `CHAR`, `VARCHAR`, or `TEXT` column value, you must take into account the character set used for that column and whether the value contains multibyte characters. In particular, when using a `utf8` Unicode character set, you must keep in mind that not all characters use the same number of bytes. `utf8mb3` and `utf8mb4` character sets can require up to three and four bytes per character, respectively. For a breakdown of the storage used for different categories of `utf8mb3` or `utf8mb4` characters, see [Section 10.9, “Unicode Support”](#).

`VARCHAR`, `VARBINARY`, and the `BLOB` and `TEXT` types are variable-length types. For each, the storage requirements depend on these factors:

- The actual length of the column value
- The column's maximum possible length
- The character set used for the column, because some character sets contain multibyte characters

For example, a `VARCHAR(255)` column can hold a string with a maximum length of 255 characters. Assuming that the column uses the `latin1` character set (one byte per character), the actual storage required is the length of the string (*L*), plus one byte to record the length of the string. For the string `'abcd'`, *L* is 4 and the storage requirement is five bytes. If the same column is instead declared to use the `ucs2` double-byte character set, the storage requirement is 10 bytes: The length of `'abcd'` is eight bytes and the column requires two bytes to store lengths because the maximum length is greater than 255 (up to 510 bytes).

The effective maximum number of *bytes* that can be stored in a `VARCHAR` or `VARBINARY` column is subject to the maximum row size of 65,535 bytes, which is shared among all columns. For a `VARCHAR` column that stores multibyte characters, the effective maximum number of *characters* is less. For example, `utf8mb4` characters can require up to four bytes per character, so a `VARCHAR` column that uses the `utf8mb4` character set can be declared to be a maximum of 16,383 characters. See [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

`InnoDB` encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

The `NDB` storage engine supports variable-width columns. This means that a `VARCHAR` column in an `NDB` Cluster table requires the same amount of storage as would any other storage engine, with the exception that such values are 4-byte aligned. Thus, the string `'abcd'` stored in a `VARCHAR(50)` column using the `latin1` character set requires 8 bytes (rather than 5 bytes for the same column value in a `MyISAM` table).

`TEXT` and `BLOB` columns are implemented differently in `NDB`; each row in a `TEXT` column is made up of two separate parts. One of these is of fixed size (256 bytes), and is actually stored in the original table. The other consists of any data in excess of 256 bytes, which is stored in a hidden table. The rows in this second table are always 2000 bytes long. This means that the size of a `TEXT` column is 256 if *size* ≤ 256 (where *size* represents the size of the row); otherwise, the size is 256 + *size* + (2000 × (*size* − 256) % 2000).

The size of an `ENUM` object is determined by the number of different enumeration values. One byte is used for enumerations with up to 255 possible values. Two bytes are used for enumerations having between 256 and 65,535 possible values. See [Section 11.3.5, “The ENUM Type”](#).

The size of a `SET` object is determined by the number of different set members. If the set size is N , the object occupies $(N+7)/8$ bytes, rounded up to 1, 2, 3, 4, or 8 bytes. A `SET` can have a maximum of 64 members. See [Section 11.3.6, “The SET Type”](#).

Spatial Type Storage Requirements

MySQL stores geometry values using 4 bytes to indicate the SRID followed by the WKB representation of the value. The `LENGTH()` function returns the space in bytes required for value storage.

For descriptions of WKB and internal storage formats for spatial values, see [Section 11.4.3, “Supported Spatial Data Formats”](#).

JSON Storage Requirements

In general, the storage requirement for a `JSON` column is approximately the same as for a `LONGBLOB` or `LONGTEXT` column; that is, the space consumed by a JSON document is roughly the same as it would be for the document's string representation stored in a column of one of these types. However, there is an overhead imposed by the binary encoding, including metadata and dictionaries needed for lookup, of the individual values stored in the JSON document. For example, a string stored in a JSON document requires 4 to 10 bytes additional storage, depending on the length of the string and the size of the object or array in which it is stored.

In addition, MySQL imposes a limit on the size of any JSON document stored in a `JSON` column such that it cannot be any larger than the value of `max_allowed_packet`.

11.8 Choosing the Right Type for a Column

For optimum storage, you should try to use the most precise type in all cases. For example, if an integer column is used for values in the range from 1 to 99999, `MEDIUMINT UNSIGNED` is the best type. Of the types that represent all the required values, this type uses the least amount of storage.

All basic calculations (+, −, *, and /) with `DECIMAL` columns are done with precision of 65 decimal (base 10) digits. See [Section 11.1.1, “Numeric Data Type Syntax”](#).

If accuracy is not too important or if speed is the highest priority, the `DOUBLE` type may be good enough. For high precision, you can always convert to a fixed-point type stored in a `BIGINT`. This enables you to do all calculations with 64-bit integers and then convert results back to floating-point values as necessary.

11.9 Using Data Types from Other Database Engines

To facilitate the use of code written for SQL implementations from other vendors, MySQL maps data types as shown in the following table. These mappings make it easier to import table definitions from other database systems into MySQL.

Other Vendor Type	MySQL Type
<code>BOOL</code>	<code>TINYINT</code>
<code>BOOLEAN</code>	<code>TINYINT</code>
<code>CHARACTER VARYING(M)</code>	<code>VARCHAR(M)</code>
<code>FIXED</code>	<code>DECIMAL</code>
<code>FLOAT4</code>	<code>FLOAT</code>
<code>FLOAT8</code>	<code>DOUBLE</code>
<code>INT1</code>	<code>TINYINT</code>
<code>INT2</code>	<code>SMALLINT</code>

Other Vendor Type	MySQL Type
INT3	MEDIUMINT
INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Data type mapping occurs at table creation time, after which the original type specifications are discarded. If you create a table with types used by other vendors and then issue a `DESCRIBE tbl_name` statement, MySQL reports the table structure using the equivalent MySQL types. For example:

```
mysql> CREATE TABLE t (a BOOL, b FLOAT8, c LONG VARCHAR, d NUMERIC);
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> DESCRIBE t;
```

Field	Type	Null	Key	Default	Extra
a	tinyint(1)	YES		NULL	
b	double	YES		NULL	
c	mediumtext	YES		NULL	
d	decimal(10,0)	YES		NULL	

```
4 rows in set (0.01 sec)
```

Chapter 12 Functions and Operators

Table of Contents

12.1 SQL Function and Operator Reference	1863
12.2 User-Defined Function Reference	1875
12.3 Type Conversion in Expression Evaluation	1877
12.4 Operators	1879
12.4.1 Operator Precedence	1880
12.4.2 Comparison Functions and Operators	1881
12.4.3 Logical Operators	1888
12.4.4 Assignment Operators	1889
12.5 Flow Control Functions	1891
12.6 Numeric Functions and Operators	1893
12.6.1 Arithmetic Operators	1894
12.6.2 Mathematical Functions	1896
12.7 Date and Time Functions	1905
12.8 String Functions and Operators	1925
12.8.1 String Comparison Functions and Operators	1938
12.8.2 Regular Expressions	1942
12.8.3 Character Set and Collation of Function Results	1951
12.9 What Calendar Is Used By MySQL?	1952
12.10 Full-Text Search Functions	1952
12.10.1 Natural Language Full-Text Searches	1954
12.10.2 Boolean Full-Text Searches	1957
12.10.3 Full-Text Searches with Query Expansion	1962
12.10.4 Full-Text Stopwords	1963
12.10.5 Full-Text Restrictions	1967
12.10.6 Fine-Tuning MySQL Full-Text Search	1968
12.10.7 Adding a User-Defined Collation for Full-Text Indexing	1971
12.10.8 ngram Full-Text Parser	1972
12.10.9 MeCab Full-Text Parser Plugin	1975
12.11 Cast Functions and Operators	1979
12.12 XML Functions	1987
12.13 Bit Functions and Operators	1997
12.14 Encryption and Compression Functions	2008
12.15 Locking Functions	2014
12.16 Information Functions	2016
12.17 Spatial Analysis Functions	2027
12.17.1 Spatial Function Reference	2027
12.17.2 Argument Handling by Spatial Functions	2030
12.17.3 Functions That Create Geometry Values from WKT Values	2031
12.17.4 Functions That Create Geometry Values from WKB Values	2033
12.17.5 MySQL-Specific Functions That Create Geometry Values	2034
12.17.6 Geometry Format Conversion Functions	2035
12.17.7 Geometry Property Functions	2037
12.17.8 Spatial Operator Functions	2049
12.17.9 Functions That Test Spatial Relations Between Geometry Objects	2054
12.17.10 Spatial Geohash Functions	2059
12.17.11 Spatial GeoJSON Functions	2061
12.17.12 Spatial Convenience Functions	2063
12.18 JSON Functions	2068
12.18.1 JSON Function Reference	2068
12.18.2 Functions That Create JSON Values	2069
12.18.3 Functions That Search JSON Values	2070
12.18.4 Functions That Modify JSON Values	2085

12.18.5 Functions That Return JSON Value Attributes	2094
12.18.6 JSON Table Functions	2096
12.18.7 JSON Schema Validation Functions	2101
12.18.8 JSON Utility Functions	2106

12.20.4 Detection of Functional Dependence	2133
12.21 Window Functions	2135
12.21.1 Window Function Descriptions	2136
12.21.2 Window Function Concepts and Syntax	2142
12.21.3 Window Function Frame Specification	2145
12.21.4 Named Windows	2149
12.21.5 Window Function Restrictions	2150
12.22 Performance Schema Functions	2150
12.23 Internal Functions	2153
12.24 Miscellaneous Functions	2155
12.25 Precision Math	2169
12.25.1 Types of Numeric Values	2169
12.25.2 DECIMAL Data Type Characteristics	2170
12.25.3 Expression Handling	2171
12.25.4 Rounding Behavior	2172
12.25.5 Precision Math Examples	2173

Expressions can be used at several points in [SQL](#) statements, such as in the [ORDER BY](#) or [HAVING](#) clauses of [SELECT](#) statements, in the [WHERE](#) clause of a [SELECT](#), [DELETE](#), or [UPDATE](#) statement, or in [SET](#) statements. Expressions can be written using literal values, column values, [NULL](#), built-in functions, stored functions, user-defined functions, and operators. This chapter describes the SQL functions and operators that are permitted for writing expressions in MySQL. Instructions for writing stored functions and user-defined functions are given in [Section 24.2, “Using Stored Routines”](#), and [Adding Functions to MySQL](#). See [Section 9.2.5, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

An expression that contains [NULL](#) always produces a [NULL](#) value unless otherwise indicated in the documentation for a particular function or operator.

Note

By default, there must be no whitespace between a function name and the parenthesis following it. This helps the MySQL parser distinguish between function calls and references to tables or columns that happen to have the same name as a function. However, spaces around function arguments are permitted.

You can tell the MySQL server to accept spaces after function names by starting it with the [--sql-mode=IGNORE_SPACE](#) option. (See [Section 5.1.11, “Server SQL Modes”](#).) Individual client programs can request this behavior by using the [CLIENT_IGNORE_SPACE](#) option for [mysql_real_connect\(\)](#). In either case, all function names become reserved words.

For the sake of brevity, most examples in this chapter display the output from the [mysql](#) program in abbreviated form. Rather than showing examples in this format:

```
mysql> SELECT MOD(29,9);
+-----+
| mod(29,9) |
+-----+
|          2 |
+-----+
1 rows in set (0.00 sec)
```

This format is used instead:

```
mysql> SELECT MOD(29,9);
      -> 2
```

12.1 SQL Function and Operator Reference

The following table lists each SQL function and operator and provides a short description of each one. For a table listing user-defined functions, see [Section 12.2, “User-Defined Function Reference”](#).

Table 12.1 SQL Functions and Operators

Name	Description
&	Bitwise AND
>	Greater than operator
>>	Right shift
>=	Greater than or equal operator
<	Less than operator
<>, !=	Not equal operator
<<	Left shift
<=	Less than or equal operator
<=>	NULL-safe equal to operator
%, MOD	Modulo operator
*	Multiplication operator
+	Addition operator
-	Minus operator
-	Change the sign of the argument
->	Return value from JSON column after evaluating path; equivalent to JSON_EXTRACT().
->>	Return value from JSON column after evaluating path and unquoting the result; equivalent to JSON_UNQUOTE(JSON_EXTRACT()).
/	Division operator
:=	Assign a value
=	Assign a value (as part of a SET statement, or as part of the SET clause in an UPDATE statement)
=	Equal operator
^	Bitwise XOR
ABS ()	Return the absolute value
ACOS ()	Return the arc cosine
ADDDATE ()	Add time values (intervals) to a date value
ADDTIME ()	Add time
AES_DECRYPT ()	Decrypt using AES
AES_ENCRYPT ()	Encrypt using AES
AND, &&	Logical AND
ANY_VALUE ()	Suppress ONLY_FULL_GROUP_BY value rejection
ASCII ()	Return numeric value of left-most character
ASIN ()	Return the arc sine

Name	Description
ATAN()	Return the arc tangent
ATAN2() , ATAN()	Return the arc tangent of the two arguments
AVG()	Return the average value of the argument
BENCHMARK()	Repeatedly execute an expression
BETWEEN ... AND ...	Whether a value is within a range of values
BIN()	Return a string containing binary representation of a number
BIN_TO_UUID()	Convert binary UUID to string
BINARY	Cast a string to a binary string
BIT_AND()	Return bitwise AND
BIT_COUNT()	Return the number of bits that are set
BIT_LENGTH()	Return length of argument in bits
BIT_OR()	Return bitwise OR
BIT_XOR()	Return bitwise XOR
CAN_ACCESS_COLUMN()	Internal use only
CAN_ACCESS_DATABASE()	Internal use only
CAN_ACCESS_TABLE()	Internal use only
CAN_ACCESS_USER() (introduced 8.0.22)	Internal use only
CAN_ACCESS_VIEW()	Internal use only
CASE	Case operator
CAST()	Cast a value as a certain type
CEIL()	Return the smallest integer value not less than the argument
CEILING()	Return the smallest integer value not less than the argument
CHAR()	Return the character for each integer passed
CHAR_LENGTH()	Return number of characters in argument
CHARACTER_LENGTH()	Synonym for CHAR_LENGTH()
CHARSET()	Return the character set of the argument
COALESCE()	Return the first non-NULL argument
COERCIBILITY()	Return the collation coercibility value of the string argument
COLLATION()	Return the collation of the string argument
COMPRESS()	Return result as a binary string
CONCAT()	Return concatenated string
CONCAT_WS()	Return concatenate with separator
CONNECTION_ID()	Return the connection ID (thread ID) for the connection
CONV()	Convert numbers between different number bases
CONVERT()	Cast a value as a certain type
CONVERT_TZ()	Convert from one time zone to another
COS()	Return the cosine
COT()	Return the cotangent
COUNT()	Return a count of the number of rows returned
COUNT(DISTINCT)	Return the count of a number of different values

Name	Description
<code>CRC32()</code>	Compute a cyclic redundancy check value
<code>CUME_DIST()</code>	Cumulative distribution value
<code>CURDATE()</code>	Return the current date
<code>CURRENT_DATE()</code> , <code>CURRENT_DATE</code>	Synonyms for <code>CURDATE()</code>
<code>CURRENT_ROLE()</code>	Return the current active roles
<code>CURRENT_TIME()</code> , <code>CURRENT_TIME</code>	Synonyms for <code>CURTIME()</code>
<code>CURRENT_TIMESTAMP()</code> , <code>CURRENT_TIMESTAMP</code>	Synonyms for <code>NOW()</code>
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	The authenticated user name and host name
<code>CURTIME()</code>	Return the current time
<code>DATABASE()</code>	Return the default (current) database name
<code>DATE()</code>	Extract the date part of a date or datetime expression
<code>DATE_ADD()</code>	Add time values (intervals) to a date value
<code>DATE_FORMAT()</code>	Format date as specified
<code>DATE_SUB()</code>	Subtract a time value (interval) from a date
<code>DATEDIFF()</code>	Subtract two dates
<code>DAY()</code>	Synonym for <code>DAYOFMONTH()</code>
<code>DAYNAME()</code>	Return the name of the weekday
<code>DAYOFMONTH()</code>	Return the day of the month (0-31)
<code>DAYOFWEEK()</code>	Return the weekday index of the argument
<code>DAYOFYEAR()</code>	Return the day of the year (1-366)
<code>DEFAULT()</code>	Return the default value for a table column
<code>DEGREES()</code>	Convert radians to degrees
<code>DENSE_RANK()</code>	Rank of current row within its partition, without gaps
<code>DIV</code>	Integer division
<code>ELT()</code>	Return string at index number
<code>EXP()</code>	Raise to the power of
<code>EXPORT_SET()</code>	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
<code>EXTRACT()</code>	Extract part of a date
<code>ExtractValue()</code>	Extract a value from an XML string using XPath notation
<code>FIELD()</code>	Index (position) of first argument in subsequent arguments
<code>FIND_IN_SET()</code>	Index (position) of first argument within second argument
<code>FIRST_VALUE()</code>	Value of argument from first row of window frame
<code>FLOOR()</code>	Return the largest integer value not greater than the argument
<code>FORMAT()</code>	Return a number formatted to specified number of decimal places
<code>FORMAT_BYTES()</code> (introduced 8.0.16)	Convert byte count to value with units
<code>FORMAT_PICO_TIME()</code> (introduced 8.0.16)	Convert time in picoseconds to value with units

Name	Description
<code>FOUND_ROWS()</code>	For a SELECT with a LIMIT clause, the number of rows that would be returned were there no LIMIT clause
<code>FROM_BASE64()</code>	Decode base64 encoded string and return result
<code>FROM_DAYS()</code>	Convert a day number to a date
<code>FROM_UNIXTIME()</code>	Format Unix timestamp as a date
<code>GeomCollection()</code>	Construct geometry collection from geometries
<code>GeometryCollection()</code>	Construct geometry collection from geometries
<code>GET_DD_COLUMN_PRIVILEGES()</code>	Internal use only
<code>GET_DD_CREATE_OPTIONS()</code>	Internal use only
<code>GET_DD_INDEX_SUB_PART_LENGTH()</code>	Internal use only
<code>GET_FORMAT()</code>	Return a date format string
<code>GET_LOCK()</code>	Get a named lock
<code>GREATEST()</code>	Return the largest argument
<code>GROUP_CONCAT()</code>	Return a concatenated string
<code>GROUPING()</code>	Distinguish super-aggregate ROLLUP rows from regular rows
<code>GTID_SUBSET()</code>	Return true if all GTIDs in subset are also in set; otherwise false.
<code>GTID_SUBTRACT()</code>	Return all GTIDs in set that are not in subset.
<code>HEX()</code>	Hexadecimal representation of decimal or string value
<code>HOURLY()</code>	Extract the hour
<code>ICU_VERSION()</code>	ICU library version
<code>IF()</code>	If/else construct
<code>IFNULL()</code>	Null if/else construct
<code>IN()</code>	Whether a value is within a set of values
<code>INET_ATON()</code>	Return the numeric value of an IP address
<code>INET_NTOA()</code>	Return the IP address from a numeric value
<code>INET6_ATON()</code>	Return the numeric value of an IPv6 address
<code>INET6_NTOA()</code>	Return the IPv6 address from a numeric value
<code>INSERT()</code>	Insert substring at specified position up to specified number of characters
<code>INSTR()</code>	Return the index of the first occurrence of substring
<code>INTERNAL_AUTO_INCREMENT()</code>	Internal use only
<code>INTERNAL_AVG_ROW_LENGTH()</code>	Internal use only
<code>INTERNAL_CHECK_TIME()</code>	Internal use only
<code>INTERNAL_CHECKSUM()</code>	Internal use only
<code>INTERNAL_DATA_FREE()</code>	Internal use only
<code>INTERNAL_DATA_LENGTH()</code>	Internal use only
<code>INTERNAL_DD_CHAR_LENGTH()</code>	Internal use only
<code>INTERNAL_GET_COMMENT_OR_ERROR()</code>	Internal use only
<code>INTERNAL_GET_ENABLED_ROLE_JSON()</code> (introduced 8.0.19)	Internal use only

Name	Description
INTERNAL_GET_HOSTNAME () (introduced 8.0.19)	Internal use only
INTERNAL_GET_USERNAME () (introduced 8.0.19)	Internal use only
INTERNAL_GET_VIEW_WARNING_OR_ERROR ()	Internal use only
INTERNAL_INDEX_COLUMN_CARDINALITY ()	Internal use only
INTERNAL_INDEX_LENGTH ()	Internal use only
INTERNAL_IS_ENABLED_ROLE () (introduced 8.0.19)	Internal use only
INTERNAL_IS_MANDATORY_ROLE () (introduced 8.0.19)	Internal use only
INTERNAL_KEYS_DISABLED ()	Internal use only
INTERNAL_MAX_DATA_LENGTH ()	Internal use only
INTERNAL_TABLE_ROWS ()	Internal use only
INTERNAL_UPDATE_TIME ()	Internal use only
INTERVAL ()	Return the index of the argument that is less than the first argument
IS	Test a value against a boolean
IS_FREE_LOCK ()	Whether the named lock is free
IS_IPV4 ()	Whether argument is an IPv4 address
IS_IPV4_COMPAT ()	Whether argument is an IPv4-compatible address
IS_IPV4_MAPPED ()	Whether argument is an IPv4-mapped address
IS_IPV6 ()	Whether argument is an IPv6 address
IS NOT	Test a value against a boolean
IS NOT NULL	NOT NULL value test
IS NULL	NULL value test
IS_USED_LOCK ()	Whether the named lock is in use; return connection identifier if true
IS_UUID ()	Whether argument is a valid UUID
ISNULL ()	Test whether the argument is NULL
JSON_ARRAY ()	Create JSON array
JSON_ARRAY_APPEND ()	Append data to JSON document
JSON_ARRAY_INSERT ()	Insert into JSON array
JSON_ARRAYAGG ()	Return result set as a single JSON array
JSON_CONTAINS ()	Whether JSON document contains specific object at path
JSON_CONTAINS_PATH ()	Whether JSON document contains any data at path
JSON_DEPTH ()	Maximum depth of JSON document
JSON_EXTRACT ()	Return data from JSON document
JSON_INSERT ()	Insert data into JSON document
JSON_KEYS ()	Array of keys from JSON document
JSON_LENGTH ()	Number of elements in JSON document
JSON_MERGE () (deprecated)	Merge JSON documents, preserving duplicate keys. Deprecated synonym for JSON_MERGE_PRESERVE ()

Name	Description
JSON_MERGE_PATCH()	Merge JSON documents, replacing values of duplicate keys
JSON_MERGE_PRESERVE()	Merge JSON documents, preserving duplicate keys
JSON_OBJECT()	Create JSON object
JSON_OBJECTAGG()	Return result set as a single JSON object
JSON_OVERLAPS() (introduced 8.0.17)	Compares two JSON documents, returns TRUE (1) if these have any key-value pairs or array elements in common, otherwise FALSE (0)
JSON_PRETTY()	Print a JSON document in human-readable format
JSON_QUOTE()	Quote JSON document
JSON_REMOVE()	Remove data from JSON document
JSON_REPLACE()	Replace values in JSON document
JSON_SCHEMA_VALID() (introduced 8.0.17)	Validate JSON document against JSON schema; returns TRUE/1 if document validates against schema, or FALSE/0 if it does not
JSON_SCHEMA_VALIDATION_REPORT() (introduced 8.0.17)	Validate JSON document against JSON schema; returns report in JSON format on outcome on validation including success or failure and reasons for failure
JSON_SEARCH()	Path to value within JSON document
JSON_SET()	Insert data into JSON document
JSON_STORAGE_FREE()	Freed space within binary representation of JSON column value following partial update
JSON_STORAGE_SIZE()	Space used for storage of binary representation of a JSON document
JSON_TABLE()	Return data from a JSON expression as a relational table
JSON_TYPE()	Type of JSON value
JSON_UNQUOTE()	Unquote JSON value
JSON_VALID()	Whether JSON value is valid
JSON_VALUE() (introduced 8.0.21)	Extract value from JSON document at location pointed to by path provided; return this value as VARCHAR(512) or specified type
LAG()	Value of argument from row lagging current row within partition
LAST_DAY	Return the last day of the month for the argument
LAST_INSERT_ID()	Value of the AUTOINCREMENT column for the last INSERT
LAST_VALUE()	Value of argument from last row of window frame
LCASE()	Synonym for LOWER()
LEAD()	Value of argument from row leading current row within partition
LEAST()	Return the smallest argument
LEFT()	Return the leftmost number of characters as specified
LENGTH()	Return the length of a string in bytes
LIKE	Simple pattern matching
LineString()	Construct LineString from Point values
LN()	Return the natural logarithm of the argument

Name	Description
<code>LOAD_FILE ()</code>	Load the named file
<code>LOCALTIME ()</code> , <code>LOCALTIME</code>	Synonym for <code>NOW()</code>
<code>LOCALTIMESTAMP</code> , <code>LOCALTIMESTAMP ()</code>	Synonym for <code>NOW()</code>
<code>LOCATE ()</code>	Return the position of the first occurrence of substring
<code>LOG ()</code>	Return the natural logarithm of the first argument
<code>LOG10 ()</code>	Return the base-10 logarithm of the argument
<code>LOG2 ()</code>	Return the base-2 logarithm of the argument
<code>LOWER ()</code>	Return the argument in lowercase
<code>LPAD ()</code>	Return the string argument, left-padded with the specified string
<code>LTRIM ()</code>	Remove leading spaces
<code>MAKE_SET ()</code>	Return a set of comma-separated strings that have the corresponding bit in bits set
<code>MAKEDATE ()</code>	Create a date from the year and day of year
<code>MAKETIME ()</code>	Create time from hour, minute, second
<code>MASTER_POS_WAIT ()</code>	Block until the replica has read and applied all updates up to the specified position
<code>MATCH</code>	Perform full-text search
<code>MAX ()</code>	Return the maximum value
<code>MBRContains ()</code>	Whether MBR of one geometry contains MBR of another
<code>MBRCoveredBy ()</code>	Whether one MBR is covered by another
<code>MBRCovers ()</code>	Whether one MBR covers another
<code>MBRDisjoint ()</code>	Whether MBRs of two geometries are disjoint
<code>MBREquals ()</code>	Whether MBRs of two geometries are equal
<code>MBRIntersects ()</code>	Whether MBRs of two geometries intersect
<code>MBROverlaps ()</code>	Whether MBRs of two geometries overlap
<code>MBRTouches ()</code>	Whether MBRs of two geometries touch
<code>MBRWithin ()</code>	Whether MBR of one geometry is within MBR of another
<code>MD5 ()</code>	Calculate MD5 checksum
<code>MEMBER OF ()</code> (introduced 8.0.17)	Returns true (1) if first operand matches any element of JSON array passed as second operand, otherwise returns false (0)
<code>MICROSECOND ()</code>	Return the microseconds from argument
<code>MID ()</code>	Return a substring starting from the specified position
<code>MIN ()</code>	Return the minimum value
<code>MINUTE ()</code>	Return the minute from the argument
<code>MOD ()</code>	Return the remainder
<code>MONTH ()</code>	Return the month from the date passed
<code>MONTHNAME ()</code>	Return the name of the month
<code>MultiLineString ()</code>	Construct <code>MultiLineString</code> from <code>LineString</code> values
<code>MultiPoint ()</code>	Construct <code>MultiPoint</code> from <code>Point</code> values

Name	Description
<code>MultiPolygon()</code>	Construct MultiPolygon from Polygon values
<code>NAME_CONST()</code>	Cause the column to have the given name
<code>NOT, !</code>	Negates value
<code>NOT BETWEEN ... AND ...</code>	Whether a value is not within a range of values
<code>NOT IN()</code>	Whether a value is not within a set of values
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>NOT REGEXP</code>	Negation of REGEXP
<code>NOW()</code>	Return the current date and time
<code>NTH_VALUE()</code>	Value of argument from N-th row of window frame
<code>NTILE()</code>	Bucket number of current row within its partition.
<code>NULLIF()</code>	Return NULL if <code>expr1 = expr2</code>
<code>OCT()</code>	Return a string containing octal representation of a number
<code>OCTET_LENGTH()</code>	Synonym for <code>LENGTH()</code>
<code>OR, </code>	Logical OR
<code>ORD()</code>	Return character code for leftmost character of the argument
<code>PERCENT_RANK()</code>	Percentage rank value
<code>PERIOD_ADD()</code>	Add a period to a year-month
<code>PERIOD_DIFF()</code>	Return the number of months between periods
<code>PI()</code>	Return the value of pi
<code>Point()</code>	Construct Point from coordinates
<code>Polygon()</code>	Construct Polygon from LineString arguments
<code>POSITION()</code>	Synonym for <code>LOCATE()</code>
<code>POW()</code>	Return the argument raised to the specified power
<code>POWER()</code>	Return the argument raised to the specified power
<code>PS_CURRENT_THREAD_ID()</code> (introduced 8.0.16)	Performance Schema thread ID for current thread
<code>PS_THREAD_ID()</code> (introduced 8.0.16)	Performance Schema thread ID for given thread
<code>QUARTER()</code>	Return the quarter from a date argument
<code>QUOTE()</code>	Escape the argument for use in an SQL statement
<code>RADIANS()</code>	Return argument converted to radians
<code>RAND()</code>	Return a random floating-point value
<code>RANDOM_BYTES()</code>	Return a random byte vector
<code>RANK()</code>	Rank of current row within its partition, with gaps
<code>REGEXP</code>	Whether string matches regular expression
<code>REGEXP_INSTR()</code>	Starting index of substring matching regular expression
<code>REGEXP_LIKE()</code>	Whether string matches regular expression
<code>REGEXP_REPLACE()</code>	Replace substrings matching regular expression
<code>REGEXP_SUBSTR()</code>	Return substring matching regular expression
<code>RELEASE_ALL_LOCKS()</code>	Release all current named locks
<code>RELEASE_LOCK()</code>	Release the named lock
<code>REPEAT()</code>	Repeat a string the specified number of times

Name	Description
REPLACE()	Replace occurrences of a specified string
REVERSE()	Reverse the characters in a string
RIGHT()	Return the specified rightmost number of characters
RLIKE	Whether string matches regular expression
ROLES_GRAPHML()	Return a GraphML document representing memory role subgraphs
ROUND()	Round the argument
ROW_COUNT()	The number of rows updated
ROW_NUMBER()	Number of current row within its partition
RPAD()	Append string the specified number of times
RTRIM()	Remove trailing spaces
SCHEMA()	Synonym for DATABASE()
SEC_TO_TIME()	Converts seconds to 'hh:mm:ss' format
SECOND()	Return the second (0-59)
SESSION_USER()	Synonym for USER()
SHA1() , SHA()	Calculate an SHA-1 160-bit checksum
SHA2()	Calculate an SHA-2 checksum
SIGN()	Return the sign of the argument
SIN()	Return the sine of the argument
SLEEP()	Sleep for a number of seconds
SOUNDEX()	Return a soundex string
SOUNDS LIKE	Compare sounds
SPACE()	Return a string of the specified number of spaces
SQRT()	Return the square root of the argument
ST_Area()	Return Polygon or MultiPolygon area
ST_AsBinary() , ST_AsWKB()	Convert from internal geometry format to WKB
ST_AsGeoJSON()	Generate GeoJSON object from geometry
ST_AsText() , ST_AsWKT()	Convert from internal geometry format to WKT
ST_Buffer()	Return geometry of points within given distance from geometry
ST_Buffer_Strategy()	Produce strategy option for ST_Buffer()
ST_Centroid()	Return centroid as a point
ST_Contains()	Whether one geometry contains another
ST_ConvexHull()	Return convex hull of geometry
ST_Crosses()	Whether one geometry crosses another
ST_Difference()	Return point set difference of two geometries
ST_Dimension()	Dimension of geometry
ST_Disjoint()	Whether one geometry is disjoint from another
ST_Distance()	The distance of one geometry from another
ST_Distance_Sphere()	Minimum distance on earth between two geometries
ST_EndPoint()	End Point of LineString

Name	Description
<code>ST_Envelope()</code>	Return MBR of geometry
<code>ST_Equals()</code>	Whether one geometry is equal to another
<code>ST_ExteriorRing()</code>	Return exterior ring of Polygon
<code>ST_GeoHash()</code>	Produce a geohash value
<code>ST_GeomCollFromText()</code> , <code>ST_GeometryCollectionFromText()</code> , <code>ST_GeomCollFromText()</code>	Return geometry collection from WKT
<code>ST_GeomCollFromWKB()</code> , <code>ST_GeometryCollectionFromWKB()</code>	Return geometry collection from WKB
<code>ST_GeometryN()</code>	Return N-th geometry from geometry collection
<code>ST_GeometryType()</code>	Return name of geometry type
<code>ST_GeomFromGeoJSON()</code>	Generate geometry from GeoJSON object
<code>ST_GeomFromText()</code> , <code>ST_GeometryFromText()</code>	Return geometry from WKT
<code>ST_GeomFromWKB()</code> , <code>ST_GeometryFromWKB()</code>	Return geometry from WKB
<code>ST_InteriorRingN()</code>	Return N-th interior ring of Polygon
<code>ST_Intersection()</code>	Return point set intersection of two geometries
<code>ST_Intersects()</code>	Whether one geometry intersects another
<code>ST_IsClosed()</code>	Whether a geometry is closed and simple
<code>ST_IsEmpty()</code>	Whether a geometry is empty
<code>ST_IsSimple()</code>	Whether a geometry is simple
<code>ST_IsValid()</code>	Whether a geometry is valid
<code>ST_LatFromGeoHash()</code>	Return latitude from geohash value
<code>ST_Latitude()</code> (introduced 8.0.12)	Return latitude of Point
<code>ST_Length()</code>	Return length of LineString
<code>ST_LineFromText()</code> , <code>ST_LineStringFromText()</code>	Construct LineString from WKT
<code>ST_LineFromWKB()</code> , <code>ST_LineStringFromWKB()</code>	Construct LineString from WKB
<code>ST_LongFromGeoHash()</code>	Return longitude from geohash value
<code>ST_Longitude()</code> (introduced 8.0.12)	Return longitude of Point
<code>ST_MakeEnvelope()</code>	Rectangle around two points
<code>ST_MLineFromText()</code> , <code>ST_MultiLineStringFromText()</code>	Construct MultiLineString from WKT
<code>ST_MLineFromWKB()</code> , <code>ST_MultiLineStringFromWKB()</code>	Construct MultiLineString from WKB
<code>ST_MPointFromText()</code> , <code>ST_MultiPointFromText()</code>	Construct MultiPoint from WKT
<code>ST_MPointFromWKB()</code> , <code>ST_MultiPointFromWKB()</code>	Construct MultiPoint from WKB
<code>ST_MPolyFromText()</code> , <code>ST_MultiPolygonFromText()</code>	Construct MultiPolygon from WKT

Name	Description
<code>ST_MPolyFromWKB()</code> , <code>ST_MultiPolygonFromWKB()</code>	Construct MultiPolygon from WKB
<code>ST_NumGeometries()</code>	Return number of geometries in geometry collection
<code>ST_NumInteriorRing()</code> , <code>ST_NumInteriorRings()</code>	Return number of interior rings in Polygon
<code>ST_NumPoints()</code>	Return number of points in LineString
<code>ST_Overlaps()</code>	Whether one geometry overlaps another
<code>ST_PointFromGeoHash()</code>	Convert geohash value to POINT value
<code>ST_PointFromText()</code>	Construct Point from WKT
<code>ST_PointFromWKB()</code>	Construct Point from WKB
<code>ST_PointN()</code>	Return N-th point from LineString
<code>ST_PolyFromText()</code> , <code>ST_PolygonFromText()</code>	Construct Polygon from WKT
<code>ST_PolyFromWKB()</code> , <code>ST_PolygonFromWKB()</code>	Construct Polygon from WKB
<code>ST_Simplify()</code>	Return simplified geometry
<code>ST_SRID()</code>	Return spatial reference system ID for geometry
<code>ST_StartPoint()</code>	Start Point of LineString
<code>ST_SwapXY()</code>	Return argument with X/Y coordinates swapped
<code>ST_SymDifference()</code>	Return point set symmetric difference of two geometries
<code>ST_Touches()</code>	Whether one geometry touches another
<code>ST_Transform()</code> (introduced 8.0.13)	Transform coordinates of geometry
<code>ST_Union()</code>	Return point set union of two geometries
<code>ST_Validate()</code>	Return validated geometry
<code>ST_Within()</code>	Whether one geometry is within another
<code>ST_X()</code>	Return X coordinate of Point
<code>ST_Y()</code>	Return Y coordinate of Point
<code>STATEMENT_DIGEST()</code>	Compute statement digest hash value
<code>STATEMENT_DIGEST_TEXT()</code>	Compute normalized statement digest
<code>STD()</code>	Return the population standard deviation
<code>STDDEV()</code>	Return the population standard deviation
<code>STDDEV_POP()</code>	Return the population standard deviation
<code>STDDEV_SAMP()</code>	Return the sample standard deviation
<code>STR_TO_DATE()</code>	Convert a string to a date
<code>STRCMP()</code>	Compare two strings
<code>SUBDATE()</code>	Synonym for <code>DATE_SUB()</code> when invoked with three arguments
<code>SUBSTR()</code>	Return the substring as specified
<code>SUBSTRING()</code>	Return the substring as specified
<code>SUBSTRING_INDEX()</code>	Return a substring from a string before the specified number of occurrences of the delimiter
<code>SUBTIME()</code>	Subtract times

Name	Description
SUM()	Return the sum
SYSDATE()	Return the time at which the function executes
SYSTEM_USER()	Synonym for USER()
TAN()	Return the tangent of the argument
TIME()	Extract the time portion of the expression passed
TIME_FORMAT()	Format as time
TIME_TO_SEC()	Return the argument converted to seconds
TIMEDIFF()	Subtract time
TIMESTAMP()	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
TIMESTAMPADD()	Add an interval to a datetime expression
TIMESTAMPDIFF()	Subtract an interval from a datetime expression
TO_BASE64()	Return the argument converted to a base-64 string
TO_DAYS()	Return the date argument converted to days
TO_SECONDS()	Return the date or datetime argument converted to seconds since Year 0
TRIM()	Remove leading and trailing spaces
TRUNCATE()	Truncate to specified number of decimal places
UCASE()	Synonym for UPPER()
UNCOMPRESS()	Uncompress a string compressed
UNCOMPRESSED_LENGTH()	Return the length of a string before compression
UNHEX()	Return a string containing hex representation of a number
UNIX_TIMESTAMP()	Return a Unix timestamp
UpdateXML()	Return replaced XML fragment
UPPER()	Convert to uppercase
USER()	The user name and host name provided by the client
UTC_DATE()	Return the current UTC date
UTC_TIME()	Return the current UTC time
UTC_TIMESTAMP()	Return the current UTC date and time
UUID()	Return a Universal Unique Identifier (UUID)
UUID_SHORT()	Return an integer-valued universal identifier
UUID_TO_BIN()	Convert string UUID to binary
VALIDATE_PASSWORD_STRENGTH()	Determine strength of password
VALUES()	Define the values to be used during an INSERT
VAR_POP()	Return the population standard variance
VAR_SAMP()	Return the sample variance
VARIANCE()	Return the population standard variance
VERSION()	Return a string that indicates the MySQL server version
WAIT_FOR_EXECUTED_GTID_SET()	Wait until the given GTIDs have executed on the replica.
WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() (deprecated 8.0.18)	Use WAIT_FOR_EXECUTED_GTID_SET() .

Name	Description
<code>WEEK()</code>	Return the week number
<code>WEEKDAY()</code>	Return the weekday index
<code>WEEKOFYEAR()</code>	Return the calendar week of the date (1-53)
<code>WEIGHT_STRING()</code>	Return the weight string for a string
<code>XOR</code>	Logical XOR
<code>YEAR()</code>	Return the year
<code>YEARWEEK()</code>	Return the year and week
<code> </code>	Bitwise OR
<code>~</code>	Bitwise inversion

12.2 User-Defined Function Reference

The following table lists each user-defined function and provides a short description of each one. For a table listing SQL functions and operators, see [Section 12.1, “SQL Function and Operator Reference”](#)

For general information about user-defined functions, see [Section 5.7, “MySQL Server User-Defined Functions”](#).

Table 12.2 User-Defined Functions

Name	Description
<code>asymmetric_decrypt()</code>	Decrypt ciphertext using private or public key
<code>asymmetric_derive()</code>	Derive symmetric key from asymmetric keys
<code>asymmetric_encrypt()</code>	Encrypt cleartext using private or public key
<code>asymmetric_sign()</code>	Generate signature from digest
<code>asymmetric_verify()</code>	Verify that signature matches digest
<code>audit_api_message_emit_udf()</code>	Add message event to audit log
<code>audit_log_encryption_password_fetch()</code>	Fetch audit log encryption password
<code>audit_log_encryption_password_set()</code>	Set audit log encryption password
<code>audit_log_filter_flush()</code>	Flush audit log filter tables
<code>audit_log_filter_remove_filter()</code>	Remove audit log filter
<code>audit_log_filter_remove_user()</code>	Unassign audit log filter from user
<code>audit_log_filter_set_filter()</code>	Define audit log filter
<code>audit_log_filter_set_user()</code>	Assign audit log filter to user
<code>audit_log_read()</code>	Return audit log records
<code>audit_log_read_bookmark()</code>	Bookmark for most recent audit log event
<code>create_asymmetric_priv_key()</code>	Create private key
<code>create_asymmetric_pub_key()</code>	Create public key
<code>create_dh_parameters()</code>	Generate shared DH secret
<code>create_digest()</code>	Generate digest from string
<code>gen_blacklist()</code>	Perform dictionary term replacement
<code>gen_dictionary()</code>	Return random term from dictionary
<code>gen_dictionary_drop()</code>	Remove dictionary from registry
<code>gen_dictionary_load()</code>	Load dictionary into registry
<code>gen_range()</code>	Generate random number within range

Name	Description
<code>gen_rnd_email()</code>	Generate random email address
<code>gen_rnd_pan()</code>	Generate random payment card Primary Account Number
<code>gen_rnd_ssn()</code>	Generate random US Social Security number
<code>gen_rnd_us_phone()</code>	Generate random US phone number
<code>group_replication_get_communications_protocol_version()</code>	Return Group Replication protocol version
<code>group_replication_get_write_consensus_instances_executable_in_parallel()</code>	Return maximum number of consensus instances executable in parallel
<code>group_replication_set_as_primary()</code>	Assign group member as new primary
<code>group_replication_set_communications_protocol_version()</code>	Set Group Replication protocol version
<code>group_replication_set_write_consensus_instances_executable_in_parallel()</code>	Set maximum number of consensus instances executable in parallel
<code>group_replication_switch_to_multi_primary_mode()</code>	Change group from single-primary to multi-primary mode
<code>group_replication_switch_to_single_primary_mode()</code>	Change group from multi-primary to single-primary mode
<code>keyring_aws_rotate_cmek_key()</code>	Rotate AWS customer master key
<code>keyring_aws_rotate_keys()</code>	Rotate keys in keyring_aws storage file
<code>keyring_hashicorp_update_config()</code>	Cause runtime keyring_hashicorp reconfiguration
<code>keyring_key_fetch()</code>	Fetch keyring key value
<code>keyring_key_generate()</code>	Generate random keyring key
<code>keyring_key_length_fetch()</code>	Return keyring key length
<code>keyring_key_remove()</code>	Remove keyring key
<code>keyring_key_store()</code>	Store key in keyring
<code>keyring_key_type_fetch()</code>	Return keyring key type
<code>load_rewrite_rules()</code>	Rewriter plugin helper routine
<code>mask_inner()</code>	Mask interior part of string
<code>mask_outer()</code>	Mask left and right parts of string
<code>mask_pan()</code>	Mask payment card Primary Account Number part of string
<code>mask_pan_relaxed()</code>	Mask payment card Primary Account Number part of string
<code>mask_ssn()</code>	Mask US Social Security number
<code>mysql_firewall_flush_status()</code>	Reset firewall status variables
<code>normalize_statement()</code>	Normalize SQL statement to digest form
<code>read_firewall_users()</code>	Update firewall user cache
<code>read_firewall_whitelist()</code>	Update firewall recorded statement cache
<code>service_get_read_locks()</code>	Acquire locking service shared locks
<code>service_get_write_locks()</code>	Acquire locking service exclusive locks
<code>service_release_locks()</code>	Release locking service locks
<code>set_firewall_mode()</code>	Establish firewall user operational mode
<code>version_tokens_delete()</code>	Delete tokens from version tokens list
<code>version_tokens_edit()</code>	Modify version tokens list
<code>version_tokens_lock_exclusive()</code>	Acquire exclusive locks on version tokens
<code>version_tokens_lock_shared()</code>	Acquire shared locks on version tokens
<code>version_tokens_set()</code>	Set version tokens list

Name	Description
<code>version_tokens_show()</code>	Return version tokens list
<code>version_tokens_unlock()</code>	Release version tokens locks

12.3 Type Conversion in Expression Evaluation

When an operator is used with operands of different types, type conversion occurs to make the operands compatible. Some conversions occur implicitly. For example, MySQL automatically converts strings to numbers as necessary, and vice versa.

```
mysql> SELECT 1+'1';
-> 2
mysql> SELECT CONCAT(2,' test');
-> '2 test'
```

It is also possible to convert a number to a string explicitly using the `CAST()` function. Conversion occurs implicitly with the `CONCAT()` function because it expects string arguments.

```
mysql> SELECT 38.8, CAST(38.8 AS CHAR);
-> 38.8, '38.8'
mysql> SELECT 38.8, CONCAT(38.8);
-> 38.8, '38.8'
```

See later in this section for information about the character set of implicit number-to-string conversions, and for modified rules that apply to `CREATE TABLE ... SELECT` statements.

The following rules describe how conversion occurs for comparison operations:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`, except for the `NULL-safe <=>` equality comparison operator. For `NULL <=> NULL`, the result is true. No conversion is needed.
- If both arguments in a comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- Hexadecimal values are treated as binary strings if not compared to a number.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed. This is done to be more ODBC-friendly. This is not done for the arguments to `IN()`. To be safe, always use complete datetime, date, or time strings when doing comparisons. For example, to achieve best results when using `BETWEEN` with date or time values, use `CAST()` to explicitly convert the values to the desired data type.

A single-row subquery from a table or tables is not considered a constant. For example, if a subquery returns an integer to be compared to a `DATETIME` value, the comparison is done as two integers. The integer is not converted to a temporal value. To compare the operands as `DATETIME` values, use `CAST()` to explicitly convert the subquery value to `DATETIME`.

- If one of the arguments is a decimal value, comparison depends on the other argument. The arguments are compared as decimal values if the other argument is a decimal or integer value, or as floating-point values if the other argument is a floating-point value.
- In all other cases, the arguments are compared as floating-point (real) numbers. For example, a comparison of string and numeric operands takes place as a comparison of floating-point numbers.

For information about conversion of values from one temporal type to another, see [Section 11.2.7, “Conversion Between Date and Time Types”](#).

Comparison of JSON values takes place at two levels. The first level of comparison is based on the JSON types of the compared values. If the types differ, the comparison result is determined solely by which type has higher precedence. If the two values have the same JSON type, a second level of comparison occurs using type-specific rules. For comparison of JSON and non-JSON values, the

non-JSON value is converted to JSON and the values compared as JSON values. For details, see [Comparison and Ordering of JSON Values](#).

The following examples illustrate conversion of strings to numbers for comparison operations:

```
mysql> SELECT 1 > '6x';
-> 0
mysql> SELECT 7 > '6x';
-> 1
mysql> SELECT 0 > 'x6';
-> 0
mysql> SELECT 0 = 'x6';
-> 1
```

For comparisons of a string column with a number, MySQL cannot use an index on the column to look up the value quickly. If *str_col* is an indexed string column, the index cannot be used when performing the lookup in the following statement:

```
SELECT * FROM tbl_name WHERE str_col=1;
```

The reason for this is that there are many different strings that may convert to the value 1, such as '1', ' 1', or '1a'.

Comparisons between floating-point numbers and large values of `INTEGER` type are approximate because the integer is converted to double-precision floating point before comparison, which is not capable of representing all 64-bit integers exactly. For example, the integer value $2^{53} + 1$ is not representable as a float, and will be rounded to 2^{53} or $2^{53} + 2$ before a float comparison, depending on the platform.

To illustrate, only the first of the following comparisons compares equal values, but both comparisons return true (1):

```
mysql> SELECT '9223372036854775807' = 9223372036854775807;
-> 1
mysql> SELECT '9223372036854775807' = 9223372036854775806;
-> 1
```

When conversions from string to floating-point and from integer to floating-point occur, they do not necessarily occur the same way. The integer may be converted to floating-point by the CPU, whereas the string is converted digit by digit in an operation that involves floating-point multiplications. Also, results can be affected by factors such as computer architecture or the compiler version or optimization level. One way to avoid such problems is to use `CAST()` so that a value is not converted implicitly to a float-point number:

```
mysql> SELECT CAST('9223372036854775807' AS UNSIGNED) = 9223372036854775806;
-> 0
```

For more information about floating-point comparisons, see [Section B.3.4.8, “Problems with Floating-Point Values”](#).

The server includes `dtoa`, a conversion library that provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT/DOUBLE`) numbers:

- Consistent conversion results across platforms, which eliminates, for example, Unix versus Windows conversion differences.
- Accurate representation of values in cases where results previously did not provide sufficient precision, such as for values close to IEEE limits.
- Conversion of numbers to string format with the best possible precision. The precision of `dtoa` is always the same or better than that of the standard C library functions.

Because the conversions produced by this library differ in some cases from non-`dtoa` results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

The `dtoa` library provides conversions with the following properties. `D` represents a value with a `DECIMAL` or string representation, and `F` represents a floating-point number in native binary (IEEE) format.

- $F \rightarrow D$ conversion is done with the best possible precision, returning D as the shortest string that yields F when read back in and rounded to the nearest value in native binary format as specified by IEEE.
- $D \rightarrow F$ conversion is done such that F is the nearest native binary number to the input decimal string D .

These properties imply that $F \rightarrow D \rightarrow F$ conversions are lossless unless F is `-inf`, `+inf`, or `NaN`. The latter values are not supported because the SQL standard defines them as invalid values for `FLOAT` or `DOUBLE`.

For $D \rightarrow F \rightarrow D$ conversions, a sufficient condition for losslessness is that D uses 15 or fewer digits of precision, is not a denormal value, `-inf`, `+inf`, or `NaN`. In some cases, the conversion is lossless even if D has more than 15 digits of precision, but this is not always the case.

Implicit conversion of a numeric or temporal value to string produces a value that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. (These variables commonly are set with `SET NAMES`. For information about connection character sets, see [Section 10.4, “Connection Character Sets and Collations”](#).)

This means that such a conversion results in a character (nonbinary) string (a [CHAR](#), [VARCHAR](#), or [LONGTEXT](#) value), except in the case that the connection character set is set to [binary](#). In that case, the conversion result is a binary string (a [BINARY](#), [VARBINARY](#), or [LONGBLOB](#) value).

For integer expressions, the preceding remarks about expression *evaluation* apply somewhat differently for expression *assignment*; for example, in a statement such as this:

```
CREATE TABLE t SELECT integer_expr;
```

In this case, the table in the column resulting from the expression has type `INT` or `BIGINT` depending on the length of the integer expression. If the maximum length of the expression does not fit in an `INT`, `BIGINT` is used instead. The length is taken from the `max_length` value of the `SELECT` result set metadata (see [C API Data Structures](#)). This means that you can force a `BIGINT` rather than `INT` by use of a sufficiently long expression:

```
CREATE TABLE t SELECT 0000000000000000000000;
```

12.4 Operators

Table 12.3 Operators

Name	Description
&	Bitwise AND
>	Greater than operator
>>	Right shift
>=	Greater than or equal operator
<	Less than operator
<>, !=	Not equal operator
<<	Left shift
<=	Less than or equal operator
<=>	NULL-safe equal to operator
%, MOD	Modulo operator

Name	Description
*	Multiplication operator
+	Addition operator
-	Minus operator
-	Change the sign of the argument
->	Return value from JSON column after evaluating path; equivalent to JSON_EXTRACT().
->>	Return value from JSON column after evaluating path and unquoting the result; equivalent to JSON_UNQUOTE(JSON_EXTRACT()).
/	Division operator
:=	Assign a value
=	Assign a value (as part of a SET statement, or as part of the SET clause in an UPDATE statement)
=	Equal operator
^	Bitwise XOR
AND, &&	Logical AND
BETWEEN ... AND ...	Whether a value is within a range of values
BINARY	Cast a string to a binary string
CASE	Case operator
DIV	Integer division
IN()	Whether a value is within a set of values
IS	Test a value against a boolean
IS NOT	Test a value against a boolean
IS NOT NULL	NOT NULL value test
IS NULL	NULL value test
LIKE	Simple pattern matching
MEMBER OF() (introduced 8.0.17)	Returns true (1) if first operand matches any element of JSON array passed as second operand, otherwise returns false (0)
NOT, !	Negates value
NOT BETWEEN ... AND ...	Whether a value is not within a range of values
NOT IN()	Whether a value is not within a set of values
NOT LIKE	Negation of simple pattern matching
NOT REGEXP	Negation of REGEXP
OR,	Logical OR
REGEXP	Whether string matches regular expression
RLIKE	Whether string matches regular expression
SOUNDS LIKE	Compare sounds
XOR	Logical XOR
	Bitwise OR
~	Bitwise inversion

12.4.1 Operator Precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```

INTERVAL
BINARY, COLLATE
!
- (unary minus), ~ (unary bit inversion)
^
*, /, DIV, %, MOD
-, +
<<, >>
&
|
= (comparison), <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN, MEMBER OF
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, &&
XOR
OR, ||
= (assignment), :=

```

The precedence of `=` depends on whether it is used as a comparison operator (`=`) or as an assignment operator (`:=`). When used as a comparison operator, it has the same precedence as `<=>`, `>=`, `>`, `<=`, `<`, `<>`, `!=`, `IS`, `LIKE`, `REGEXP`, and `IN()`. When used as an assignment operator, it has the same precedence as `:=`. [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#), and [Section 9.4, “User-Defined Variables”](#), explain how MySQL determines which interpretation of `=` should apply.

For operators that occur at the same precedence level within an expression, evaluation proceeds left to right, with the exception that assignments evaluate right to left.

The precedence and meaning of some operators depends on the SQL mode:

- By default, `||` is a logical `OR` operator. With `PIPES_AS_CONCAT` enabled, `||` is string concatenation, with a precedence between `^` and the unary operators.
- By default, `!` has a higher precedence than `NOT`. With `HIGH_NOT_PRECEDENCE` enabled, `!` and `NOT` have the same precedence.

See [Section 5.1.11, “Server SQL Modes”](#).

The precedence of operators determines the order of evaluation of terms in an expression. To override this order and group terms explicitly, use parentheses. For example:

```

mysql> SELECT 1+2*3;
-> 7
mysql> SELECT (1+2)*3;
-> 9

```

12.4.2 Comparison Functions and Operators

Table 12.4 Comparison Operators

Name	Description
<code>></code>	Greater than operator
<code>>=</code>	Greater than or equal operator
<code><</code>	Less than operator
<code><></code> , <code>!=</code>	Not equal operator
<code><=</code>	Less than or equal operator
<code><=></code>	NULL-safe equal to operator
<code>=</code>	Equal operator
<code>BETWEEN ... AND ...</code>	Whether a value is within a range of values

Name	Description
<code>COALESCE()</code>	Return the first non-NULL argument
<code>GREATEST()</code>	Return the largest argument
<code>IN()</code>	Whether a value is within a set of values
<code>INTERVAL()</code>	Return the index of the argument that is less than the first argument
<code>IS</code>	Test a value against a boolean
<code>IS NOT</code>	Test a value against a boolean
<code>IS NOT NULL</code>	NOT NULL value test
<code>IS NULL</code>	NULL value test
<code>ISNULL()</code>	Test whether the argument is NULL
<code>LEAST()</code>	Return the smallest argument
<code>LIKE</code>	Simple pattern matching
<code>NOT BETWEEN ... AND ...</code>	Whether a value is not within a range of values
<code>NOT IN()</code>	Whether a value is not within a set of values
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>STRCMP()</code>	Compare two strings

Comparison operations result in a value of 1 (**TRUE**), 0 (**FALSE**), or **NULL**. These operations work for both numbers and strings. Strings are automatically converted to numbers and numbers to strings as necessary.

The following relational comparison operators can be used to compare not only scalar operands, but row operands:

```
= > < >= <= <> !=
```

The descriptions for those operators later in this section detail how they work with row operands. For additional examples of row comparisons in the context of row subqueries, see [Section 13.2.11.5, “Row Subqueries”](#).

Some of the functions in this section return values other than 1 (**TRUE**), 0 (**FALSE**), or **NULL**. `LEAST()` and `GREATEST()` are examples of such functions; [Section 12.3, “Type Conversion in Expression Evaluation”](#), describes the rules for comparison operations performed by these and similar functions for determining their return values.

Note

In previous versions of MySQL, when evaluating an expression containing `LEAST()` or `GREATEST()`, the server attempted to guess the context in which the function was used, and to coerce the function's arguments to the data type of the expression as a whole. For example, the arguments to `LEAST("11", "45", "2")` are evaluated and sorted as strings, so that this expression returns "11". In MySQL 8.0.3 and earlier, when evaluating the expression `LEAST("11", "45", "2") + 0`, the server converted the arguments to integers (anticipating the addition of integer 0 to the result) before sorting them, thus returning 2.

Beginning with MySQL 8.0.4, the server no longer attempts to infer context in this fashion. Instead, the function is executed using the arguments as provided, performing data type conversions to one or more of the arguments if and only if they are not all of the same type. Any type coercion mandated by an expression that makes use of the return value is now performed following

function execution. This means that, in MySQL 8.0.4 and later, `LEAST("11", "45", "2") + 0` evaluates to `"11" + 0` and thus to integer 11. (Bug #83895, Bug #25123839)

To convert a value to a specific type for comparison purposes, you can use the `CAST()` function. String values can be converted to a different character set using `CONVERT()`. See [Section 12.11, “Cast Functions and Operators”](#).

By default, string comparisons are not case-sensitive and use the current character set. The default is `utf8mb4`.

- `=`

Equal:

```
mysql> SELECT 1 = 0;
-> 0
mysql> SELECT '0' = 0;
-> 1
mysql> SELECT '0.0' = 0;
-> 1
mysql> SELECT '0.01' = 0;
-> 0
mysql> SELECT '.01' = 0.01;
-> 1
```

For row comparisons, `(a, b) = (x, y)` is equivalent to:

```
(a = x) AND (b = y)
```

- `<=>`

`NULL`-safe equal. This operator performs an equality comparison like the `=` operator, but returns `1` rather than `NULL` if both operands are `NULL`, and `0` rather than `NULL` if one operand is `NULL`.

The `<=>` operator is equivalent to the standard SQL `IS NOT DISTINCT FROM` operator.

```
mysql> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
-> 1, 1, 0
mysql> SELECT 1 = 1, NULL = NULL, 1 = NULL;
-> 1, NULL, NULL
```

For row comparisons, `(a, b) <=> (x, y)` is equivalent to:

```
(a <=> x) AND (b <=> y)
```

- `<>`, `!=`

Not equal:

```
mysql> SELECT '.01' <> '0.01';
-> 1
mysql> SELECT .01 <> '0.01';
-> 0
mysql> SELECT 'zapp' <> 'zappp';
-> 1
```

For row comparisons, `(a, b) <> (x, y)` and `(a, b) != (x, y)` are equivalent to:

```
(a <> x) OR (b <> y)
```

- `<=`

Less than or equal:

```
mysql> SELECT 0.1 <= 2;
-> 1
```

For row comparisons, $(a, b) \leq (x, y)$ is equivalent to:

```
(a < x) OR ((a = x) AND (b <= y))
```

- <

Less than:

```
mysql> SELECT 2 < 2;
-> 0
```

For row comparisons, $(a, b) < (x, y)$ is equivalent to:

```
(a < x) OR ((a = x) AND (b < y))
```

- >=

Greater than or equal:

```
mysql> SELECT 2 >= 2;
-> 1
```

For row comparisons, $(a, b) \geq (x, y)$ is equivalent to:

```
(a > x) OR ((a = x) AND (b >= y))
```

- >

Greater than:

```
mysql> SELECT 2 > 2;
-> 0
```

For row comparisons, $(a, b) > (x, y)$ is equivalent to:

```
(a > x) OR ((a = x) AND (b > y))
```

- *expr BETWEEN min AND max*

If *expr* is greater than or equal to *min* and *expr* is less than or equal to *max*, *BETWEEN* returns 1, otherwise it returns 0. This is equivalent to the expression $(min \leq expr \text{ AND } expr \leq max)$ if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described in [Section 12.3, "Type Conversion in Expression Evaluation"](#), but applied to all the three arguments.

```
mysql> SELECT 2 BETWEEN 1 AND 3, 2 BETWEEN 3 and 1;
-> 1, 0
mysql> SELECT 1 BETWEEN 2 AND 3;
-> 0
mysql> SELECT 'b' BETWEEN 'a' AND 'c';
-> 1
mysql> SELECT 2 BETWEEN 2 AND '3';
-> 1
mysql> SELECT 2 BETWEEN 2 AND 'x-3';
-> 0
```

For best results when using *BETWEEN* with date or time values, use *CAST()* to explicitly convert the values to the desired data type. Examples: If you compare a *DATETIME* to two *DATE* values, convert the *DATE* values to *DATETIME* values. If you use a string constant such as '2001-1-1' in a comparison to a *DATE*, cast the string to a *DATE*.

- *expr NOT BETWEEN min AND max*

This is the same as *NOT (expr BETWEEN min AND max)*.

- *COALESCE(value,...)*

Returns the first non-`NULL` value in the list, or `NULL` if there are no non-`NULL` values.

The return type of `COALESCE ()` is the aggregated type of the argument types.

```
mysql> SELECT COALESCE(NULL,1);
-> 1
mysql> SELECT COALESCE(NULL,NULL,NULL);
-> NULL
```

- `GREATEST(value1,value2,...)`

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for `LEAST ()`.

```
mysql> SELECT GREATEST(2,0);
-> 2
mysql> SELECT GREATEST(34.0,3.0,5.0,767.0);
-> 767.0
mysql> SELECT GREATEST('B','A','C');
-> 'C'
```

`GREATEST ()` returns `NULL` if any argument is `NULL`.

- `expr IN (value,...)`

Returns `1` (true) if `expr` is equal to any of the values in the `IN ()` list, else returns `0` (false).

Type conversion takes place according to the rules described in [Section 12.3, “Type Conversion in Expression Evaluation”](#), applied to all the arguments. If no type conversion is needed for the values in the `IN ()` list, they are all non-`JSON` constants of the same type, and `expr` can be compared to each of them as a value of the same type (possibly after type conversion), an optimization takes place. The values the list are sorted and the search for `expr` is done using a binary search, which makes the `IN ()` operation very quick.

```
mysql> SELECT 2 IN (0,3,5,7);
-> 0
mysql> SELECT 'wefwf' IN ('wee','wefwf','weg');
-> 1
```

`IN ()` can be used to compare row constructors:

```
mysql> SELECT (3,4) IN ((1,2), (3,4));
-> 1
mysql> SELECT (3,4) IN ((1,2), (3,5));
-> 0
```

You should never mix quoted and unquoted values in an `IN ()` list because the comparison rules for quoted values (such as strings) and unquoted values (such as numbers) differ. Mixing types may therefore lead to inconsistent results. For example, do not write an `IN ()` expression like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN (1,2,'a');
```

Instead, write it like this:

```
SELECT val1 FROM tbl1 WHERE val1 IN ('1','2','a');
```

Implicit type conversion may produce nonintuitive results:

```
mysql> SELECT 'a' IN (0), 0 IN ('b');
```

```
-> 1, 1
```

In both cases, the comparison values are converted to floating-point values, yielding 0.0 in each case, and a comparison result of 1 (true).

The number of values in the `IN()` list is only limited by the `max_allowed_packet` value.

To comply with the SQL standard, `IN()` returns `NULL` not only if the expression on the left hand side is `NULL`, but also if no match is found in the list and one of the expressions in the list is `NULL`.

`IN()` syntax can also be used to write certain types of subqueries. See [Section 13.2.11.3, "Subqueries with ANY, IN, or SOME"](#).

- `expr NOT IN (value,...)`

This is the same as `NOT (expr IN (value,...))`.

- `INTERVAL(N,N1,N2,N3,...)`

Returns 0 if $N < N1$, 1 if $N < N2$ and so on or -1 if N is `NULL`. All arguments are treated as integers. It is required that $N1 < N2 < N3 < \dots < Nn$ for this function to work correctly. This is because a binary search is used (very fast).

```
mysql> SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
-> 3
mysql> SELECT INTERVAL(10, 1, 10, 100, 1000);
-> 2
mysql> SELECT INTERVAL(22, 23, 30, 44, 200);
-> 0
```

- `IS boolean_value`

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
-> 1, 1, 1
```

- `IS NOT boolean_value`

Tests a value against a boolean value, where `boolean_value` can be `TRUE`, `FALSE`, or `UNKNOWN`.

```
mysql> SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
-> 1, 1, 0
```

- `IS NULL`

Tests whether a value is `NULL`.

```
mysql> SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
-> 0, 0, 1
```

To work well with ODBC programs, MySQL supports the following extra features when using `IS NULL`:

- If `sql_auto_is_null` variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert,

see [Section 12.16, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison can be disabled by setting `sql_auto_is_null = 0`. See [Section 5.1.8, “Server System Variables”](#).

The default value of `sql_auto_is_null` is 0.

- For `DATE` and `DATETIME` columns that are declared as `NOT NULL`, you can find the special date '0000-00-00' by using a statement like this:

```
SELECT * FROM tbl_name WHERE date_column IS NULL
```

This is needed to get some ODBC applications to work because ODBC does not support a '0000-00-00' date value.

See [Obtaining Auto-Increment Values](#), and the description for the `FLAG_AUTO_IS_NULL` option at [Connector/ODBC Connection Parameters](#).

- `IS NOT NULL`

Tests whether a value is not `NULL`.

```
mysql> SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
-> 1, 1, 0
```

- `ISNULL(expr)`

If `expr` is `NULL`, `ISNULL()` returns 1, otherwise it returns 0.

```
mysql> SELECT ISNULL(1+1);
-> 0
mysql> SELECT ISNULL(1/0);
-> 1
```

`ISNULL()` can be used instead of `=` to test whether a value is `NULL`. (Comparing a value to `NULL` using `=` always yields `NULL`.)

The `ISNULL()` function shares some special behaviors with the `IS NULL` comparison operator. See the description of `IS NULL`.

- `LEAST(value1,value2,...)`

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If any argument is `NULL`, the result is `NULL`. No comparison is needed.
- If all arguments are integer-valued, they are compared as integers.
- If at least one argument is double precision, they are compared as double-precision values. Otherwise, if at least one argument is a `DECIMAL` value, they are compared as `DECIMAL` values.
- If the arguments comprise a mix of numbers and strings, they are compared as strings.
- If any argument is a nonbinary (character) string, the arguments are compared as nonbinary strings.
- In all other cases, the arguments are compared as binary strings.

The return type of `LEAST()` is the aggregated type of the comparison argument types.

```
mysql> SELECT LEAST(2,0);
-> 0
```

```
mysql> SELECT LEAST(34.0,3.0,5.0,767.0);
-> 3.0
mysql> SELECT LEAST('B','A','C');
-> 'A'
```

12.4.3 Logical Operators

Table 12.5 Logical Operators

Name	Description
AND, &&	Logical AND
NOT, !	Negates value
OR,	Logical OR
XOR	Logical XOR

In SQL, all logical operators evaluate to `TRUE`, `FALSE`, or `NULL` (`UNKNOWN`). In MySQL, these are implemented as 1 (`TRUE`), 0 (`FALSE`), and `NULL`. Most of this is common to different SQL database servers, although some servers may return any nonzero value for `TRUE`.

MySQL evaluates any nonzero, non-`NULL` value to `TRUE`. For example, the following statements all assess to `TRUE`:

```
mysql> SELECT 10 IS TRUE;
-> 1
mysql> SELECT -10 IS TRUE;
-> 1
mysql> SELECT 'string' IS NOT NULL;
-> 1
```

- `NOT, !`

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is nonzero, and `NOT NULL` returns `NULL`.

```
mysql> SELECT NOT 10;
-> 0
mysql> SELECT NOT 0;
-> 1
mysql> SELECT NOT NULL;
-> NULL
mysql> SELECT ! (1+1);
-> 0
mysql> SELECT ! 1+1;
-> 1
```

The last example produces 1 because the expression evaluates the same way as `(!1)+1`.

The `!` operator is a nonstandard MySQL extension. As of MySQL 8.0.17, this operator is deprecated and support for it will be removed in a future MySQL version. Applications should be adjusted to use the standard SQL `NOT` operator.

- `AND, &&`

Logical AND. Evaluates to 1 if all operands are nonzero and not `NULL`, to 0 if one or more operands are 0, otherwise `NULL` is returned.

```
mysql> SELECT 1 AND 1;
-> 1
mysql> SELECT 1 AND 0;
-> 0
mysql> SELECT 1 AND NULL;
-> NULL
mysql> SELECT 0 AND NULL;
-> 0
mysql> SELECT NULL AND 0;
-> 0
```

The `&&` operator is a nonstandard MySQL extension. As of MySQL 8.0.17, this operator is deprecated and support for it will be removed in a future MySQL version. Applications should be adjusted to use the standard SQL `AND` operator.

- `OR, ||`

Logical OR. When both operands are non-`NULL`, the result is `1` if any operand is nonzero, and `0` otherwise. With a `NULL` operand, the result is `1` if the other operand is nonzero, and `NULL` otherwise. If both operands are `NULL`, the result is `NULL`.

```
mysql> SELECT 1 OR 1;
-> 1
mysql> SELECT 1 OR 0;
-> 1
mysql> SELECT 0 OR 0;
-> 0
mysql> SELECT 0 OR NULL;
-> NULL
mysql> SELECT 1 OR NULL;
-> 1
```

Note

If the `PIPES_AS_CONCAT` SQL mode is enabled, `||` signifies the SQL-standard string concatenation operator (like `CONCAT()`).

The `||` operator is a nonstandard MySQL extension. As of MySQL 8.0.17, this operator is deprecated and support for it will be removed in a future MySQL version. Applications should be adjusted to use the standard SQL `OR` operator. Exception: Deprecation does not apply if `PIPES_AS_CONCAT` is enabled because, in that case, `||` signifies string concatenation.

- `XOR`

Logical XOR. Returns `NULL` if either operand is `NULL`. For non-`NULL` operands, evaluates to `1` if an odd number of operands is nonzero, otherwise `0` is returned.

```
mysql> SELECT 1 XOR 1;
-> 0
mysql> SELECT 1 XOR 0;
-> 1
mysql> SELECT 1 XOR NULL;
-> NULL
mysql> SELECT 1 XOR 1 XOR 1;
-> 1
```

$a \text{ XOR } b$ is mathematically equal to $(a \text{ AND } (\text{NOT } b)) \text{ OR } ((\text{NOT } a) \text{ AND } b)$.

12.4.4 Assignment Operators

Table 12.6 Assignment Operators

Name	Description
<code>:=</code>	Assign a value
<code>=</code>	Assign a value (as part of a <code>SET</code> statement, or as part of the <code>SET</code> clause in an <code>UPDATE</code> statement)

- `:=`

Assignment operator. Causes the user variable on the left hand side of the operator to take on the value to its right. The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement. You can perform multiple assignments in the same statement.

Unlike `=`, the `:=` operator is never interpreted as a comparison operator. This means you can use `:=` in any valid SQL statement (not just in `SET` statements) to assign a value to a variable.

```
mysql> SELECT @var1, @var2;
      -> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
      -> 1, NULL
mysql> SELECT @var1, @var2;
      -> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
      -> 1, 1
mysql> SELECT @var1, @var2;
      -> 1, 1

mysql> SELECT @var1:=COUNT(*) FROM t1;
      -> 4
mysql> SELECT @var1;
      -> 4
```

You can make value assignments using `:=` in other statements besides `SELECT`, such as `UPDATE`, as shown here:

```
mysql> SELECT @var1;
      -> 4
mysql> SELECT * FROM t1;
      -> 1, 3, 5, 7

mysql> UPDATE t1 SET c1 = 2 WHERE c1 = @var1:= 1;
Query OK, 1 row affected (0.00 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT @var1;
      -> 1
mysql> SELECT * FROM t1;
      -> 2, 3, 5, 7
```

While it is also possible both to set and to read the value of the same variable in a single SQL statement using the `:=` operator, this is not recommended. [Section 9.4, “User-Defined Variables”](#), explains why you should avoid doing this.

- `=`

This operator is used to perform value assignments in two cases, described in the next two paragraphs.

Within a `SET` statement, `=` is treated as an assignment operator that causes the user variable on the left hand side of the operator to take on the value to its right. (In other words, when used in a `SET` statement, `=` is treated identically to `:=`.) The value on the right hand side may be a literal value, another variable storing a value, or any legal expression that yields a scalar value, including the result of a query (provided that this value is a scalar value). You can perform multiple assignments in the same `SET` statement.

In the `SET` clause of an `UPDATE` statement, `=` also acts as an assignment operator; in this case, however, it causes the column named on the left hand side of the operator to assume the value given to the right, provided any `WHERE` conditions that are part of the `UPDATE` are met. You can make multiple assignments in the same `SET` clause of an `UPDATE` statement.

In any other context, `=` is treated as a [comparison operator](#).

```
mysql> SELECT @var1, @var2;
      -> NULL, NULL
mysql> SELECT @var1 := 1, @var2;
      -> 1, NULL
mysql> SELECT @var1, @var2;
      -> 1, NULL
mysql> SELECT @var1, @var2 := @var1;
```

```

-> 1, 1
mysql> SELECT @var1, @var2;
-> 1, 1

```

For more information, see [Section 13.7.6.1, “SET Syntax for Variable Assignment”](#), [Section 13.2.13, “UPDATE Statement”](#), and [Section 13.2.11, “Subqueries”](#).

12.5 Flow Control Functions

Table 12.7 Flow Control Operators

Name	Description
<code>CASE</code>	Case operator
<code>IF()</code>	If/else construct
<code>IFNULL()</code>	Null if/else construct
<code>NULLIF()</code>	Return NULL if <code>expr1 = expr2</code>

- `CASE value WHEN compare_value THEN result [WHEN compare_value THEN result ...] [ELSE result] END`

```
CASE WHEN condition THEN result [WHEN condition THEN result ...] [ELSE result] END
```

The first `CASE` syntax returns the *result* for the first *value=compare_value* comparison that is true. The second syntax returns the result for the first condition that is true. If no comparison or condition is true, the result after `ELSE` is returned, or `NULL` if there is no `ELSE` part.

Note

The syntax of the `CASE expr` described here differs slightly from that of the SQL `CASE statement` described in [Section 13.6.5.1, “CASE Statement”](#), for use inside stored programs. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

The return type of a `CASE` expression result is the aggregated type of all result values:

- If all types are numeric, the aggregated type is also numeric:
 - If at least one argument is double precision, the result is double precision.
 - Otherwise, if at least one argument is `DECIMAL`, the result is `DECIMAL`.
 - Otherwise, the result is an integer type (with one exception):
 - If all integer types are all signed or all unsigned, the result is the same sign and the precision is the highest of all specified integer types (that is, `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, or `BIGINT`).
 - If there is a combination of signed and unsigned integer types, the result is signed and the precision may be higher. For example, if the types are signed `INT` and unsigned `INT`, the result is signed `BIGINT`.
 - The exception is unsigned `BIGINT` combined with any signed integer type. The result is `DECIMAL` with sufficient precision and scale 0.
- If all types are `BIT`, the result is `BIT`. Otherwise, `BIT` arguments are treated similar to `BIGINT`.
- If all types are `YEAR`, the result is `YEAR`. Otherwise, `YEAR` arguments are treated similar to `INT`.

- If all types are character string ([CHAR](#) or [VARCHAR](#)), the result is [VARCHAR](#) with maximum length determined by the longest character length of the operands.
- If all types are character or binary string, the result is [VARBINARY](#).
- [SET](#) and [ENUM](#) are treated similar to [VARCHAR](#); the result is [VARCHAR](#).
- If all types are [JSON](#), the result is [JSON](#).
- If all types are temporal, the result is temporal:
 - If all temporal types are [DATE](#), [TIME](#), or [TIMESTAMP](#), the result is [DATE](#), [TIME](#), or [TIMESTAMP](#), respectively.
 - Otherwise, for a mix of temporal types, the result is [DATETIME](#).
- If all types are [GEOMETRY](#), the result is [GEOMETRY](#).
- If any type is [BLOB](#), the result is [BLOB](#).
- For all other type combinations, the result is [VARCHAR](#).
- Literal [NULL](#) operands are ignored for type aggregation.

```
mysql> SELECT CASE 1 WHEN 1 THEN 'one'
->      WHEN 2 THEN 'two' ELSE 'more' END;
-> 'one'
mysql> SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
-> 'true'
mysql> SELECT CASE BINARY 'B'
->      WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
-> NULL
```

- [IF\(expr1,expr2,expr3\)](#)

If [expr1](#) is [TRUE](#) ([expr1](#) <> 0 and [expr1](#) <> [NULL](#)), [IF\(\)](#) returns [expr2](#). Otherwise, it returns [expr3](#).

Note

There is also an [IF statement](#), which differs from the [IF\(\)](#) function described here. See [Section 13.6.5.2, “IF Statement”](#).

If only one of [expr2](#) or [expr3](#) is explicitly [NULL](#), the result type of the [IF\(\)](#) function is the type of the non-[NULL](#) expression.

The default return type of [IF\(\)](#) (which may matter when it is stored into a temporary table) is calculated as follows:

- If [expr2](#) or [expr3](#) produce a string, the result is a string.

If [expr2](#) and [expr3](#) are both strings, the result is case-sensitive if either string is case sensitive.
- If [expr2](#) or [expr3](#) produce a floating-point value, the result is a floating-point value.
- If [expr2](#) or [expr3](#) produce an integer, the result is an integer.

```
mysql> SELECT IF(1>2,2,3);
-> 3
mysql> SELECT IF(1<2,'yes','no');
-> 'yes'
mysql> SELECT IF(STRCMP('test','test1'),'no','yes');
-> 'no'
```

- `IFNULL(expr1,expr2)`

If `expr1` is not `NULL`, `IFNULL()` returns `expr1`; otherwise it returns `expr2`.

```
mysql> SELECT IFNULL(1,0);
-> 1
mysql> SELECT IFNULL(NULL,10);
-> 10
mysql> SELECT IFNULL(1/0,10);
-> 10
mysql> SELECT IFNULL(1/0,'yes');
-> 'yes'
```

The default return type of `IFNULL(expr1,expr2)` is the more “general” of the two expressions, in the order `STRING`, `REAL`, or `INTEGER`. Consider the case of a table based on expressions or where MySQL must internally store a value returned by `IFNULL()` in a temporary table:

```
mysql> CREATE TABLE tmp SELECT IFNULL(1,'test') AS test;
mysql> DESCRIBE tmp;
+-----+-----+-----+-----+-----+-----+
| Field | Type          | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| test  | varbinary(4)  | NO   |     |         |       |
+-----+-----+-----+-----+-----+-----+
```

In this example, the type of the `test` column is `VARBINARY(4)` (a string type).

- `NULLIF(expr1,expr2)`

Returns `NULL` if `expr1 = expr2` is true, otherwise returns `expr1`. This is the same as `CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END`.

The return value has the same type as the first argument.

```
mysql> SELECT NULLIF(1,1);
-> NULL
mysql> SELECT NULLIF(1,2);
-> 1
```

Note

MySQL evaluates `expr1` twice if the arguments are not equal.

12.6 Numeric Functions and Operators

Table 12.8 Numeric Functions and Operators

Name	Description
<code>%, MOD</code>	Modulo operator
<code>*</code>	Multiplication operator
<code>+</code>	Addition operator
<code>-</code>	Minus operator
<code>-</code>	Change the sign of the argument
<code>/</code>	Division operator
<code>ABS()</code>	Return the absolute value
<code>ACOS()</code>	Return the arc cosine
<code>ASIN()</code>	Return the arc sine
<code>ATAN()</code>	Return the arc tangent

Name	Description
ATAN2 () , ATAN ()	Return the arc tangent of the two arguments
CEIL ()	Return the smallest integer value not less than the argument
CEILING ()	Return the smallest integer value not less than the argument
CONV ()	Convert numbers between different number bases
COS ()	Return the cosine
COT ()	Return the cotangent
CRC32 ()	Compute a cyclic redundancy check value
DEGREES ()	Convert radians to degrees
DIV	Integer division
EXP ()	Raise to the power of
FLOOR ()	Return the largest integer value not greater than the argument
LN ()	Return the natural logarithm of the argument
LOG ()	Return the natural logarithm of the first argument
LOG10 ()	Return the base-10 logarithm of the argument
LOG2 ()	Return the base-2 logarithm of the argument
MOD ()	Return the remainder
PI ()	Return the value of pi
POW ()	Return the argument raised to the specified power
POWER ()	Return the argument raised to the specified power
RADIANS ()	Return argument converted to radians
RAND ()	Return a random floating-point value
ROUND ()	Round the argument
SIGN ()	Return the sign of the argument
SIN ()	Return the sine of the argument
SQRT ()	Return the square root of the argument
TAN ()	Return the tangent of the argument
TRUNCATE ()	Truncate to specified number of decimal places

12.6.1 Arithmetic Operators

Table 12.9 Arithmetic Operators

Name	Description
% , MOD	Modulo operator
*	Multiplication operator
+	Addition operator
-	Minus operator
-	Change the sign of the argument
/	Division operator
DIV	Integer division

The usual arithmetic operators are available. The result is determined according to the following rules:

- In the case of `-`, `+`, and `*`, the result is calculated with `BIGINT` (64-bit) precision if both operands are integers.
- If both operands are integers and any of them are unsigned, the result is an unsigned integer. For subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is signed even if any operand is unsigned.
- If any of the operands of a `+`, `-`, `/`, `*`, `%` is a real or string value, the precision of the result is the precision of the operand with the maximum precision.
- In division performed with `/`, the scale of the result when using two exact-value operands is the scale of the first operand plus the value of the `div_precision_increment` system variable (which is 4 by default). For example, the result of the expression `5.05 / 0.014` has a scale of six decimal places (`360.714286`).

These rules are applied for each operation, such that nested calculations imply the precision of each component. Hence, `(14620 / 9432456) / (24250 / 9432456)`, resolves first to `(0.0014) / (0.0026)`, with the final result having 8 decimal places (`0.60288653`).

Because of these rules and the way they are applied, care should be taken to ensure that components and subcomponents of a calculation use the appropriate level of precision. See [Section 12.11, “Cast Functions and Operators”](#).

For information about handling of overflow in numeric expression evaluation, see [Section 11.1.7, “Out-of-Range and Overflow Handling”](#).

Arithmetic operators apply to numbers. For other types of values, alternative operations may be available. For example, to add date values, use `DATE_ADD()`; see [Section 12.7, “Date and Time Functions”](#).

- `+`

Addition:

```
mysql> SELECT 3+5;
-> 8
```

- `-`

Subtraction:

```
mysql> SELECT 3-5;
-> -2
```

- `-`

Unary minus. This operator changes the sign of the operand.

```
mysql> SELECT - 2;
-> -2
```

**Note**

If this operator is used with a `BIGINT`, the return value is also a `BIGINT`. This means that you should avoid using `-` on integers that may have the value of -2^{63} .

- `*`

Multiplication:

```
mysql> SELECT 3*5;
-> 15
mysql> SELECT 18014398509481984*18014398509481984.0;
-> 324518553658426726783156020576256.0
```

```
mysql> SELECT 18014398509481984*18014398509481984;
      -> out-of-range error
```

The last expression produces an error because the result of the integer multiplication exceeds the 64-bit range of `BIGINT` calculations. (See [Section 11.1, “Numeric Data Types”](#).)

- /

Division:

```
mysql> SELECT 3/5;
      -> 0.60
```

Division by zero produces a `NULL` result:

```
mysql> SELECT 102/(1-1);
      -> NULL
```

A division is calculated with `BIGINT` arithmetic only if performed in a context where its result is converted to an integer.

- DIV

Integer division. Discards from the division result any fractional part to the right of the decimal point.

If either operand has a noninteger type, the operands are converted to `DECIMAL` and divided using `DECIMAL` arithmetic before converting the result to `BIGINT`. If the result exceeds `BIGINT` range, an error occurs.

```
mysql> SELECT 5 DIV 2, -5 DIV 2, 5 DIV -2, -5 DIV -2;
      -> 2, -2, -2, 2
```

- $N \% M, N \text{ MOD } M$

Modulo operation. Returns the remainder of N divided by M . For more information, see the description for the `MOD()` function in [Section 12.6.2, “Mathematical Functions”](#).

12.6.2 Mathematical Functions

Table 12.10 Mathematical Functions

Name	Description
<code>ABS()</code>	Return the absolute value
<code>ACOS()</code>	Return the arc cosine
<code>ASIN()</code>	Return the arc sine
<code>ATAN()</code>	Return the arc tangent
<code>ATAN2(), ATAN()</code>	Return the arc tangent of the two arguments
<code>CEIL()</code>	Return the smallest integer value not less than the argument
<code>CEILING()</code>	Return the smallest integer value not less than the argument
<code>CONV()</code>	Convert numbers between different number bases
<code>COS()</code>	Return the cosine
<code>COT()</code>	Return the cotangent
<code>CRC32()</code>	Compute a cyclic redundancy check value
<code>DEGREES()</code>	Convert radians to degrees
<code>EXP()</code>	Raise to the power of
<code>FLOOR()</code>	Return the largest integer value not greater than the argument

Name	Description
LN()	Return the natural logarithm of the argument
LOG()	Return the natural logarithm of the first argument
LOG10()	Return the base-10 logarithm of the argument
LOG2()	Return the base-2 logarithm of the argument
MOD()	Return the remainder
PI()	Return the value of pi
POW()	Return the argument raised to the specified power
POWER()	Return the argument raised to the specified power
RADIANS()	Return argument converted to radians
RAND()	Return a random floating-point value
ROUND()	Round the argument
SIGN()	Return the sign of the argument
SIN()	Return the sine of the argument
SQRT()	Return the square root of the argument
TAN()	Return the tangent of the argument
TRUNCATE()	Truncate to specified number of decimal places

All mathematical functions return [NULL](#) in the event of an error.

- [ABS\(X\)](#)

Returns the absolute value of *X*.

```
mysql> SELECT ABS(2);
-> 2
mysql> SELECT ABS(-32);
-> 32
```

This function is safe to use with [BIGINT](#) values.

- [ACOS\(X\)](#)

Returns the arc cosine of *X*, that is, the value whose cosine is *X*. Returns [NULL](#) if *X* is not in the range **-1 to 1**.

```
mysql> SELECT ACOS(1);
-> 0
mysql> SELECT ACOS(1.0001);
-> NULL
mysql> SELECT ACOS(0);
-> 1.5707963267949
```

- [ASIN\(X\)](#)

Returns the arc sine of *X*, that is, the value whose sine is *X*. Returns [NULL](#) if *X* is not in the range **-1 to 1**.

```
mysql> SELECT ASIN(0.2);
-> 0.20135792079033
mysql> SELECT ASIN('foo');

+-----+
| ASIN('foo') |
+-----+
|          0 |
+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+-----+-----+-----+
```

- **ATAN(*X*)**

Returns the arc tangent of *X*, that is, the value whose tangent is *X*.

```
mysql> SELECT ATAN(2);
-> 1.1071487177941
mysql> SELECT ATAN(-2);
-> -1.1071487177941
```

- **ATAN(*Y*,*X*), ATAN2(*Y*,*X*)**

Returns the arc tangent of the two variables *X* and *Y*. It is similar to calculating the arc tangent of *Y* / *X*, except that the signs of both arguments are used to determine the quadrant of the result.

```
mysql> SELECT ATAN(-2,2);
-> -0.78539816339745
mysql> SELECT ATAN2(PI(),0);
-> 1.5707963267949
```

- **CEIL(*X*)**

CEIL() is a synonym for **CEILING()**.

- **CEILING(*X*)**

Returns the smallest integer value not less than *X*.

```
mysql> SELECT CEILING(1.23);
-> 2
mysql> SELECT CEILING(-1.23);
-> -1
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- **CONV(*N*,*from_base*,*to_base*)**

Converts numbers between different number bases. Returns a string representation of the number *N*, converted from base *from_base* to base *to_base*. Returns **NULL** if any argument is **NULL**. The argument *N* is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If *from_base* is a negative number, *N* is regarded as a signed number. Otherwise, *N* is treated as unsigned. **CONV()** works with 64-bit precision.

```
mysql> SELECT CONV('a',16,2);
-> '1010'
mysql> SELECT CONV('6E',18,8);
-> '172'
mysql> SELECT CONV(-17,10,-18);
-> '-H'
mysql> SELECT CONV(10+'10'+ '10'+X'0a',10,10);
-> '40'
```

- **COS(*X*)**

Returns the cosine of *X*, where *X* is given in radians.

```
mysql> SELECT COS(PI());
-> -1
```

- **COT(*X*)**

Returns the cotangent of X .

```
mysql> SELECT COT(12);
-> -1.5726734063977
mysql> SELECT COT(0);
-> out-of-range error
```

- `CRC32(expr)`

Computes a cyclic redundancy check value and returns a 32-bit unsigned value. The result is `NULL` if the argument is `NULL`. The argument is expected to be a string and (if possible) is treated as one if it is not.

```
mysql> SELECT CRC32('MySQL');
-> 3259397556
mysql> SELECT CRC32('mysql');
-> 2501908538
```

- `DEGREES(X)`

Returns the argument X , converted from radians to degrees.

```
mysql> SELECT DEGREES(PI());
-> 180
mysql> SELECT DEGREES(PI() / 2);
-> 90
```

- `EXP(X)`

Returns the value of e (the base of natural logarithms) raised to the power of X . The inverse of this function is `LOG()` (using a single argument only) or `LN()`.

```
mysql> SELECT EXP(2);
-> 7.3890560989307
mysql> SELECT EXP(-2);
-> 0.13533528323661
mysql> SELECT EXP(0);
-> 1
```

- `FLOOR(X)`

Returns the largest integer value not greater than X .

```
mysql> SELECT FLOOR(1.23), FLOOR(-1.23);
-> 1, -2
```

For exact-value numeric arguments, the return value has an exact-value numeric type. For string or floating-point arguments, the return value has a floating-point type.

- `FORMAT(X,D)`

Formats the number X to a format like ' $\#,###,###.\#\#$ ', rounded to D decimal places, and returns the result as a string. For details, see [Section 12.8, "String Functions and Operators"](#).

- `HEX(N_or_S)`

This function can be used to obtain a hexadecimal representation of a decimal number or a string; the manner in which it does so varies according to the argument's type. See this function's description in [Section 12.8, "String Functions and Operators"](#), for details.

- `LN(X)`

Returns the natural logarithm of X ; that is, the base- e logarithm of X . If X is less than or equal to `0.0E0`, the function returns `NULL` and a warning "Invalid argument for logarithm" is reported.

```
mysql> SELECT LN(2);
```

```
mysql> SELECT LN(-2);
-> NULL
```

This function is synonymous with `LOG(X)`. The inverse of this function is the `EXP()` function.

- `LOG(X)`, `LOG(B,X)`

If called with one parameter, this function returns the natural logarithm of `X`. If `X` is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

The inverse of this function (when called with a single argument) is the `EXP()` function.

```
mysql> SELECT LOG(2);
-> 0.69314718055995
mysql> SELECT LOG(-2);
-> NULL
```

If called with two parameters, this function returns the logarithm of `X` to the base `B`. If `X` is less than or equal to 0, or if `B` is less than or equal to 1, then `NULL` is returned.

```
mysql> SELECT LOG(2,65536);
-> 16
mysql> SELECT LOG(10,100);
-> 2
mysql> SELECT LOG(1,100);
-> NULL
```

`LOG(B,X)` is equivalent to `LOG(X) / LOG(B)`.

- `LOG2(X)`

Returns the base-2 logarithm of `X`. If `X` is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

```
mysql> SELECT LOG2(65536);
-> 16
mysql> SELECT LOG2(-100);
-> NULL
```

`LOG2()` is useful for finding out how many bits a number requires for storage. This function is equivalent to the expression `LOG(X) / LOG(2)`.

- `LOG10(X)`

Returns the base-10 logarithm of `X`. If `X` is less than or equal to 0.0E0, the function returns `NULL` and a warning “Invalid argument for logarithm” is reported.

```
mysql> SELECT LOG10(2);
-> 0.30102999566398
mysql> SELECT LOG10(100);
-> 2
mysql> SELECT LOG10(-100);
-> NULL
```

`LOG10(X)` is equivalent to `LOG(10,X)`.

- `MOD(N,M)`, `N % M`, `N MOD M`

Modulo operation. Returns the remainder of `N` divided by `M`.

```
mysql> SELECT MOD(234, 10);
-> 4
mysql> SELECT 253 % 7;
-> 1
mysql> SELECT MOD(29,9);
-> 2
```

```
mysql> SELECT 29 MOD 9;
-> 2
```

This function is safe to use with `BIGINT` values.

`MOD()` also works on values that have a fractional part and returns the exact remainder after division:

```
mysql> SELECT MOD(34.5,3);
-> 1.5
```

`MOD(N, 0)` returns `NULL`.

- `PI()`

Returns the value of π (pi). The default number of decimal places displayed is seven, but MySQL uses the full double-precision value internally.

```
mysql> SELECT PI();
-> 3.141593
mysql> SELECT PI()+0.00000000000000000000;
-> 3.141592653589793116
```

- `POW(X, Y)`

Returns the value of `X` raised to the power of `Y`.

```
mysql> SELECT POW(2,2);
-> 4
mysql> SELECT POW(2,-2);
-> 0.25
```

- `POWER(X, Y)`

This is a synonym for `POW()`.

- `RADIANS(X)`

Returns the argument `X`, converted from degrees to radians. (Note that π radians equals 180 degrees.)

```
mysql> SELECT RADIANS(90);
-> 1.5707963267949
```

- `RAND([N])`

Returns a random floating-point value `v` in the range $0 \leq v < 1.0$. To obtain a random integer `R` in the range $i \leq R < j$, use the expression `FLOOR(i + RAND() * (j - i))`. For example, to obtain a random integer in the range the range $7 \leq R < 12$, use the following statement:

```
SELECT FLOOR(7 + (RAND() * 5));
```

If an integer argument `N` is specified, it is used as the seed value:

- With a constant initializer argument, the seed is initialized once when the statement is prepared, prior to execution.
- With a nonconstant initializer argument (such as a column name), the seed is initialized with the value for each invocation of `RAND()`.

One implication of this behavior is that for equal argument values, `RAND(N)` returns the same value each time, and thus produces a repeatable sequence of column values. In the following example, the sequence of values produced by `RAND(3)` is the same both places it occurs.

```
mysql> CREATE TABLE t (i INT);
```

```
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i    | RAND()                |
+-----+-----+
| 1    | 0.61914388706828      |
| 2    | 0.93845168309142      |
| 3    | 0.83482678498591      |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i    | RAND(3)                |
+-----+-----+
| 1    | 0.90576975597606      |
| 2    | 0.37307905813035      |
| 3    | 0.14808605345719      |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND() FROM t;
+-----+-----+
| i    | RAND()                |
+-----+-----+
| 1    | 0.35877890638893      |
| 2    | 0.28941420772058      |
| 3    | 0.37073435016976      |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT i, RAND(3) FROM t;
+-----+-----+
| i    | RAND(3)                |
+-----+-----+
| 1    | 0.90576975597606      |
| 2    | 0.37307905813035      |
| 3    | 0.14808605345719      |
+-----+-----+
3 rows in set (0.01 sec)
```

`RAND()` in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join). Thus, for optimizer purposes, `RAND()` is not a constant value and cannot be used for index optimizations. For more information, see [Section 8.2.1.20, “Function Call Optimization”](#).

Use of a column with `RAND()` values in an `ORDER BY` or `GROUP BY` clause may yield unexpected results because for either clause a `RAND()` expression can be evaluated multiple times for the same row, each time returning a different result. If the goal is to retrieve rows in random order, you can use a statement like this:

```
SELECT * FROM tbl_name ORDER BY RAND();
```

To select a random sample from a set of rows, combine `ORDER BY RAND()` with `LIMIT`:

```
SELECT * FROM table1, table2 WHERE a=b AND c<d ORDER BY RAND() LIMIT 1000;
```

`RAND()` is not meant to be a perfect random generator. It is a fast way to generate random numbers on demand that is portable between platforms for the same MySQL version.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `ROUND(X)`, `ROUND(X,D)`

Rounds the argument *X* to *D* decimal places. The rounding algorithm depends on the data type of *X*. *D* defaults to 0 if not specified. *D* can be negative to cause *D* digits left of the decimal point of the value *X* to become zero. The maximum absolute value for *D* is 30; any digits in excess of 30 (or -30) are truncated.

```
mysql> SELECT ROUND(-1.23);
-> -1
mysql> SELECT ROUND(-1.58);
-> -2
mysql> SELECT ROUND(1.58);
-> 2
mysql> SELECT ROUND(1.298, 1);
-> 1.3
mysql> SELECT ROUND(1.298, 0);
-> 1
mysql> SELECT ROUND(23.298, -1);
-> 20
mysql> SELECT ROUND(.12345678901234567890123456789012345, 35);
-> 0.123456789012345678901234567890
```

The return value has the same type as the first argument (assuming that it is integer, double, or decimal). This means that for an integer argument, the result is an integer (no decimal places):

```
mysql> SELECT ROUND(150.000,2), ROUND(150,2);
+-----+-----+
| ROUND(150.000,2) | ROUND(150,2) |
+-----+-----+
| 150.00 | 150 |
+-----+-----+
```

`ROUND()` uses the following rules depending on the type of the first argument:

- For exact-value numbers, `ROUND()` uses the “round half away from zero” or “round toward nearest” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly halfway between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3 | 2 |
+-----+-----+
```

For more information, see [Section 12.25, “Precision Math”](#).

In MySQL 8.0.21 and later, the data type returned by `ROUND()` (and `TRUNCATE()`) is determined according to the rules listed here:

- When the first argument is of any integer type, the return type is always `BIGINT`.
- When the first argument is of any floating-point type or of any non-numeric type, the return type is always `DOUBLE`.
- When the first argument is a `DECIMAL` value, the return type is also `DECIMAL`.

- The type attributes for the return value are also copied from the first argument, except in the case of `DECIMAL`, when the second argument is a constant value.

When the desired number of decimal places is less than the scale of the argument, the scale and the precision of the result are adjusted accordingly.

In addition, for `ROUND()` (but not for the `TRUNCATE()` function), the precision is extended by one place to accommodate rounding that increases the number of significant digits. If the second argument is negative, the return type is adjusted such that its scale is 0, with a corresponding precision. For example, `ROUND(99.999, 2)` returns `100.00`—the first argument is `DECIMAL(5, 3)`, and the return type is `DECIMAL(5, 2)`.

If the second argument is negative, the return type has scale 0 and a corresponding precision; `ROUND(99.999, -1)` returns `100`, which is `DECIMAL(3, 0)`.

- `SIGN(X)`

Returns the sign of the argument as `-1`, `0`, or `1`, depending on whether `X` is negative, zero, or positive.

```
mysql> SELECT SIGN(-32);
      -> -1
mysql> SELECT SIGN(0);
      -> 0
mysql> SELECT SIGN(234);
      -> 1
```

- `SIN(X)`

Returns the sine of `X`, where `X` is given in radians.

```
mysql> SELECT SIN(PI());
      -> 1.2246063538224e-16
mysql> SELECT ROUND(SIN(PI()));
      -> 0
```

- `SQRT(X)`

Returns the square root of a nonnegative number `X`.

```
mysql> SELECT SQRT(4);
      -> 2
mysql> SELECT SQRT(20);
      -> 4.4721359549996
mysql> SELECT SQRT(-16);
      -> NULL
```

- `TAN(X)`

Returns the tangent of `X`, where `X` is given in radians.

```
mysql> SELECT TAN(PI());
      -> -1.2246063538224e-16
mysql> SELECT TAN(PI()+1);
      -> 1.5574077246549
```

- `TRUNCATE(X, D)`

Returns the number `X`, truncated to `D` decimal places. If `D` is `0`, the result has no decimal point or fractional part. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero.

```
mysql> SELECT TRUNCATE(1.223,1);
      -> 1.2
mysql> SELECT TRUNCATE(1.999,1);
      -> 1.9
```

```
mysql> SELECT TRUNCATE(1.999,0);
-> 1
mysql> SELECT TRUNCATE(-1.999,1);
-> -1.9
mysql> SELECT TRUNCATE(122,-2);
-> 100
mysql> SELECT TRUNCATE(10.28*100,0);
-> 1028
```

All numbers are rounded toward zero.

In MySQL 8.0.21 and later, the data type returned by `TRUNCATE ()` follows the same rules that determine the return type of the `ROUND ()` function; for details, see the description for `ROUND ()`.

12.7 Date and Time Functions

This section describes the functions that can be used to manipulate temporal values. See [Section 11.2, “Date and Time Data Types”](#), for a description of the range of values each date and time type has and the valid formats in which values may be specified.

Table 12.11 Date and Time Functions

Name	Description
<code>ADDDATE ()</code>	Add time values (intervals) to a date value
<code>ADDTIME ()</code>	Add time
<code>CONVERT_TZ ()</code>	Convert from one time zone to another
<code>CURDATE ()</code>	Return the current date
<code>CURRENT_DATE ()</code> , <code>CURRENT_DATE</code>	Synonyms for <code>CURDATE()</code>
<code>CURRENT_TIME ()</code> , <code>CURRENT_TIME</code>	Synonyms for <code>CURTIME()</code>
<code>CURRENT_TIMESTAMP ()</code> , <code>CURRENT_TIMESTAMP</code>	Synonyms for <code>NOW()</code>
<code>CURTIME ()</code>	Return the current time
<code>DATE ()</code>	Extract the date part of a date or datetime expression
<code>DATE_ADD ()</code>	Add time values (intervals) to a date value
<code>DATE_FORMAT ()</code>	Format date as specified
<code>DATE_SUB ()</code>	Subtract a time value (interval) from a date
<code>DATEDIFF ()</code>	Subtract two dates
<code>DAY ()</code>	Synonym for <code>DAYOFMONTH()</code>
<code>DAYNAME ()</code>	Return the name of the weekday
<code>DAYOFMONTH ()</code>	Return the day of the month (0-31)
<code>DAYOFWEEK ()</code>	Return the weekday index of the argument
<code>DAYOFYEAR ()</code>	Return the day of the year (1-366)
<code>EXTRACT ()</code>	Extract part of a date
<code>FROM_DAYS ()</code>	Convert a day number to a date
<code>FROM_UNIXTIME ()</code>	Format Unix timestamp as a date
<code>GET_FORMAT ()</code>	Return a date format string
<code>HOUR ()</code>	Extract the hour
<code>LAST_DAY</code>	Return the last day of the month for the argument
<code>LOCALTIME ()</code> , <code>LOCALTIME</code>	Synonym for <code>NOW()</code>
<code>LOCALTIMESTAMP</code> , <code>LOCALTIMESTAMP ()</code>	Synonym for <code>NOW()</code>

Name	Description
MAKEDATE ()	Create a date from the year and day of year
MAKETIME ()	Create time from hour, minute, second
MICROSECOND ()	Return the microseconds from argument
MINUTE ()	Return the minute from the argument
MONTH ()	Return the month from the date passed
MONTHNAME ()	Return the name of the month
NOW ()	Return the current date and time
PERIOD_ADD ()	Add a period to a year-month
PERIOD_DIFF ()	Return the number of months between periods
QUARTER ()	Return the quarter from a date argument
SEC_TO_TIME ()	Converts seconds to 'hh:mm:ss' format
SECOND ()	Return the second (0-59)
STR_TO_DATE ()	Convert a string to a date
SUBDATE ()	Synonym for DATE_SUB() when invoked with three arguments
SUBTIME ()	Subtract times
SYSDATE ()	Return the time at which the function executes
TIME ()	Extract the time portion of the expression passed
TIME_FORMAT ()	Format as time
TIME_TO_SEC ()	Return the argument converted to seconds
TIMEDIFF ()	Subtract time
TIMESTAMP ()	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
TIMESTAMPADD ()	Add an interval to a datetime expression
TIMESTAMPDIFF ()	Subtract an interval from a datetime expression
TO_DAYS ()	Return the date argument converted to days
TO_SECONDS ()	Return the date or datetime argument converted to seconds since Year 0
UNIX_TIMESTAMP ()	Return a Unix timestamp
UTC_DATE ()	Return the current UTC date
UTC_TIME ()	Return the current UTC time
UTC_TIMESTAMP ()	Return the current UTC date and time
WEEK ()	Return the week number
WEEKDAY ()	Return the weekday index
WEEKOFYEAR ()	Return the calendar week of the date (1-53)
YEAR ()	Return the year
YEARWEEK ()	Return the year and week

Here is an example that uses date functions. The following query selects all rows with a `date_col` value from within the last 30 days:

```
mysql> SELECT something FROM tbl_name
-> WHERE DATE_SUB(CURDATE(),INTERVAL 30 DAY) <= date_col;
```

The query also selects rows with dates that lie in the future.

Functions that expect date values usually accept datetime values and ignore the time part. Functions that expect time values usually accept datetime values and ignore the date part.

Functions that return the current date or time each are evaluated only once per query at the start of query execution. This means that multiple references to a function such as `NOW()` within a single query always produce the same result. (For our purposes, a single query also includes a call to a stored program (stored routine, trigger, or event) and all subprograms called by that program.) This principle also applies to `CURDATE()`, `CURTIME()`, `UTC_DATE()`, `UTC_TIME()`, `UTC_TIMESTAMP()`, and to any of their synonyms.

The `CURRENT_TIMESTAMP()`, `CURRENT_TIME()`, `CURRENT_DATE()`, and `FROM_UNIXTIME()` functions return values in the current session time zone, which is available as the session value of the `time_zone` system variable. In addition, `UNIX_TIMESTAMP()` assumes that its argument is a datetime value in the session time zone. See [Section 5.1.14, “MySQL Server Time Zone Support”](#).

Some date functions can be used with “zero” dates or incomplete dates such as `'2001-11-00'`, whereas others cannot. Functions that extract parts of dates typically work with incomplete dates and thus can return 0 when you might otherwise expect a nonzero value. For example:

```
mysql> SELECT DAYOFMONTH('2001-11-00'), MONTH('2005-00-00');
       -> 0, 0
```

Other functions expect complete dates and return `NULL` for incomplete dates. These include functions that perform date arithmetic or that map parts of dates to names. For example:

```
mysql> SELECT DATE_ADD('2006-05-00',INTERVAL 1 DAY);
       -> NULL
mysql> SELECT DAYNAME('2006-05-00');
       -> NULL
```

Several functions are strict when passed a `DATE()` function value as their argument and reject incomplete dates with a day part of zero: `CONVERT_TZ()`, `DATE_ADD()`, `DATE_SUB()`, `DAYOFYEAR()`, `TIMESTAMPDIFF()`, `TO_DAYS()`, `TO_SECONDS()`, `WEEK()`, `WEEKDAY()`, `WEEKOFYEAR()`, `YEARWEEK()`.

Fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values are supported, with up to microsecond precision. Functions that take temporal arguments accept values with fractional seconds. Return values from temporal functions include fractional seconds as appropriate.

- `ADDDATE(date,INTERVAL expr unit)`, `ADDDATE(expr,days)`

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see [Temporal Intervals](#).

```
mysql> SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
       -> '2008-02-02'
mysql> SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
       -> '2008-02-02'
```

When invoked with the `days` form of the second argument, MySQL treats it as an integer number of days to be added to `expr`.

```
mysql> SELECT ADDDATE('2008-01-02', 31);
       -> '2008-02-02'
```

- `ADDTIME(expr1,expr2)`

`ADDTIME()` adds `expr2` to `expr1` and returns the result. `expr1` is a time or datetime expression, and `expr2` is a time expression.

```
mysql> SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2008-01-02 01:01:01.000001'
mysql> SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
-> '03:00:01.999997'
```

- `CONVERT_TZ(dt, from_tz, to_tz)`

`CONVERT_TZ()` converts a datetime value *dt* from the time zone given by *from_tz* to the time zone given by *to_tz* and returns the resulting value. Time zones are specified as described in [Section 5.1.14, “MySQL Server Time Zone Support”](#). This function returns `NULL` if the arguments are invalid.

If the value falls out of the supported range of the `TIMESTAMP` type when converted from *from_tz* to UTC, no conversion occurs. The `TIMESTAMP` range is described in [Section 11.2.1, “Date and Time Data Type Syntax”](#).

```
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', 'GMT', 'MET');
-> '2004-01-01 13:00:00'
mysql> SELECT CONVERT_TZ('2004-01-01 12:00:00', '+00:00', '+10:00');
-> '2004-01-01 22:00:00'
```

Note

To use named time zones such as `'MET'` or `'Europe/Amsterdam'`, the time zone tables must be properly set up. For instructions, see [Section 5.1.14, “MySQL Server Time Zone Support”](#).

- `CURDATE()`

Returns the current date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in string or numeric context.

```
mysql> SELECT CURDATE();
-> '2008-06-13'
mysql> SELECT CURDATE() + 0;
-> 20080613
```

- `CURRENT_DATE`, `CURRENT_DATE()`

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms for `CURDATE()`.

- `CURRENT_TIME`, `CURRENT_TIME([fsp])`

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()`.

- `CURRENT_TIMESTAMP`, `CURRENT_TIMESTAMP([fsp])`

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()`.

- `CURTIME([fsp])`

Returns the current time as a value in `'hh:mm:ss'` or `hhmmss` format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT CURTIME();
-> '23:50:26'
mysql> SELECT CURTIME() + 0;
-> 235026.000000
```

- `DATE(expr)`

Extracts the date part of the date or datetime expression *expr*.

```
mysql> SELECT DATE('2003-12-31 01:02:03');
-> '2003-12-31'
```

- `DATEDIFF(expr1,expr2)`

`DATEDIFF()` returns *expr1* - *expr2* expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

```
mysql> SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
-> 1
mysql> SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
-> -31
```

- `DATE_ADD(date,INTERVAL expr unit),DATE_SUB(date,INTERVAL expr unit)`

These functions perform date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is evaluated as a string; it may start with a - for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted.

For more information about temporal interval syntax, including a full list of *unit* specifiers, the expected form of the *expr* argument for each *unit* value, and rules for operand interpretation in temporal arithmetic, see [Temporal Intervals](#).

The return value depends on the arguments:

- `DATE` if the *date* argument is a `DATE` value and your calculations involve only `YEAR`, `MONTH`, and `DAY` parts (that is, no time parts).
- `DATETIME` if the first argument is a `DATETIME` (or `TIMESTAMP`) value, or if the first argument is a `DATE` and the *unit* value uses `HOURS`, `MINUTES`, or `SECONDS`.
- String otherwise.

To ensure that the result is `DATETIME`, you can use `CAST()` to convert the first argument to `DATETIME`.

```
mysql> SELECT DATE_ADD('2018-05-01',INTERVAL 1 DAY);
-> '2018-05-02'
mysql> SELECT DATE_SUB('2018-05-01',INTERVAL 1 YEAR);
-> '2017-05-01'
mysql> SELECT DATE_ADD('2020-12-31 23:59:59',
-> INTERVAL 1 SECOND);
-> '2021-01-01 00:00:00'
mysql> SELECT DATE_ADD('2018-12-31 23:59:59',
-> INTERVAL 1 DAY);
-> '2019-01-01 23:59:59'
mysql> SELECT DATE_ADD('2100-12-31 23:59:59',
-> INTERVAL '1:1' MINUTE_SECOND);
-> '2101-01-01 00:01:00'
mysql> SELECT DATE_SUB('2025-01-01 00:00:00',
-> INTERVAL '1 1:1:1' DAY_SECOND);
-> '2024-12-30 22:58:59'
mysql> SELECT DATE_ADD('1900-01-01 00:00:00',
-> INTERVAL '-1 10' DAY_HOUR);
-> '1899-12-30 14:00:00'
mysql> SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
-> '1997-12-02'
mysql> SELECT DATE_ADD('1992-12-31 23:59:59.000002',
-> INTERVAL '1.999999' SECOND_MICROSECOND);
-> '1993-01-01 00:00:01.000001'
```

- `DATE_FORMAT(date,format)`

Formats the *date* value according to the *format* string.

The specifiers shown in the following table may be used in the *format* string. The `%` character is required before format specifier characters. The specifiers apply to other functions as well: `STR_TO_DATE()`, `TIME_FORMAT()`, `UNIX_TIMESTAMP()`.

Specifier	Description
<code>%a</code>	Abbreviated weekday name (<code>Sun..Sat</code>)
<code>%b</code>	Abbreviated month name (<code>Jan..Dec</code>)
<code>%c</code>	Month, numeric (<code>0..12</code>)
<code>%D</code>	Day of the month with English suffix (<code>0th, 1st, 2nd, 3rd, ...</code>)
<code>%d</code>	Day of the month, numeric (<code>00..31</code>)
<code>%e</code>	Day of the month, numeric (<code>0..31</code>)
<code>%f</code>	Microseconds (<code>000000..999999</code>)
<code>%H</code>	Hour (<code>00..23</code>)
<code>%h</code>	Hour (<code>01..12</code>)
<code>%I</code>	Hour (<code>01..12</code>)
<code>%i</code>	Minutes, numeric (<code>00..59</code>)
<code>%j</code>	Day of year (<code>001..366</code>)
<code>%k</code>	Hour (<code>0..23</code>)
<code>%l</code>	Hour (<code>1..12</code>)
<code>%M</code>	Month name (<code>January..December</code>)
<code>%m</code>	Month, numeric (<code>00..12</code>)
<code>%p</code>	<code>AM</code> or <code>PM</code>
<code>%r</code>	Time, 12-hour (<code>hh:mm:ss</code> followed by <code>AM</code> or <code>PM</code>)
<code>%S</code>	Seconds (<code>00..59</code>)
<code>%s</code>	Seconds (<code>00..59</code>)
<code>%T</code>	Time, 24-hour (<code>hh:mm:ss</code>)
<code>%U</code>	Week (<code>00..53</code>), where Sunday is the first day of the week; <code>WEEK()</code> mode 0
<code>%u</code>	Week (<code>00..53</code>), where Monday is the first day of the week; <code>WEEK()</code> mode 1
<code>%V</code>	Week (<code>01..53</code>), where Sunday is the first day of the week; <code>WEEK()</code> mode 2; used with <code>%X</code>
<code>%v</code>	Week (<code>01..53</code>), where Monday is the first day of the week; <code>WEEK()</code> mode 3; used with <code>%x</code>
<code>%W</code>	Weekday name (<code>Sunday..Saturday</code>)
<code>%w</code>	Day of the week (<code>0=Sunday..6=Saturday</code>)
<code>%X</code>	Year for the week where Sunday is the first day of the week, numeric, four digits; used with <code>%V</code>
<code>%x</code>	Year for the week, where Monday is the first day of the week, numeric, four digits; used with <code>%v</code>
<code>%Y</code>	Year, numeric, four digits
<code>%y</code>	Year, numeric (two digits)
<code>%%</code>	A literal <code>%</code> character

Specifier	Description
<code>%x</code>	<code>x</code> , for any “ <code>x</code> ” not listed above

Ranges for the month and day specifiers begin with zero due to the fact that MySQL permits the storing of incomplete dates such as `'2014-00-00'`.

The language used for day and month names and abbreviations is controlled by the value of the `lc_time_names` system variable (Section 10.16, “MySQL Server Locale Support”).

For the `%U`, `%u`, `%V`, and `%v` specifiers, see the description of the `WEEK()` function for information about the mode values. The mode affects how week numbering occurs.

`DATE_FORMAT()` returns a string with a character set and collation given by `character_set_connection` and `collation_connection` so that it can return month and weekday names containing non-ASCII characters.

```
mysql> SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
-> 'Sunday October 2009'
mysql> SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
-> '22:23:00'
mysql> SELECT DATE_FORMAT('1900-10-04 22:23:00',
->      '%D %y %a %d %m %b %j');
-> '4th 00 Thu 04 10 Oct 277'
mysql> SELECT DATE_FORMAT('1997-10-04 22:23:00',
->      '%H %k %I %r %T %S %w');
-> '22 22 10 10:23:00 PM 22:23:00 00 6'
mysql> SELECT DATE_FORMAT('1999-01-01', '%X %V');
-> '1998 52'
mysql> SELECT DATE_FORMAT('2006-06-00', '%d');
-> '00'
```

- `DATE_SUB(date, INTERVAL expr unit)`

See the description for `DATE_ADD()`.

- `DAY(date)`

`DAY()` is a synonym for `DAYOFMONTH()`.

- `DAYNAME(date)`

Returns the name of the weekday for `date`. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.16, “MySQL Server Locale Support”).

```
mysql> SELECT DAYNAME('2007-02-03');
-> 'Saturday'
```

- `DAYOFMONTH(date)`

Returns the day of the month for `date`, in the range 1 to 31, or 0 for dates such as `'0000-00-00'` or `'2008-00-00'` that have a zero day part.

```
mysql> SELECT DAYOFMONTH('2007-02-03');
-> 3
```

- `DAYOFWEEK(date)`

Returns the weekday index for `date` (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

```
mysql> SELECT DAYOFWEEK('2007-02-03');
-> 7
```

- `DAYOFYEAR(date)`

Returns the day of the year for *date*, in the range 1 to 366.

```
mysql> SELECT DAYOFYEAR('2007-02-03');
-> 34
```

- `EXTRACT(unit FROM date)`

The `EXTRACT()` function uses the same kinds of *unit* specifiers as `DATE_ADD()` or `DATE_SUB()`, but extracts parts from the date rather than performing date arithmetic. For information on the *unit* argument, see [Temporal Intervals](#).

```
mysql> SELECT EXTRACT(YEAR FROM '2019-07-02');
-> 2019
mysql> SELECT EXTRACT(YEAR_MONTH FROM '2019-07-02 01:02:03');
-> 201907
mysql> SELECT EXTRACT(DAY_MINUTE FROM '2019-07-02 01:02:03');
-> 20102
mysql> SELECT EXTRACT(MICROSECOND
-> FROM '2003-01-02 10:30:00.000123');
-> 123
```

- `FROM_DAYS(N)`

Given a day number *N*, returns a `DATE` value.

```
mysql> SELECT FROM_DAYS(730669);
-> '2000-07-03'
```

Use `FROM_DAYS()` with caution on old dates. It is not intended for use with values that precede the advent of the Gregorian calendar (1582). See [Section 12.9, “What Calendar Is Used By MySQL?”](#).

- `FROM_UNIXTIME(unix_timestamp[,format])`

Returns a representation of the *unix_timestamp* argument as a value in '`YYYY-MM-DD hh:mm:ss`' or `YYYYMMDDhhmmss` format, depending on whether the function is used in a string or numeric context. *unix_timestamp* is an internal timestamp value representing seconds since '`1970-01-01 00:00:00`' UTC, such as produced by the `UNIX_TIMESTAMP()` function.

The return value is expressed in the session time zone. (Clients can set the session time zone as described in [Section 5.1.14, “MySQL Server Time Zone Support”](#).) The *format* string, if given, is used to format the result the same way as described in the entry for the `DATE_FORMAT()` function.

```
mysql> SELECT FROM_UNIXTIME(1447430881);
-> '2015-11-13 10:08:01'
mysql> SELECT FROM_UNIXTIME(1447430881) + 0;
-> 20151113100801
mysql> SELECT FROM_UNIXTIME(1447430881,
-> '%Y %D %M %h:%i:%s %x');
-> '2015 13th November 10:08:01 2015'
```

Note

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For details, see the description of the `UNIX_TIMESTAMP()` function.

- `GET_FORMAT({DATE|TIME|DATETIME}, { 'EUR' | 'USA' | 'JIS' | 'ISO' | 'INTERNAL' })`

Returns a format string. This function is useful in combination with the `DATE_FORMAT()` and the `STR_TO_DATE()` functions.

The possible values for the first and second arguments result in several possible format strings (for the specifiers used, see the table in the `DATE_FORMAT()` function description). ISO format refers to ISO 9075, not ISO 8601.

Function Call	Result
<code>GET_FORMAT(DATE, 'USA')</code>	<code>'%m.%d.%Y'</code>
<code>GET_FORMAT(DATE, 'JIS')</code>	<code>'%Y-%m-%d'</code>
<code>GET_FORMAT(DATE, 'ISO')</code>	<code>'%Y-%m-%d'</code>
<code>GET_FORMAT(DATE, 'EUR')</code>	<code>'%d.%m.%Y'</code>
<code>GET_FORMAT(DATE, 'INTERNAL')</code>	<code>'%Y%m%d'</code>
<code>GET_FORMAT(DATETIME, 'USA')</code>	<code>'%Y-%m-%d %H.%i.%s'</code>
<code>GET_FORMAT(DATETIME, 'JIS')</code>	<code>'%Y-%m-%d %H:%i:%s'</code>
<code>GET_FORMAT(DATETIME, 'ISO')</code>	<code>'%Y-%m-%d %H:%i:%s'</code>
<code>GET_FORMAT(DATETIME, 'EUR')</code>	<code>'%Y-%m-%d %H.%i.%s'</code>
<code>GET_FORMAT(DATETIME, 'INTERNAL')</code>	<code>'%Y%m%d%H%i%s'</code>
<code>GET_FORMAT(TIME, 'USA')</code>	<code>'%h:%i:%s p'</code>
<code>GET_FORMAT(TIME, 'JIS')</code>	<code>'%H:%i:%s'</code>
<code>GET_FORMAT(TIME, 'ISO')</code>	<code>'%H:%i:%s'</code>
<code>GET_FORMAT(TIME, 'EUR')</code>	<code>'%H.%i.%s'</code>
<code>GET_FORMAT(TIME, 'INTERNAL')</code>	<code>'%H%i%s'</code>

`TIMESTAMP` can also be used as the first argument to `GET_FORMAT()`, in which case the function returns the same values as for `DATETIME`.

```
mysql> SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
-> '03.10.2003'
mysql> SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
-> '2003-10-31'
```

- `HOURL(time)`

Returns the hour for *time*. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so `HOURL` can return values greater than 23.

```
mysql> SELECT HOURL('10:05:03');
-> 10
mysql> SELECT HOURL('272:59:59');
-> 272
```

- `LAST_DAY(date)`

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns `NULL` if the argument is invalid.

```
mysql> SELECT LAST_DAY('2003-02-05');
-> '2003-02-28'
mysql> SELECT LAST_DAY('2004-02-05');
-> '2004-02-29'
mysql> SELECT LAST_DAY('2004-01-01 01:01:01');
-> '2004-01-31'
mysql> SELECT LAST_DAY('2003-03-32');
-> NULL
```

- `LOCALTIME, LOCALTIME([fsp])`

`LOCALTIME` and `LOCALTIME()` are synonyms for `NOW()`.

- `LOCALTIMESTAMP, LOCALTIMESTAMP([fsp])`

`LOCALTIMESTAMP` and `LOCALTIMESTAMP()` are synonyms for `NOW()`.

- `MAKEDATE(year, dayofyear)`

Returns a date, given year and day-of-year values. *dayofyear* must be greater than 0 or the result is `NULL`.

```
mysql> SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
      -> '2011-01-31', '2011-02-01'
mysql> SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
      -> '2011-12-31', '2014-12-31'
mysql> SELECT MAKEDATE(2011,0);
      -> NULL
```

- `MAKETIME(hour, minute, second)`

Returns a time value calculated from the *hour*, *minute*, and *second* arguments.

The *second* argument can have a fractional part.

```
mysql> SELECT MAKETIME(12,15,30);
      -> '12:15:30'
```

- `MICROSECOND(expr)`

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

```
mysql> SELECT MICROSECOND('12:00:00.123456');
      -> 123456
mysql> SELECT MICROSECOND('2019-12-31 23:59:59.000010');
      -> 10
```

- `MINUTE(time)`

Returns the minute for *time*, in the range 0 to 59.

```
mysql> SELECT MINUTE('2008-02-03 10:05:03');
      -> 5
```

- `MONTH(date)`

Returns the month for *date*, in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

```
mysql> SELECT MONTH('2008-02-03');
      -> 2
```

- `MONTHNAME(date)`

Returns the full name of the month for *date*. The language used for the name is controlled by the value of the `lc_time_names` system variable (Section 10.16, “MySQL Server Locale Support”).

```
mysql> SELECT MONTHNAME('2008-02-03');
      -> 'February'
```

- `NOW([fsp])`

Returns the current date and time as a value in 'YYYY-MM-DD hh:mm:ss' or YYYYMMDDhhmmss format, depending on whether the function is used in string or numeric context. The value is expressed in the session time zone.

If the *fsp* argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT NOW();
-> '2007-12-15 23:50:26'
mysql> SELECT NOW() + 0;
-> 20071215235026.000000
```

`NOW()` returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.) This differs from the behavior for `SYSDATE()`, which returns the exact time at which it executes.

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE() | SLEEP(2) | SYSDATE() |
+-----+-----+-----+
| 2006-04-12 13:47:44 | 0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. Setting the timestamp to a nonzero value causes each subsequent invocation of `NOW()` to return that value. Setting the timestamp to zero cancels this effect so that `NOW()` once again returns the current date and time.

See the description for `SYSDATE()` for additional information about the differences between the two functions.

- `PERIOD_ADD(P,N)`

Adds *N* months to period *P* (in the format *YYMM* or *YYYYMM*). Returns a value in the format *YYYYMM*.

Note

The period argument *P* is *not* a date value.

```
mysql> SELECT PERIOD_ADD(200801,2);
-> 200803
```

- `PERIOD_DIFF(P1,P2)`

Returns the number of months between periods *P1* and *P2*. *P1* and *P2* should be in the format *YYMM* or *YYYYMM*. Note that the period arguments *P1* and *P2* are *not* date values.

```
mysql> SELECT PERIOD_DIFF(200802,200703);
-> 11
```

- `QUARTER(date)`

Returns the quarter of the year for *date*, in the range 1 to 4.

```
mysql> SELECT QUARTER('2008-04-01');
-> 2
```

- `SECOND(time)`

Returns the second for *time*, in the range 0 to 59.

```
mysql> SELECT SECOND('10:05:03');
-> 3
```

- `SEC_TO_TIME(seconds)`

Returns the *seconds* argument, converted to hours, minutes, and seconds, as a `TIME` value. The range of the result is constrained to that of the `TIME` data type. A warning occurs if the argument corresponds to a value outside that range.

```
mysql> SELECT SEC_TO_TIME(2378);
-> '00:39:38'
mysql> SELECT SEC_TO_TIME(2378) + 0;
-> 3938
```

- `STR_TO_DATE(str,format)`

This is the inverse of the `DATE_FORMAT()` function. It takes a string *str* and a format string *format*. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts. If the date, time, or datetime value extracted from *str* is illegal, `STR_TO_DATE()` returns `NULL` and produces a warning.

The server scans *str* attempting to match *format* to it. The format string can contain literal characters and format specifiers beginning with `%`. Literal characters in *format* must match literally in *str*. Format specifiers in *format* must match a date or time part in *str*. For the specifiers that can be used in *format*, see the `DATE_FORMAT()` function description.

```
mysql> SELECT STR_TO_DATE('01,5,2013','%d,%m,%Y');
-> '2013-05-01'
mysql> SELECT STR_TO_DATE('May 1, 2013','%M %d,%Y');
-> '2013-05-01'
```

Scanning starts at the beginning of *str* and fails if *format* is found not to match. Extra characters at the end of *str* are ignored.

```
mysql> SELECT STR_TO_DATE('a09:30:17','a%h:%i:%s');
-> '09:30:17'
mysql> SELECT STR_TO_DATE('a09:30:17','%h:%i:%s');
-> NULL
mysql> SELECT STR_TO_DATE('09:30:17a','%h:%i:%s');
-> '09:30:17'
```

Unspecified date or time parts have a value of 0, so incompletely specified values in *str* produce a result with some or all parts set to 0:

```
mysql> SELECT STR_TO_DATE('abc','abc');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('9','%m');
-> '0000-09-00'
mysql> SELECT STR_TO_DATE('9','%s');
-> '00:00:09'
```

Range checking on the parts of date values is as described in [Section 11.2.2, “The DATE, DATETIME, and TIMESTAMP Types”](#). This means, for example, that “zero” dates or dates with part values of 0 are permitted unless the SQL mode is set to disallow such values.

```
mysql> SELECT STR_TO_DATE('00/00/0000','%m/%d/%Y');
-> '0000-00-00'
mysql> SELECT STR_TO_DATE('04/31/2004','%m/%d/%Y');
```

```
-> '2004-04-31'
```

If the `NO_ZERO_DATE` SQL mode is enabled, zero dates are disallowed. In that case, `STR_TO_DATE()` returns `NULL` and generates a warning:

```
mysql> SET sql_mode = '';
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
+-----+
| STR_TO_DATE('00/00/0000', '%m/%d/%Y') |
+-----+
| 0000-00-00                             |
+-----+
mysql> SET sql_mode = 'NO_ZERO_DATE';
mysql> SELECT STR_TO_DATE('00/00/0000', '%m/%d/%Y');
+-----+
| STR_TO_DATE('00/00/0000', '%m/%d/%Y') |
+-----+
| NULL                                   |
+-----+
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1411
Message: Incorrect datetime value: '00/00/0000' for function str_to_date
```

Note

You cannot use format `"%X%V"` to convert a year-week string to a date because the combination of a year and week does not uniquely identify a year and month if the week crosses a month boundary. To convert a year-week to a date, you should also specify the weekday:

```
mysql> SELECT STR_TO_DATE('200442 Monday', '%X%V %W');
-> '2004-10-18'
```

- `SUBDATE(date, INTERVAL expr unit), SUBDATE(expr, days)`

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL unit` argument, see the discussion for `DATE_ADD()`.

```
mysql> SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
mysql> SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
-> '2007-12-02'
```

The second form enables the use of an integer value for *days*. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression *expr*.

```
mysql> SELECT SUBDATE('2008-01-02 12:00:00', 31);
-> '2007-12-02 12:00:00'
```

- `SUBTIME(expr1, expr2)`

`SUBTIME()` returns `expr1 - expr2` expressed as a value in the same format as *expr1*. *expr1* is a time or datetime expression, and *expr2* is a time expression.

```
mysql> SELECT SUBTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
-> '2007-12-30 22:58:58.999997'
mysql> SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
-> '-00:59:59.999999'
```

- `SYSDATE([fsp])`

Returns the current date and time as a value in `'YYYY-MM-DD hh:mm:ss'` or `YYYYMMDDhhmmss` format, depending on whether the function is used in string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

`SYSDATE()` returns the time at which it executes. This differs from the behavior for `NOW()`, which returns a constant time that indicates the time at which the statement began to execute. (Within a stored function or trigger, `NOW()` returns the time at which the function or triggering statement began to execute.)

```
mysql> SELECT NOW(), SLEEP(2), NOW();
+-----+-----+-----+
| NOW() | SLEEP(2) | NOW() |
+-----+-----+-----+
| 2006-04-12 13:47:36 | 0 | 2006-04-12 13:47:36 |
+-----+-----+-----+

mysql> SELECT SYSDATE(), SLEEP(2), SYSDATE();
+-----+-----+-----+
| SYSDATE() | SLEEP(2) | SYSDATE() |
+-----+-----+-----+
| 2006-04-12 13:47:44 | 0 | 2006-04-12 13:47:46 |
+-----+-----+-----+
```

In addition, the `SET TIMESTAMP` statement affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`.

Because `SYSDATE()` can return different values even within the same statement, and is not affected by `SET TIMESTAMP`, it is nondeterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging.

Alternatively, you can use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This works if the option is used on both the replication source server and the replica.

The nondeterministic nature of `SYSDATE()` also means that indexes cannot be used for evaluating expressions that refer to it.

- `TIME(expr)`

Extracts the time part of the time or datetime expression `expr` and returns it as a string.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT TIME('2003-12-31 01:02:03');
-> '01:02:03'
mysql> SELECT TIME('2003-12-31 01:02:03.000123');
-> '01:02:03.000123'
```

- `TIMEDIFF(expr1,expr2)`

`TIMEDIFF()` returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are time or date-and-time expressions, but both must be of the same type.

The result returned by `TIMEDIFF()` is limited to the range allowed for `TIME` values. Alternatively, you can use either of the functions `TIMESTAMPDIFF()` and `UNIX_TIMESTAMP()`, both of which return integers.

```
mysql> SELECT TIMEDIFF('2000:01:01 00:00:00',
-> '2000:01:01 00:00:00.000001');
-> '-00:00:00.000001'
```

```
mysql> SELECT TIMEDIFF('2008-12-31 23:59:59.000001',
-> '2008-12-30 01:01:01.000002');
-> '46:58:57.999999'
```

- `TIMESTAMP(expr)`, `TIMESTAMP(expr1,expr2)`

With a single argument, this function returns the date or datetime expression *expr* as a datetime value. With two arguments, it adds the time expression *expr2* to the date or datetime expression *expr1* and returns the result as a datetime value.

```
mysql> SELECT TIMESTAMP('2003-12-31');
-> '2003-12-31 00:00:00'
mysql> SELECT TIMESTAMP('2003-12-31 12:00:00','12:00:00');
-> '2004-01-01 00:00:00'
```

- `TIMESTAMPADD(unit,interval,datetime_expr)`

Adds the integer expression *interval* to the date or datetime expression *datetime_expr*. The unit for *interval* is given by the *unit* argument, which should be one of the following values: `MICROSECOND` (microseconds), `SECOND`, `MINUTE`, `HOURL`, `DAY`, `WEEK`, `MONTH`, `QUARTER`, or `YEAR`.

The *unit* value may be specified using one of keywords as shown, or with a prefix of `SQL_TSI_`. For example, `DAY` and `SQL_TSI_DAY` both are legal.

```
mysql> SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
-> '2003-01-02 00:01:00'
mysql> SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
-> '2003-01-09'
```

- `TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)`

Returns *datetime_expr2* - *datetime_expr1*, where *datetime_expr1* and *datetime_expr2* are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the *unit* argument. The legal values for *unit* are the same as those listed in the description of the `TIMESTAMPADD()` function.

```
mysql> SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
-> 3
mysql> SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
-> -1
mysql> SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
-> 128885
```

Note

The order of the date or datetime arguments for this function is the opposite of that used with the `TIMESTAMP()` function when invoked with 2 arguments.

- `TIME_FORMAT(time,format)`

This is used like the `DATE_FORMAT()` function, but the *format* string may contain format specifiers only for hours, minutes, seconds, and microseconds. Other specifiers produce a `NULL` value or `0`.

If the *time* value contains an hour part that is greater than 23, the `%H` and `%k` hour format specifiers produce a value larger than the usual range of 0..23. The other hour format specifiers produce the hour value modulo 12.

```
mysql> SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
-> '100 100 04 04 4'
```

- `TIME_TO_SEC(time)`

Returns the *time* argument, converted to seconds.

```
mysql> SELECT TIME_TO_SEC('22:23:00');
```

```

-> 80580
mysql> SELECT TIME_TO_SEC('00:39:38');
-> 2378

```

- `TO_DAYS(date)`

Given a date *date*, returns a day number (the number of days since year 0).

```

mysql> SELECT TO_DAYS(950501);
-> 728779
mysql> SELECT TO_DAYS('2007-10-07');
-> 733321

```

`TO_DAYS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 12.9, “What Calendar Is Used By MySQL?”](#), for details.

Remember that MySQL converts two-digit year values in dates to four-digit form using the rules in [Section 11.2, “Date and Time Data Types”](#). For example, `'2008-10-07'` and `'08-10-07'` are seen as identical dates:

```

mysql> SELECT TO_DAYS('2008-10-07'), TO_DAYS('08-10-07');
-> 733687, 733687

```

In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_DAYS()` returns the values shown here:

```

mysql> SELECT TO_DAYS('0000-00-00');
+-----+
| to_days('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_DAYS('0000-01-01');
+-----+
| to_days('0000-01-01') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `TO_SECONDS(expr)`

Given a date or datetime *expr*, returns the number of seconds since the year 0. If *expr* is not a valid date or datetime value, returns `NULL`.

```

mysql> SELECT TO_SECONDS(950501);
-> 62966505600
mysql> SELECT TO_SECONDS('2009-11-29');
-> 63426672000
mysql> SELECT TO_SECONDS('2009-11-29 13:43:32');
-> 63426721412
mysql> SELECT TO_SECONDS( NOW() );

```

```
-> 63426721458
```

Like `TO_DAYS()`, `TO_SECONDS()` is not intended for use with values that precede the advent of the Gregorian calendar (1582), because it does not take into account the days that were lost when the calendar was changed. For dates before 1582 (and possibly a later year in other locales), results from this function are not reliable. See [Section 12.9, “What Calendar Is Used By MySQL?”](#), for details.

Like `TO_DAYS()`, `TO_SECONDS()`, converts two-digit year values in dates to four-digit form using the rules in [Section 11.2, “Date and Time Data Types”](#).

In MySQL, the zero date is defined as `'0000-00-00'`, even though this date is itself considered invalid. This means that, for `'0000-00-00'` and `'0000-01-01'`, `TO_SECONDS()` returns the values shown here:

```
mysql> SELECT TO_SECONDS('0000-00-00');
+-----+
| TO_SECONDS('0000-00-00') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Incorrect datetime value: '0000-00-00' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT TO_SECONDS('0000-01-01');
+-----+
| TO_SECONDS('0000-01-01') |
+-----+
| 86400 |
+-----+
1 row in set (0.00 sec)
```

This is true whether or not the `ALLOW_INVALID_DATES` SQL server mode is enabled.

- `UNIX_TIMESTAMP([date])`

If `UNIX_TIMESTAMP()` is called with no *date* argument, it returns a Unix timestamp representing seconds since `'1970-01-01 00:00:00'` UTC.

If `UNIX_TIMESTAMP()` is called with a *date* argument, it returns the value of the argument as seconds since `'1970-01-01 00:00:00'` UTC. The server interprets *date* as a value in the session time zone and converts it to an internal Unix timestamp value in UTC. (Clients can set the session time zone as described in [Section 5.1.14, “MySQL Server Time Zone Support”](#).) The *date* argument may be a `DATE`, `DATETIME`, or `TIMESTAMP` string, or a number in `YYMMDD`,

`YYMMDDhhmmss`, `YYYYMMDD`, or `YYYYMMDDhhmmss` format. If the argument includes a time part, it may optionally include a fractional seconds part.

The return value is an integer if no argument is given or the argument does not include a fractional seconds part, or `DECIMAL` if an argument is given that includes a fractional seconds part.

When the *date* argument is a `TIMESTAMP` column, `UNIX_TIMESTAMP()` returns the internal timestamp value directly, with no implicit “string-to-Unix-timestamp” conversion.

The valid range of argument values is the same as for the `TIMESTAMP` data type: `'1970-01-01 00:00:01.000000'` UTC to `'2038-01-19 03:14:07.999999'` UTC. If you pass an out-of-range date to `UNIX_TIMESTAMP()`, it returns 0.

```
mysql> SELECT UNIX_TIMESTAMP();
-> 1447431666
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19');
-> 1447431619
mysql> SELECT UNIX_TIMESTAMP('2015-11-13 10:20:19.012');
-> 1447431619.012
```

If you use `UNIX_TIMESTAMP()` and `FROM_UNIXTIME()` to convert between values in a non-UTC time zone and Unix timestamp values, the conversion is lossy because the mapping is not one-to-one in both directions. For example, due to conventions for local time zone changes such as Daylight Saving Time (DST), it is possible for `UNIX_TIMESTAMP()` to map two values that are distinct in a non-UTC time zone to the same Unix timestamp value. `FROM_UNIXTIME()` will map that value back to only one of the original values. Here is an example, using values that are distinct in the `MET` time zone:

```
mysql> SET time_zone = 'MET';
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 03:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 03:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT UNIX_TIMESTAMP('2005-03-27 02:00:00');
+-----+
| UNIX_TIMESTAMP('2005-03-27 02:00:00') |
+-----+
| 1111885200 |
+-----+
mysql> SELECT FROM_UNIXTIME(1111885200);
+-----+
| FROM_UNIXTIME(1111885200) |
+-----+
| 2005-03-27 03:00:00 |
+-----+
```

Note

To use named time zones such as `'MET'` or `'Europe/Amsterdam'`, the time zone tables must be properly set up. For instructions, see [Section 5.1.14, “MySQL Server Time Zone Support”](#).

If you want to subtract `UNIX_TIMESTAMP()` columns, you might want to cast them to signed integers. See [Section 12.11, “Cast Functions and Operators”](#).

- `UTC_DATE`, `UTC_DATE()`

Returns the current UTC date as a value in `'YYYY-MM-DD'` or `YYYYMMDD` format, depending on whether the function is used in string or numeric context.

```
mysql> SELECT UTC_DATE(), UTC_DATE() + 0;
-> '2003-08-14', 20030814
```

- `UTC_TIME`, `UTC_TIME([fsp])`

Returns the current UTC time as a value in `'hh:mm:ss'` or `hhmmss` format, depending on whether the function is used in string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT UTC_TIME(), UTC_TIME() + 0;
-> '18:07:53', 180753.000000
```

- `UTC_TIMESTAMP`, `UTC_TIMESTAMP([fsp])`

Returns the current UTC date and time as a value in `'YYYY-MM-DD hh:mm:ss'` or `YYYYMMDDhhmmss` format, depending on whether the function is used in string or numeric context.

If the `fsp` argument is given to specify a fractional seconds precision from 0 to 6, the return value includes a fractional seconds part of that many digits.

```
mysql> SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
-> '2003-08-14 18:08:04', 20030814180804.000000
```

- `WEEK(date[,mode])`

This function returns the week number for `date`. The two-argument form of `WEEK()` enables you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the `mode` argument is omitted, the value of the `default_week_format` system variable is used. See [Section 5.1.8, “Server System Variables”](#).

The following table describes how the `mode` argument works.

Mode	First day of week	Range	Week 1 is the first week ...
0	Sunday	0-53	with a Sunday in this year
1	Monday	0-53	with 4 or more days this year
2	Sunday	1-53	with a Sunday in this year
3	Monday	1-53	with 4 or more days this year
4	Sunday	0-53	with 4 or more days this year
5	Monday	0-53	with a Monday in this year
6	Sunday	1-53	with 4 or more days this year
7	Monday	1-53	with a Monday in this year

For `mode` values with a meaning of “with 4 or more days this year,” weeks are numbered according to ISO 8601:1988:

- If the week containing January 1 has 4 or more days in the new year, it is week 1.
- Otherwise, it is the last week of the previous year, and the next week is week 1.

```
mysql> SELECT WEEK('2008-02-20');
-> 7
mysql> SELECT WEEK('2008-02-20',0);
-> 7
mysql> SELECT WEEK('2008-02-20',1);
-> 8
mysql> SELECT WEEK('2008-12-31',1);
```

```
-> 53
```

If a date falls in the last week of the previous year, MySQL returns 0 if you do not use 2, 3, 6, or 7 as the optional *mode* argument:

```
mysql> SELECT YEAR('2000-01-01'), WEEK('2000-01-01',0);
-> 2000, 0
```

One might argue that `WEEK()` should return 52 because the given date actually occurs in the 52nd week of 1999. `WEEK()` returns 0 instead so that the return value is “the week number in the given year.” This makes use of the `WEEK()` function reliable when combined with other functions that extract a date part from a date.

If you prefer a result evaluated with respect to the year that contains the first day of the week for the given date, use 0, 2, 5, or 7 as the optional *mode* argument.

```
mysql> SELECT WEEK('2000-01-01',2);
-> 52
```

Alternatively, use the `YEARWEEK()` function:

```
mysql> SELECT YEARWEEK('2000-01-01');
-> 199952
mysql> SELECT MID(YEARWEEK('2000-01-01'),5,2);
-> '52'
```

- `WEEKDAY(date)`

Returns the weekday index for *date* (0 = Monday, 1 = Tuesday, ... 6 = Sunday).

```
mysql> SELECT WEEKDAY('2008-02-03 22:23:00');
-> 6
mysql> SELECT WEEKDAY('2007-11-06');
-> 1
```

- `WEEKOFYEAR(date)`

Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date, 3)`.

```
mysql> SELECT WEEKOFYEAR('2008-02-20');
-> 8
```

- `YEAR(date)`

Returns the year for *date*, in the range 1000 to 9999, or 0 for the “zero” date.

```
mysql> SELECT YEAR('1987-01-01');
-> 1987
```

- `YEARWEEK(date)`, `YEARWEEK(date, mode)`

Returns year and week for a date. The year in the result may be different from the year in the date argument for the first and the last week of the year.

The *mode* argument works exactly like the *mode* argument to `WEEK()`. For the single-argument syntax, a *mode* value of 0 is used. Unlike `WEEK()`, the value of `default_week_format` does not influence `YEARWEEK()`.

```
mysql> SELECT YEARWEEK('1987-01-01');
-> 198652
```

The week number is different from what the `WEEK()` function would return (0) for optional arguments 0 or 1, as `WEEK()` then returns the week in the context of the given year.

12.8 String Functions and Operators

Table 12.12 String Functions and Operators

Name	Description
<code>ASCII ()</code>	Return numeric value of left-most character
<code>BIN ()</code>	Return a string containing binary representation of a number
<code>BIT_LENGTH ()</code>	Return length of argument in bits
<code>CHAR ()</code>	Return the character for each integer passed
<code>CHAR_LENGTH ()</code>	Return number of characters in argument
<code>CHARACTER_LENGTH ()</code>	Synonym for <code>CHAR_LENGTH()</code>
<code>CONCAT ()</code>	Return concatenated string
<code>CONCAT_WS ()</code>	Return concatenate with separator
<code>ELT ()</code>	Return string at index number
<code>EXPORT_SET ()</code>	Return a string such that for every bit set in the value bits, you get an on string and for every unset bit, you get an off string
<code>FIELD ()</code>	Index (position) of first argument in subsequent arguments
<code>FIND_IN_SET ()</code>	Index (position) of first argument within second argument
<code>FORMAT ()</code>	Return a number formatted to specified number of decimal places
<code>FROM_BASE64 ()</code>	Decode base64 encoded string and return result
<code>HEX ()</code>	Hexadecimal representation of decimal or string value
<code>INSERT ()</code>	Insert substring at specified position up to specified number of characters
<code>INSTR ()</code>	Return the index of the first occurrence of substring
<code>LCASE ()</code>	Synonym for <code>LOWER()</code>
<code>LEFT ()</code>	Return the leftmost number of characters as specified
<code>LENGTH ()</code>	Return the length of a string in bytes
<code>LIKE</code>	Simple pattern matching
<code>LOAD_FILE ()</code>	Load the named file
<code>LOCATE ()</code>	Return the position of the first occurrence of substring
<code>LOWER ()</code>	Return the argument in lowercase
<code>LPAD ()</code>	Return the string argument, left-padded with the specified string
<code>LTRIM ()</code>	Remove leading spaces
<code>MAKE_SET ()</code>	Return a set of comma-separated strings that have the corresponding bit in bits set
<code>MATCH</code>	Perform full-text search
<code>MID ()</code>	Return a substring starting from the specified position
<code>NOT LIKE</code>	Negation of simple pattern matching
<code>NOT REGEXP</code>	Negation of <code>REGEXP</code>
<code>OCT ()</code>	Return a string containing octal representation of a number
<code>OCTET_LENGTH ()</code>	Synonym for <code>LENGTH()</code>
<code>ORD ()</code>	Return character code for leftmost character of the argument

Name	Description
<code>POSITION()</code>	Synonym for <code>LOCATE()</code>
<code>QUOTE()</code>	Escape the argument for use in an SQL statement
<code>REGEXP</code>	Whether string matches regular expression
<code>REGEXP_INSTR()</code>	Starting index of substring matching regular expression
<code>REGEXP_LIKE()</code>	Whether string matches regular expression
<code>REGEXP_REPLACE()</code>	Replace substrings matching regular expression
<code>REGEXP_SUBSTR()</code>	Return substring matching regular expression
<code>REPEAT()</code>	Repeat a string the specified number of times
<code>REPLACE()</code>	Replace occurrences of a specified string
<code>REVERSE()</code>	Reverse the characters in a string
<code>RIGHT()</code>	Return the specified rightmost number of characters
<code>RLIKE</code>	Whether string matches regular expression
<code>RPAD()</code>	Append string the specified number of times
<code>RTRIM()</code>	Remove trailing spaces
<code>SOUNDEX()</code>	Return a soundex string
<code>SOUNDS LIKE</code>	Compare sounds
<code>SPACE()</code>	Return a string of the specified number of spaces
<code>STRCMP()</code>	Compare two strings
<code>SUBSTR()</code>	Return the substring as specified
<code>SUBSTRING()</code>	Return the substring as specified
<code>SUBSTRING_INDEX()</code>	Return a substring from a string before the specified number of occurrences of the delimiter
<code>TO_BASE64()</code>	Return the argument converted to a base-64 string
<code>TRIM()</code>	Remove leading and trailing spaces
<code>UCASE()</code>	Synonym for <code>UPPER()</code>
<code>UNHEX()</code>	Return a string containing hex representation of a number
<code>UPPER()</code>	Convert to uppercase
<code>WEIGHT_STRING()</code>	Return the weight string for a string

String-valued functions return `NULL` if the length of the result would be greater than the value of the `max_allowed_packet` system variable. See [Section 5.1.1, “Configuring the Server”](#).

For functions that operate on string positions, the first position is numbered 1.

For functions that take length arguments, noninteger arguments are rounded to the nearest integer.

- `ASCII(str)`

Returns the numeric value of the leftmost character of the string `str`. Returns 0 if `str` is the empty string. Returns `NULL` if `str` is `NULL`. `ASCII()` works for 8-bit characters.

```
mysql> SELECT ASCII('2');
-> 50
mysql> SELECT ASCII(2);
-> 50
mysql> SELECT ASCII('dx');
-> 100
```

See also the `ORD()` function.

- `BIN(N)`

Returns a string representation of the binary value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,2)`. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT BIN(12);
-> '1100'
```

- `BIT_LENGTH(str)`

Returns the length of the string *str* in bits.

```
mysql> SELECT BIT_LENGTH('text');
-> 32
```

- `CHAR(N,... [USING charset_name])`

`CHAR()` interprets each argument *N* as an integer and returns a string consisting of the characters given by the code values of those integers. `NULL` values are skipped.

```
mysql> SELECT CHAR(77,121,83,81,'76');
-> 'MySQL'
mysql> SELECT CHAR(77,77.3,'77.3');
-> 'MMM'
```

`CHAR()` arguments larger than 255 are converted into multiple result bytes. For example, `CHAR(256)` is equivalent to `CHAR(1,0)`, and `CHAR(256*256)` is equivalent to `CHAR(1,0,0)`:

```
mysql> SELECT HEX(CHAR(1,0)), HEX(CHAR(256));
+-----+-----+
| HEX(CHAR(1,0)) | HEX(CHAR(256)) |
+-----+-----+
| 0100          | 0100          |
+-----+-----+
mysql> SELECT HEX(CHAR(1,0,0)), HEX(CHAR(256*256));
+-----+-----+
| HEX(CHAR(1,0,0)) | HEX(CHAR(256*256)) |
+-----+-----+
| 010000          | 010000          |
+-----+-----+
```

By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```
mysql> SELECT CHARSET(CHAR(X'65')), CHARSET(CHAR(X'65' USING utf8));
+-----+-----+
| CHARSET(CHAR(X'65')) | CHARSET(CHAR(X'65' USING utf8)) |
+-----+-----+
| binary              | utf8                            |
+-----+-----+
```

If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes `NULL`.

- `CHAR_LENGTH(str)`

Returns the length of the string *str*, measured in characters. A multibyte character counts as a single character. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

- `CHARACTER_LENGTH(str)`

`CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

- `CONCAT(str1,str2,...)`

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are nonbinary strings, the result is a nonbinary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent nonbinary string form.

`CONCAT()` returns `NULL` if any argument is `NULL`.

```
mysql> SELECT CONCAT('My', 'S', 'QL');
      -> 'MySQL'
mysql> SELECT CONCAT('My', NULL, 'QL');
      -> NULL
mysql> SELECT CONCAT(14.3);
      -> '14.3'
```

For quoted strings, concatenation can be performed by placing the strings next to each other:

```
mysql> SELECT 'My' 'S' 'QL';
      -> 'MySQL'
```

- `CONCAT_WS(separator,str1,str2,...)`

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments. If the separator is `NULL`, the result is `NULL`.

```
mysql> SELECT CONCAT_WS(',', 'First name', 'Second name', 'Last Name');
      -> 'First name,Second name,Last Name'
mysql> SELECT CONCAT_WS(',', 'First name', NULL, 'Last Name');
      -> 'First name,Last Name'
```

`CONCAT_WS()` does not skip empty strings. However, it does skip any `NULL` values after the separator argument.

- `ELT(N,str1,str2,str3,...)`

`ELT()` returns the *N*th element of the list of strings: *str1* if *N* = 1, *str2* if *N* = 2, and so on. Returns `NULL` if *N* is less than 1 or greater than the number of arguments. `ELT()` is the complement of `FIELD()`.

```
mysql> SELECT ELT(1, 'Aa', 'Bb', 'Cc', 'Dd');
      -> 'Aa'
mysql> SELECT ELT(4, 'Aa', 'Bb', 'Cc', 'Dd');
      -> 'Dd'
```

- `EXPORT_SET(bits,on,off[,separator[,number_of_bits]])`

Returns a string such that for every bit set in the value *bits*, you get an *on* string and for every bit not set in the value, you get an *off* string. Bits in *bits* are examined from right to left (from low-order to high-order bits). Strings are added to the result from left to right, separated by the *separator* string (the default being the comma character ,). The number of bits examined is given by *number_of_bits*, which has a default of 64 if not specified. *number_of_bits* is silently clipped to 64 if larger than 64. It is treated as an unsigned integer, so a value of -1 is effectively the same as 64.

```
mysql> SELECT EXPORT_SET(5, 'Y', 'N', ',', 4);
      -> 'Y,N,Y,N'
mysql> SELECT EXPORT_SET(6, '1', '0', ',', 10);
      -> '0,1,1,0,0,0,0,0,0,0'
```

- `FIELD(str,str1,str2,str3,...)`

Returns the index (position) of *str* in the *str1, str2, str3, ...* list. Returns 0 if *str* is not found.

If all arguments to `FIELD()` are strings, all arguments are compared as strings. If all arguments are numbers, they are compared as numbers. Otherwise, the arguments are compared as double.

If `str` is `NULL`, the return value is 0 because `NULL` fails equality comparison with any value. `FIELD()` is the complement of `ELT()`.

```
mysql> SELECT FIELD('Bb', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 2
mysql> SELECT FIELD('Gg', 'Aa', 'Bb', 'Cc', 'Dd', 'Ff');
-> 0
```

- `FIND_IN_SET(str, strlist)`

Returns a value in the range of 1 to `N` if the string `str` is in the string list `strlist` consisting of `N` substrings. A string list is a string composed of substrings separated by `,` characters. If the first argument is a constant string and the second is a column of type `SET`, the `FIND_IN_SET()` function is optimized to use bit arithmetic. Returns 0 if `str` is not in `strlist` or if `strlist` is the empty string. Returns `NULL` if either argument is `NULL`. This function does not work properly if the first argument contains a comma `,` character.

```
mysql> SELECT FIND_IN_SET('b', 'a,b,c,d');
-> 2
```

- `FORMAT(X, D[, locale])`

Formats the number `X` to a format like `'#,###,###.##'`, rounded to `D` decimal places, and returns the result as a string. If `D` is 0, the result has no decimal point or fractional part.

The optional third parameter enables a locale to be specified to be used for the result number's decimal point, thousands separator, and grouping between separators. Permissible locale values are the same as the legal values for the `lc_time_names` system variable (see [Section 10.16, "MySQL Server Locale Support"](#)). If no locale is specified, the default is `'en_US'`.

```
mysql> SELECT FORMAT(12332.123456, 4);
-> '12,332.1235'
mysql> SELECT FORMAT(12332.1, 4);
-> '12,332.1000'
mysql> SELECT FORMAT(12332.2, 0);
-> '12,332'
mysql> SELECT FORMAT(12332.2, 2, 'de_DE');
-> '12.332,20'
```

- `FROM_BASE64(str)`

Takes a string encoded with the base-64 encoded rules used by `TO_BASE64()` and returns the decoded result as a binary string. The result is `NULL` if the argument is `NULL` or not a valid base-64 string. See the description of `TO_BASE64()` for details about the encoding and decoding rules.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

- `HEX(str)`, `HEX(N)`

For a string argument `str`, `HEX()` returns a hexadecimal string representation of `str` where each byte of each character in `str` is converted to two hexadecimal digits. (Multibyte characters therefore become more than two digits.) The inverse of this operation is performed by the `UNHEX()` function.

For a numeric argument `N`, `HEX()` returns a hexadecimal string representation of the value of `N` treated as a longlong (`BIGINT`) number. This is equivalent to `CONV(N, 10, 16)`. The inverse of this operation is performed by `CONV(HEX(N), 16, 10)`.

```
mysql> SELECT X'616263', HEX('abc'), UNHEX(HEX('abc'));
-> 'abc', 616263, 'abc'
mysql> SELECT HEX(255), CONV(HEX(255), 16, 10);
```

```
-> 'FF', 255
```

- `INSERT(str,pos,len,newstr)`

Returns the string *str*, with the substring beginning at position *pos* and *len* characters long replaced by the string *newstr*. Returns the original string if *pos* is not within the length of the string. Replaces the rest of the string from position *pos* if *len* is not within the length of the rest of the string. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT INSERT('Quadratic', 3, 4, 'What');
-> 'QuWhattic'
mysql> SELECT INSERT('Quadratic', -1, 4, 'What');
-> 'Quadratic'
mysql> SELECT INSERT('Quadratic', 3, 100, 'What');
-> 'QuWhat'
```

This function is multibyte safe.

- `INSTR(str,substr)`

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

```
mysql> SELECT INSTR('foobarbar', 'bar');
-> 4
mysql> SELECT INSTR('xbar', 'foobar');
-> 0
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- `LCASE(str)`

`LCASE()` is a synonym for `LOWER()`.

`LCASE()` used in a view is rewritten as `LOWER()` when storing the view's definition. (Bug #12844279)

- `LEFT(str,len)`

Returns the leftmost *len* characters from the string *str*, or `NULL` if any argument is `NULL`.

```
mysql> SELECT LEFT('foobarbar', 5);
-> 'fooba'
```

This function is multibyte safe.

- `LENGTH(str)`

Returns the length of the string *str*, measured in bytes. A multibyte character counts as multiple bytes. This means that for a string containing five 2-byte characters, `LENGTH()` returns 10, whereas `CHAR_LENGTH()` returns 5.

```
mysql> SELECT LENGTH('text');
-> 4
```

Note

The `Length()` OpenGIS spatial function is named `ST_Length()` in MySQL.

- `LOAD_FILE(file_name)`

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the `FILE` privilege. The file must be readable by the server and its size less than `max_allowed_packet` bytes. If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be

loaded must be located in that directory. (Prior to MySQL 8.0.17, the file must be readable by all, not just readable by the server.)

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns `NULL`.

The `character_set_filesystem` system variable controls interpretation of file names that are given as literal strings.

```
mysql> UPDATE t
      SET blob_col=LOAD_FILE('/tmp/picture')
      WHERE id=1;
```

- `LOCATE(substr, str)`, `LOCATE(substr, str, pos)`

The first syntax returns the position of the first occurrence of substring `substr` in string `str`. The second syntax returns the position of the first occurrence of substring `substr` in string `str`, starting at position `pos`. Returns 0 if `substr` is not in `str`. Returns `NULL` if any argument is `NULL`.

```
mysql> SELECT LOCATE('bar', 'foobarbar');
-> 4
mysql> SELECT LOCATE('xbar', 'foobar');
-> 0
mysql> SELECT LOCATE('bar', 'foobarbar', 5);
-> 7
```

This function is multibyte safe, and is case-sensitive only if at least one argument is a binary string.

- `LOWER(str)`

Returns the string `str` with all characters changed to lowercase according to the current character set mapping. The default is `utf8mb4`.

```
mysql> SELECT LOWER('QUADRATICALLY');
-> 'quadratically'
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York   | new york                           |
+-----+-----+
```

For collations of Unicode character sets, `LOWER()` and `UPPER()` work according to the Unicode Collation Algorithm (UCA) version in the collation name, if there is one, and UCA 4.0.0 if no version is specified. For example, `utf8mb4_0900_ai_ci` and `utf8_unicode_520_ci` work according to UCA 9.0.0 and 5.2.0, respectively, whereas `utf8_unicode_ci` works according to UCA 4.0.0. See [Section 10.10.1, “Unicode Character Sets”](#).

This function is multibyte safe.

`LCASE()` used within views is rewritten as `LOWER()`.

- `LPAD(str, len, padstr)`

Returns the string `str`, left-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT LPAD('hi', 4, '??');
-> '??hi'
```

```
mysql> SELECT LPAD('hi',1,'??');
-> 'h'
```

- `LTRIM(str)`

Returns the string *str* with leading space characters removed.

```
mysql> SELECT LTRIM(' barbar');
-> 'barbar'
```

This function is multibyte safe.

- `MAKE_SET(bits,str1,str2,...)`

Returns a set value (a string containing substrings separated by , characters) consisting of the strings that have the corresponding bit in *bits* set. *str1* corresponds to bit 0, *str2* to bit 1, and so on. `NULL` values in *str1*, *str2*, ... are not appended to the result.

```
mysql> SELECT MAKE_SET(1,'a','b','c');
-> 'a'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice','world');
-> 'hello,world'
mysql> SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
-> 'hello'
mysql> SELECT MAKE_SET(0,'a','b','c');
-> ''
```

- `MID(str,pos,len)`

`MID(str,pos,len)` is a synonym for `SUBSTRING(str,pos,len)`.

- `OCT(N)`

Returns a string representation of the octal value of *N*, where *N* is a longlong (`BIGINT`) number. This is equivalent to `CONV(N,10,8)`. Returns `NULL` if *N* is `NULL`.

```
mysql> SELECT OCT(12);
-> '14'
```

- `OCTET_LENGTH(str)`

`OCTET_LENGTH()` is a synonym for `LENGTH()`.

- `ORD(str)`

If the leftmost character of the string *str* is a multibyte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
(1st byte code)
+ (2nd byte code * 256)
+ (3rd byte code * 256^2) ...
```

If the leftmost character is not a multibyte character, `ORD()` returns the same value as the `ASCII()` function.

```
mysql> SELECT ORD('2');
-> 50
```

- `POSITION(substr IN str)`

`POSITION(substr IN str)` is a synonym for `LOCATE(substr,str)`.

- `QUOTE(str)`

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotation marks and with each instance of

backslash (\), single quote ('), ASCII `NUL`, and Control+Z preceded by a backslash. If the argument is `NULL`, the return value is the word “NULL” without enclosing single quotation marks.

```
mysql> SELECT QUOTE('Don\'t!');
-> 'Don\'t!'
mysql> SELECT QUOTE(NULL);
-> NULL
```

For comparison, see the quoting rules for literal strings and within the C API in [Section 9.1.1, “String Literals”](#), and `mysql_real_escape_string_quote()`.

- `REPEAT(str, count)`

Returns a string consisting of the string `str` repeated `count` times. If `count` is less than 1, returns an empty string. Returns `NULL` if `str` or `count` are `NULL`.

```
mysql> SELECT REPEAT('MySQL', 3);
-> 'MySQLMySQLMySQL'
```

- `REPLACE(str, from_str, to_str)`

Returns the string `str` with all occurrences of the string `from_str` replaced by the string `to_str`. `REPLACE()` performs a case-sensitive match when searching for `from_str`.

```
mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

This function is multibyte safe.

- `REVERSE(str)`

Returns the string `str` with the order of the characters reversed.

```
mysql> SELECT REVERSE('abc');
-> 'cba'
```

This function is multibyte safe.

- `RIGHT(str, len)`

Returns the rightmost `len` characters from the string `str`, or `NULL` if any argument is `NULL`.

```
mysql> SELECT RIGHT('foobarbar', 4);
-> 'rbar'
```

This function is multibyte safe.

- `RPAD(str, len, padstr)`

Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters.

```
mysql> SELECT RPAD('hi', 5, '?');
-> 'hi???'
mysql> SELECT RPAD('hi', 1, '?');
-> 'h'
```

This function is multibyte safe.

- `RTRIM(str)`

Returns the string `str` with trailing space characters removed.

```
mysql> SELECT RTRIM('barbar ');
```

```
-> 'barbar'
```

This function is multibyte safe.

- `SOUNDEX(str)`

Returns a soundex string from `str`. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All nonalphabetic characters in `str` are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

Important

When using `SOUNDEX()`, you should be aware of the following limitations:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reliable results.
- This function is not guaranteed to provide consistent results with strings that use multibyte character sets, including `utf-8`. See Bug #22638 for more information.

```
mysql> SELECT SOUNDEX('Hello');
-> 'H400'
mysql> SELECT SOUNDEX('Quadratically');
-> 'Q36324'
```

Note

This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

- `expr1 SOUNDS LIKE expr2`

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)`.

- `SPACE(N)`

Returns a string consisting of `N` space characters.

```
mysql> SELECT SPACE(6);
-> '      '
```

- `SUBSTR(str,pos), SUBSTR(str FROM pos), SUBSTR(str,pos,len), SUBSTR(str FROM pos FOR len)`

`SUBSTR()` is a synonym for `SUBSTRING()`.

- `SUBSTRING(str,pos), SUBSTRING(str FROM pos), SUBSTRING(str,pos,len), SUBSTRING(str FROM pos FOR len)`

The forms without a `len` argument return a substring from string `str` starting at position `pos`. The forms with a `len` argument return a substring `len` characters long from string `str`, starting at position `pos`. The forms that use `FROM` are standard SQL syntax. It is also possible to use a negative value for `pos`. In this case, the beginning of the substring is `pos` characters from the end of the

string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function. A value of 0 for *pos* returns an empty string.

For all forms of `SUBSTRING()`, the position of the first character in the string from which the substring is to be extracted is reckoned as 1.

```
mysql> SELECT SUBSTRING('Quadratically',5);
-> 'ratically'
mysql> SELECT SUBSTRING('foobarbar' FROM 4);
-> 'barbar'
mysql> SELECT SUBSTRING('Quadratically',5,6);
-> 'ratica'
mysql> SELECT SUBSTRING('Sakila', -3);
-> 'ila'
mysql> SELECT SUBSTRING('Sakila', -5, 3);
-> 'aki'
mysql> SELECT SUBSTRING('Sakila' FROM -4 FOR 2);
-> 'ki'
```

This function is multibyte safe.

If *len* is less than 1, the result is the empty string.

- `SUBSTRING_INDEX(str, delim, count)`

Returns the substring from string *str* before *count* occurrences of the delimiter *delim*. If *count* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *count* is negative, everything to the right of the final delimiter (counting from the right) is returned. `SUBSTRING_INDEX()` performs a case-sensitive match when searching for *delim*.

```
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', 2);
-> 'www.mysql'
mysql> SELECT SUBSTRING_INDEX('www.mysql.com', '.', -2);
-> 'mysql.com'
```

This function is multibyte safe.

- `TO_BASE64(str)`

Converts the string argument to base-64 encoded form and returns the result as a character string with the connection character set and collation. If the argument is not a string, it is converted to a string before conversion takes place. The result is `NULL` if the argument is `NULL`. Base-64 encoded strings can be decoded using the `FROM_BASE64()` function.

```
mysql> SELECT TO_BASE64('abc'), FROM_BASE64(TO_BASE64('abc'));
-> 'JWJj', 'abc'
```

Different base-64 encoding schemes exist. These are the encoding and decoding rules used by `TO_BASE64()` and `FROM_BASE64()`:

- The encoding for alphabet value 62 is '+'.
- The encoding for alphabet value 63 is '/'.
- Encoded output consists of groups of 4 printable characters. Each 3 bytes of the input data are encoded using 4 characters. If the last group is incomplete, it is padded with '=' characters to a length of 4.
- A newline is added after each 76 characters of encoded output to divide long output into multiple lines.
- Decoding recognizes and ignores newline, carriage return, tab, and space.
- `TRIM([BOTH | LEADING | TRAILING] [remstr] FROM str), TRIM([remstr] FROM str)`

Returns the string *str* with all *remstr* prefixes or suffixes removed. If none of the specifiers **BOTH**, **LEADING**, or **TRAILING** is given, **BOTH** is assumed. *remstr* is optional and, if not specified, spaces are removed.

```
mysql> SELECT TRIM(' bar ');
-> 'bar'
mysql> SELECT TRIM(LEADING 'x' FROM 'xxxbarxx');
-> 'barxxx'
mysql> SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx');
-> 'bar'
mysql> SELECT TRIM(TRAILING 'xyz' FROM 'barxyz');
-> 'barx'
```

This function is multibyte safe.

- **UCASE(*str*)**

UCASE() is a synonym for **UPPER()**.

UCASE() used within views is rewritten as **UPPER()**.

- **UNHEX(*str*)**

For a string argument *str*, **UNHEX(*str*)** interprets each pair of characters in the argument as a hexadecimal number and converts it to the byte represented by the number. The return value is a binary string.

```
mysql> SELECT UNHEX('4D7953514C');
-> 'MySQL'
mysql> SELECT X'4D7953514C';
-> 'MySQL'
mysql> SELECT UNHEX(HEX('string'));
-> 'string'
mysql> SELECT HEX(UNHEX('1267'));
-> '1267'
```

The characters in the argument string must be legal hexadecimal digits: '0' .. '9', 'A' .. 'F', 'a' .. 'f'. If the argument contains any nonhexadecimal digits, the result is **NULL**:

```
mysql> SELECT UNHEX('GG');
+-----+
| UNHEX('GG') |
+-----+
| NULL        |
+-----+
```

A **NULL** result can occur if the argument to **UNHEX()** is a **BINARY** column, because values are padded with **0x00** bytes when stored but those bytes are not stripped on retrieval. For example, '41' is stored into a **CHAR(3)** column as '41 ' and retrieved as '41' (with the trailing pad space stripped), so **UNHEX()** for the column value returns **X'41'**. By contrast, '41' is stored into a **BINARY(3)** column as '41\0' and retrieved as '41\0' (with the trailing pad **0x00** byte not stripped). '\0' is not a legal hexadecimal digit, so **UNHEX()** for the column value returns **NULL**.

For a numeric argument *N*, the inverse of **HEX(*N*)** is not performed by **UNHEX()**. Use **CONV(HEX(*N*), 16, 10)** instead. See the description of **HEX()**.

- **UPPER(*str*)**

Returns the string *str* with all characters changed to uppercase according to the current character set mapping. The default is **utf8mb4**.

```
mysql> SELECT UPPER('Hej');
```

```
-> 'HEJ'
```

See the description of [LOWER\(\)](#) for information that also applies to [UPPER\(\)](#). This included information about how to perform lettercase conversion of binary strings ([BINARY](#), [VARBINARY](#), [BLOB](#)) for which these functions are ineffective, and information about case folding for Unicode character sets.

This function is multibyte safe.

[UCASE\(\)](#) used within views is rewritten as [UPPER\(\)](#).

- [WEIGHT_STRING\(str \[AS {CHAR|BINARY}\(N\)\] \[flags\]\)](#)

This function returns the weight string for the input string. The return value is a binary string that represents the comparison and sorting value of the string. It has these properties:

- If [WEIGHT_STRING\(str1\)](#) = [WEIGHT_STRING\(str2\)](#), then *str1* = *str2* (*str1* and *str2* are considered equal)
- If [WEIGHT_STRING\(str1\)](#) < [WEIGHT_STRING\(str2\)](#), then *str1* < *str2* (*str1* sorts before *str2*)

[WEIGHT_STRING\(\)](#) is a debugging function intended for internal use. Its behavior can change without notice between MySQL versions. It can be used for testing and debugging of collations, especially if you are adding a new collation. See [Section 10.14, “Adding a Collation to a Character Set”](#).

This list briefly summarizes the arguments. More details are given in the discussion following the list.

- *str*: The input string expression.
- *AS* clause: Optional; cast the input string to a given type and length.
- *flags*: Optional; unused.

The input string, *str*, is a string expression. If the input is a nonbinary (character) string such as a [CHAR](#), [VARCHAR](#), or [TEXT](#) value, the return value contains the collation weights for the string. If the input is a binary (byte) string such as a [BINARY](#), [VARBINARY](#), or [BLOB](#) value, the return value is the same as the input (the weight for each byte in a binary string is the byte value). If the input is [NULL](#), [WEIGHT_STRING\(\)](#) returns [NULL](#).

Examples:

```
mysql> SET @s = _utf8mb4 'AB' COLLATE utf8mb4_0900_ai_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| AB    | 4142    | 1C471C60                |
+-----+-----+-----+
```

```
mysql> SET @s = _utf8mb4 'ab' COLLATE utf8mb4_0900_ai_ci;
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| ab    | 6162    | 1C471C60                |
+-----+-----+-----+
```

```
mysql> SET @s = CAST('AB' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| AB    | 4142    | 4142                    |
+-----+-----+-----+
```

```

+-----+-----+-----+
mysql> SET @s = CAST('ab' AS BINARY);
mysql> SELECT @s, HEX(@s), HEX(WEIGHT_STRING(@s));
+-----+-----+-----+
| @s    | HEX(@s) | HEX(WEIGHT_STRING(@s)) |
+-----+-----+-----+
| ab    | 6162    | 6162                    |
+-----+-----+-----+

```

The preceding examples use `HEX()` to display the `WEIGHT_STRING()` result. Because the result is a binary value, `HEX()` can be especially useful when the result contains nonprinting values, to display it in printable form:

```

mysql> SET @s = CONVERT(X'C39F' USING utf8) COLLATE utf8_czech_ci;
mysql> SELECT HEX(WEIGHT_STRING(@s));
+-----+
| HEX(WEIGHT_STRING(@s)) |
+-----+
| 0FEA0FEA                |
+-----+

```

For non-`NULL` return values, the data type of the value is `VARBINARY` if its length is within the maximum length for `VARBINARY`, otherwise the data type is `BLOB`.

The `AS` clause may be given to cast the input string to a nonbinary or binary string and to force it to a given length:

- `AS CHAR(N)` casts the string to a nonbinary string and pads it on the right with spaces to a length of `N` characters. `N` must be at least 1. If `N` is less than the length of the input string, the string is truncated to `N` characters. No warning occurs for truncation.
- `AS BINARY(N)` is similar but casts the string to a binary string, `N` is measured in bytes (not characters), and padding uses `0x00` bytes (not spaces).

```

mysql> SET NAMES 'latin1';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 41422020                             |
+-----+
mysql> SET NAMES 'utf8';
mysql> SELECT HEX(WEIGHT_STRING('ab' AS CHAR(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS CHAR(4))) |
+-----+
| 0041004200200020                     |
+-----+

mysql> SELECT HEX(WEIGHT_STRING('ab' AS BINARY(4)));
+-----+
| HEX(WEIGHT_STRING('ab' AS BINARY(4))) |
+-----+
| 61620000                             |
+-----+

```

The `flags` clause currently is unused.

12.8.1 String Comparison Functions and Operators

Table 12.13 String Comparison Functions and Operators

Name	Description
<code>LIKE</code>	Simple pattern matching
<code>NOT LIKE</code>	Negation of simple pattern matching

Name	Description
<code>STRCMP ()</code>	Compare two strings

If a string function is given a binary string as an argument, the resulting string is also a binary string. A number converted to a string is treated as a binary string. This affects only comparisons.

Normally, if any expression in a string comparison is case-sensitive, the comparison is performed in case-sensitive fashion.

- `expr LIKE pat [ESCAPE 'escape_char']`

Pattern matching using an SQL pattern. Returns 1 (TRUE) or 0 (FALSE). If either `expr` or `pat` is NULL, the result is NULL.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column. In the latter case, the column must be defined as one of the MySQL string types (see [Section 11.3, “String Data Types”](#)).

Per the SQL standard, `LIKE` performs matching on a per-character basis, thus it can produce results different from the `=` comparison operator:

```
mysql> SELECT 'ä' LIKE 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' LIKE 'ae' COLLATE latin1_german2_ci |
+-----+
|                                         0 |
+-----+
mysql> SELECT 'ä' = 'ae' COLLATE latin1_german2_ci;
+-----+
| 'ä' = 'ae' COLLATE latin1_german2_ci |
+-----+
|                                         1 |
+-----+
```

In particular, trailing spaces are always significant. This differs from comparisons performed with the `=` operator, for which the significance of trailing spaces in nonbinary strings (`CHAR`, `VARCHAR`, and `TEXT` values) depends on the pad attribute of the the collation used for the comparison. For more information, see [Trailing Space Handling in Comparisons](#).

With `LIKE` you can use the following two wildcard characters in the pattern:

- `%` matches any number of characters, even zero characters.
- `_` matches exactly one character.

```
mysql> SELECT 'David!' LIKE 'David_';
-> 1
mysql> SELECT 'David!' LIKE '%D%v%';
-> 1
```

To test for literal instances of a wildcard character, precede it by the escape character. If you do not specify the `ESCAPE` character, `\` is assumed.

- `\%` matches one `%` character.
- `_` matches one `_` character.

```
mysql> SELECT 'David!' LIKE 'David\_';
-> 0
mysql> SELECT 'David_' LIKE 'David\_';
-> 1
```

To specify a different escape character, use the `ESCAPE` clause:

```
mysql> SELECT 'David_' LIKE 'David|_' ESCAPE '|';
-> 1
```

The escape sequence should be empty or one character long. The expression must evaluate as a constant at execution time. If the `NO_BACKSLASH_ESCAPES` SQL mode is enabled, the sequence cannot be empty.

The following two statements illustrate that string comparisons are not case-sensitive unless one of the operands is case-sensitive (uses a case-sensitive collation or is a binary string):

```
mysql> SELECT 'abc' LIKE 'ABC';
-> 1
mysql> SELECT 'abc' LIKE _utf8mb4 'ABC' COLLATE utf8mb4_0900_as_cs;
-> 0
mysql> SELECT 'abc' LIKE _utf8mb4 'ABC' COLLATE utf8mb4_bin;
-> 0
mysql> SELECT 'abc' LIKE BINARY 'ABC';
-> 0
```

As an extension to standard SQL, MySQL permits `LIKE` on numeric expressions.

```
mysql> SELECT 10 LIKE '1%';
-> 1
```

Note

Because MySQL uses C escape syntax in strings (for example, `\n` to represent a newline character), you must double any `\` that you use in `LIKE` strings. For example, to search for `\n`, specify it as `\\n`. To search for `\`, specify it as `\\\\`; this is because the backslashes are stripped once by the parser and again when the pattern match is made, leaving a single backslash to be matched against.

Exception: At the end of the pattern string, backslash can be specified as `\\`. At the end of the string, backslash stands for itself because there is nothing following to escape. Suppose that a table contains the following values:

```
mysql> SELECT filename FROM t1;
+-----+
| filename |
+-----+
| C:       |
| C:\      |
| C:\Programs |
| C:\Programs\ |
+-----+
```

To test for values that end with backslash, you can match the values using either of the following patterns:

```
mysql> SELECT filename, filename LIKE '%\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\' |
+-----+-----+
| C:       | 0 |
| C:\      | 1 |
| C:\Programs | 0 |
| C:\Programs\ | 1 |
+-----+-----+

mysql> SELECT filename, filename LIKE '%\\\\' FROM t1;
+-----+-----+
| filename | filename LIKE '%\\\\' |
+-----+-----+
| C:       | 0 |
| C:\      | 1 |
```

C:\Programs	0
C:\Programs\	1
+-----+	

- `expr NOT LIKE pat [ESCAPE 'escape_char']`

This is the same as `NOT (expr LIKE pat [ESCAPE 'escape_char'])`.

Note

Aggregate queries involving `NOT LIKE` comparisons with columns containing `NULL` may yield unexpected results. For example, consider the following table and data:

```
CREATE TABLE foo (bar VARCHAR(10));
INSERT INTO foo VALUES (NULL), (NULL);
```

The query `SELECT COUNT(*) FROM foo WHERE bar LIKE '%baz%';` returns 0. You might assume that `SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%';` would return 2. However, this is not the case: The second query returns 0. This is because `NULL NOT LIKE expr` always returns `NULL`, regardless of the value of `expr`. The same is true for aggregate queries involving `NULL` and comparisons using `NOT RLIKE` or `NOT REGEXP`. In such cases, you must test explicitly for `NOT NULL` using `OR` (and not `AND`), as shown here:

```
SELECT COUNT(*) FROM foo WHERE bar NOT LIKE '%baz%' OR bar IS NULL;
```

- `STRCMP(expr1,expr2)`

`STRCMP()` returns 0 if the strings are the same, -1 if the first argument is smaller than the second according to the current sort order, and 1 otherwise.

```
mysql> SELECT STRCMP('text', 'text2');
-> -1
mysql> SELECT STRCMP('text2', 'text');
-> 1
mysql> SELECT STRCMP('text', 'text');
-> 0
```

`STRCMP()` performs the comparison using the collation of the arguments.

```
mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
mysql> SELECT STRCMP(@s1, @s2), STRCMP(@s3, @s4);
+-----+-----+
| STRCMP(@s1, @s2) | STRCMP(@s3, @s4) |
+-----+-----+
| 0 | -1 |
+-----+-----+
```

If the collations are incompatible, one of the arguments must be converted to be compatible with the other. See [Section 10.8.4, “Collation Coercibility in Expressions”](#).

```
mysql> SET @s1 = _utf8mb4 'x' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s2 = _utf8mb4 'X' COLLATE utf8mb4_0900_ai_ci;
mysql> SET @s3 = _utf8mb4 'x' COLLATE utf8mb4_0900_as_cs;
mysql> SET @s4 = _utf8mb4 'X' COLLATE utf8mb4_0900_as_cs;
-->
mysql> SELECT STRCMP(@s1, @s3);
ERROR 1267 (HY000): Illegal mix of collations (utf8mb4_0900_ai_ci,IMPLICIT)
and (utf8mb4_0900_as_cs,IMPLICIT) for operation 'strcmp'
mysql> SELECT STRCMP(@s1, @s3 COLLATE utf8mb4_0900_ai_ci);
+-----+
```

```
| STRCMP(@s1, @s3 COLLATE utf8mb4_0900_ai_ci) |
+-----+
|                                     0 |
+-----+
```

12.8.2 Regular Expressions

Table 12.14 Regular Expression Functions and Operators

Name	Description
<code>NOT REGEXP</code>	Negation of REGEXP
<code>REGEXP</code>	Whether string matches regular expression
<code>REGEXP_INSTR()</code>	Starting index of substring matching regular expression
<code>REGEXP_LIKE()</code>	Whether string matches regular expression
<code>REGEXP_REPLACE()</code>	Replace substrings matching regular expression
<code>REGEXP_SUBSTR()</code>	Return substring matching regular expression
<code>RLIKE</code>	Whether string matches regular expression

A regular expression is a powerful way of specifying a pattern for a complex search. This section discusses the functions and operators available for regular expression matching and illustrates, with examples, some of the special characters and constructs that can be used for regular expression operations. See also [Section 3.3.4.7, “Pattern Matching”](#).

MySQL implements regular expression support using International Components for Unicode (ICU), which provides full Unicode support and is multibyte safe. (Prior to MySQL 8.0.4, MySQL used Henry Spencer's implementation of regular expressions, which operates in byte-wise fashion and is not multibyte safe. For information about ways in which applications that use regular expressions may be affected by the implementation change, see [Regular Expression Compatibility Considerations](#).)

- [Regular Expression Functions and Operators](#)
- [Regular Expression Syntax](#)
- [Regular Expression Resource Control](#)
- [Regular Expression Compatibility Considerations](#)

Regular Expression Functions and Operators

- `expr NOT REGEXP pat, expr NOT RLIKE pat`

This is the same as `NOT (expr REGEXP pat)`.

- `expr REGEXP pat, expr RLIKE pat`

Returns 1 if the string `expr` matches the regular expression specified by the pattern `pat`, 0 otherwise. If `expr` or `pat` is `NULL`, the return value is `NULL`.

`REGEXP` and `RLIKE` are synonyms for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT 'Michael!' REGEXP '.*';
+-----+
| 'Michael!' REGEXP '.*' |
+-----+
|                        1 |
+-----+
mysql> SELECT 'new*\n*line' REGEXP 'new\\*\\.\\*line';
+-----+
```

```

+-----+
| 'new*\n*line' REGEXP 'new\\*.*\\*line' |
+-----+
|                                     0 |
+-----+
mysql> SELECT 'a' REGEXP '^[a-d]';
+-----+
| 'a' REGEXP '^[a-d]' |
+-----+
|                   1 |
+-----+
mysql> SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
+-----+
| 'a' REGEXP 'A' | 'a' REGEXP BINARY 'A' |
+-----+
|               1 |                0 |
+-----+

```

- `REGEXP_INSTR(expr, pat[, pos[, occurrence[, return_option[, match_type]]])`

Returns the starting index of the substring of the string *expr* that matches the regular expression specified by the pattern *pat*, 0 if there is no match. If *expr* or *pat* is `NULL`, the return value is `NULL`. Character indexes begin at 1.

`REGEXP_INSTR()` takes these optional arguments:

- *pos*: The position in *expr* at which to start the search. If omitted, the default is 1.
- *occurrence*: Which occurrence of a match to search for. If omitted, the default is 1.
- *return_option*: Which type of position to return. If this value is 0, `REGEXP_INSTR()` returns the position of the matched substring's first character. If this value is 1, `REGEXP_INSTR()` returns the position following the matched substring. If omitted, the default is 0.
- *match_type*: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```

mysql> SELECT REGEXP_INSTR('dog cat dog', 'dog');
+-----+
| REGEXP_INSTR('dog cat dog', 'dog') |
+-----+
|                   1 |
+-----+
mysql> SELECT REGEXP_INSTR('dog cat dog', 'dog', 2);
+-----+
| REGEXP_INSTR('dog cat dog', 'dog', 2) |
+-----+
|                   9 |
+-----+
mysql> SELECT REGEXP_INSTR('aa aaa aaaa', 'a{2}');
+-----+
| REGEXP_INSTR('aa aaa aaaa', 'a{2}') |
+-----+
|                   1 |
+-----+
mysql> SELECT REGEXP_INSTR('aa aaa aaaa', 'a{4}');
+-----+
| REGEXP_INSTR('aa aaa aaaa', 'a{4}') |
+-----+
|                   8 |
+-----+

```

- `REGEXP_LIKE(expr, pat[, match_type])`

Returns 1 if the string *expr* matches the regular expression specified by the pattern *pat*, 0 otherwise. If *expr* or *pat* is `NULL`, the return value is `NULL`.

The pattern can be an extended regular expression, the syntax for which is discussed in [Regular Expression Syntax](#). The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

The optional *match_type* argument is a string that may contain any or all the following characters specifying how to perform matching:

- **c**: Case-sensitive matching.
- **i**: Case-insensitive matching.
- **m**: Multiple-line mode. Recognize line terminators within the string. The default behavior is to match line terminators only at the start and end of the string expression.
- **n**: The `.` character matches line terminators. The default is for `.` matching to stop at the end of a line.
- **u**: Unix-only line endings. Only the newline character is recognized as a line ending by the `.`, `^`, and `$` match operators.

If characters specifying contradictory options are specified within *match_type*, the rightmost one takes precedence.

By default, regular expression operations use the character set and collation of the *expr* and *pat* arguments when deciding the type of a character and performing the comparison. If the arguments have different character sets or collations, coercibility rules apply as described in [Section 10.8.4, “Collation Coercibility in Expressions”](#). Arguments may be specified with explicit collation indicators to change comparison behavior.

```
mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE');
+-----+
| REGEXP_LIKE('CamelCase', 'CAMELCASE') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs);
+-----+
| REGEXP_LIKE('CamelCase', 'CAMELCASE' COLLATE utf8mb4_0900_as_cs) |
+-----+
| 0 |
+-----+
```

match_type may be specified with the **c** or **i** characters to override the default case sensitivity. Exception: If either argument is a binary string, the arguments are handled in case-sensitive fashion as binary strings, even if *match_type* contains the **i** character.

Note

Because MySQL uses the C escape syntax in strings (for example, `\n` to represent the newline character), you must double any `\` that you use in your *expr* and *pat* arguments.

```
mysql> SELECT REGEXP_LIKE('Michael!', '.*');
+-----+
| REGEXP_LIKE('Michael!', '.*') |
+-----+
| 1 |
+-----+
mysql> SELECT REGEXP_LIKE('new\n*line', 'new\\*\\.\\*line');
+-----+
| REGEXP_LIKE('new\n*line', 'new\\*\\.\\*line') |
+-----+
| 0 |
+-----+
```

```
mysql> SELECT REGEXP_LIKE('a', '^[a-d]');
+-----+
| REGEXP_LIKE('a', '^[a-d]') |
+-----+
| 1 |
+-----+

mysql> SELECT REGEXP_LIKE('a', 'A'), REGEXP_LIKE('a', BINARY 'A');
+-----+-----+
| REGEXP_LIKE('a', 'A') | REGEXP_LIKE('a', BINARY 'A') |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

```
mysql> SELECT REGEXP_LIKE('abc', 'ABC');
+-----+
| REGEXP_LIKE('abc', 'ABC') |
+-----+
| 1 |
+-----+

mysql> SELECT REGEXP_LIKE('abc', 'ABC', 'c');
+-----+
| REGEXP_LIKE('abc', 'ABC', 'c') |
+-----+
| 0 |
+-----+
```

- `REGEXP_REPLACE(expr, pat, repl[, pos[, occurrence[, match_type]])`

Replaces occurrences in the string *expr* that match the regular expression specified by the pattern *pat* with the replacement string *repl*, and returns the resulting string. If *expr*, *pat*, or *repl* is `NULL`, the return value is `NULL`.

`REGEXP_REPLACE()` takes these optional arguments:

- *pos*: The position in *expr* at which to start the search. If omitted, the default is 1.
- *occurrence*: Which occurrence of a match to replace. If omitted, the default is 0 (which means “replace all occurrences”).
- *match_type*: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

Prior to MySQL 8.0.17, the result returned by this function used the `UTF-16` character set; in MySQL 8.0.17 and later, the character set and collation of the expression searched for matches is used. (Bug #94203, Bug #29308212)

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT REGEXP_REPLACE('a b c', 'b', 'X');
+-----+
| REGEXP_REPLACE('a b c', 'b', 'X') |
+-----+
| a X c |
+-----+

mysql> SELECT REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3);
+-----+
| REGEXP_REPLACE('abc def ghi', '[a-z]+', 'X', 1, 3) |
+-----+
| abc def X |
+-----+
```

- `REGEXP_SUBSTR(expr, pat[, pos[, occurrence[, match_type]])`

Returns the substring of the string `expr` that matches the regular expression specified by the pattern `pat`, `NULL` if there is no match. If `expr` or `pat` is `NULL`, the return value is `NULL`.

`REGEXP_SUBSTR()` takes these optional arguments:

- `pos`: The position in `expr` at which to start the search. If omitted, the default is 1.
- `occurrence`: Which occurrence of a match to search for. If omitted, the default is 1.
- `match_type`: A string that specifies how to perform matching. The meaning is as described for `REGEXP_LIKE()`.

Prior to MySQL 8.0.17, the result returned by this function used the `UTF-16` character set; in MySQL 8.0.17 and later, the character set and collation of the expression searched for matches is used. (Bug #94203, Bug #29308212)

For additional information about how matching occurs, see the description for `REGEXP_LIKE()`.

```
mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+');
+-----+
| REGEXP_SUBSTR('abc def ghi', '[a-z]+') |
+-----+
| abc                                     |
+-----+
mysql> SELECT REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3);
+-----+
| REGEXP_SUBSTR('abc def ghi', '[a-z]+', 1, 3) |
+-----+
| ghi                                         |
+-----+
```

Regular Expression Syntax

A regular expression describes a set of strings. The simplest regular expression is one that has no special characters in it. For example, the regular expression `hello` matches `hello` and nothing else.

Nontrivial regular expressions use certain special constructs so that they can match more than one string. For example, the regular expression `hello|world` contains the `|` alternation operator and matches either the `hello` or `world`.

As a more complex example, the regular expression `B[an]*s` matches any of the strings `Bananas`, `Baaaaas`, `Bs`, and any other string starting with a `B`, ending with an `s`, and containing any number of `a` or `n` characters in between.

The following list covers some of the basic special characters and constructs that can be used in regular expressions. For information about the full regular expression syntax supported by the ICU library used to implement regular expression support, visit the [International Components for Unicode website](#).

- `^`

Match the beginning of a string.

```
mysql> SELECT REGEXP_LIKE('fo\ngo', '^fo$');      -> 0
mysql> SELECT REGEXP_LIKE('fofo', '^fo');        -> 1
```

- `$`

Match the end of a string.

```
mysql> SELECT REGEXP_LIKE('fo\ngo', '^fo\ngo$');  -> 1
mysql> SELECT REGEXP_LIKE('fo\ngo', '^fo$');      -> 0
```

- .

Match any character (including carriage return and newline, although to match these in the middle of a string, the `m` (multiple line) match-control character or the `(?m)` within-pattern modifier must be given).

```
mysql> SELECT REGEXP_LIKE('fofo', '^f.*$');          -> 1
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '^f.*$');      -> 0
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '^f.*$', 'm');  -> 1
mysql> SELECT REGEXP_LIKE('fo\r\nfo', '(?m)^f.*$');  -> 1
```

- a*

Match any sequence of zero or more `a` characters.

```
mysql> SELECT REGEXP_LIKE('Ban', '^Ba*n');          -> 1
mysql> SELECT REGEXP_LIKE('Baaan', '^Ba*n');        -> 1
mysql> SELECT REGEXP_LIKE('Bn', '^Ba*n');           -> 1
```

- a+

Match any sequence of one or more `a` characters.

```
mysql> SELECT REGEXP_LIKE('Ban', '^Ba+n');          -> 1
mysql> SELECT REGEXP_LIKE('Bn', '^Ba+n');           -> 0
```

- a?

Match either zero or one `a` character.

```
mysql> SELECT REGEXP_LIKE('Bn', '^Ba?n');           -> 1
mysql> SELECT REGEXP_LIKE('Ban', '^Ba?n');          -> 1
mysql> SELECT REGEXP_LIKE('Baan', '^Ba?n');         -> 0
```

- de|abc

Alternation; match either of the sequences `de` or `abc`.

```
mysql> SELECT REGEXP_LIKE('pi', 'pi|apa');          -> 1
mysql> SELECT REGEXP_LIKE('axe', 'pi|apa');         -> 0
mysql> SELECT REGEXP_LIKE('apa', 'pi|apa');         -> 1
mysql> SELECT REGEXP_LIKE('apa', '^(pi|apa)$');      -> 1
mysql> SELECT REGEXP_LIKE('pi', '^(pi|apa)$');      -> 1
mysql> SELECT REGEXP_LIKE('pix', '^(pi|apa)$');     -> 0
```

- (abc)*

Match zero or more instances of the sequence `abc`.

```
mysql> SELECT REGEXP_LIKE('pi', '^(pi)*$');         -> 1
mysql> SELECT REGEXP_LIKE('pip', '^(pi)*$');        -> 0
mysql> SELECT REGEXP_LIKE('pipi', '^(pi)*$');       -> 1
```

- {1}, {2,3}

Repetition; `{n}` and `{m,n}` notation provide a more general way of writing regular expressions that match many occurrences of the previous atom (or “piece”) of the pattern. `m` and `n` are integers.

- a*

Can be written as `a{0,}`.

- a+

Can be written as `a{1,}`.

- a?

Can be written as `a{0,1}`.

To be more precise, `a{n}` matches exactly *n* instances of *a*. `a{n,}` matches *n* or more instances of *a*. `a{m,n}` matches *m* through *n* instances of *a*, inclusive. If both *m* and *n* are given, *m* must be less than or equal to *n*.

```
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{2}e');          -> 0
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{3}e');          -> 1
mysql> SELECT REGEXP_LIKE('abcde', 'a[bcd]{1,10}e');        -> 1
```

- `[a-dX]`, `[^a-dX]`

Matches any character that is (or is not, if `^` is used) either *a*, *b*, *c*, *d* or *X*. A `-` character between two other characters forms a range that matches all characters from the first character to the second. For example, `[0-9]` matches any decimal digit. To include a literal `]` character, it must immediately follow the opening bracket `[`. To include a literal `-` character, it must be written first or last. Any character that does not have a defined special meaning inside a `[]` pair matches only itself.

```
mysql> SELECT REGEXP_LIKE('aXbc', '[a-dXYZ]');            -> 1
mysql> SELECT REGEXP_LIKE('aXbc', '[^a-dXYZ]$');           -> 0
mysql> SELECT REGEXP_LIKE('aXbc', '[^a-dXYZ]+$');          -> 1
mysql> SELECT REGEXP_LIKE('aXbc', '[^a-dXYZ]+$');          -> 0
mysql> SELECT REGEXP_LIKE('gheis', '[^a-dXYZ]+$');         -> 1
mysql> SELECT REGEXP_LIKE('gheisa', '[^a-dXYZ]+$');        -> 0
```

- `[=character_class=]`

Within a bracket expression (written using `[` and `]`), `[=character_class=]` represents an equivalence class. It matches all characters with the same collation value, including itself. For example, if `o` and `(+)` are the members of an equivalence class, `[[=o=]]`, `[[= (+)=]]`, and `[o(+)]` are all synonymous. An equivalence class may not be used as an endpoint of a range.

- `[:character_class:]`

Within a bracket expression (written using `[` and `]`), `[:character_class:]` represents a character class that matches all characters belonging to that class. The following table lists the standard class names. These names stand for the character classes defined in the `ctype(3)` manual page. A particular locale may provide other class names. A character class may not be used as an endpoint of a range.

Character Class Name	Meaning
<code>alnum</code>	Alphanumeric characters
<code>alpha</code>	Alphabetic characters
<code>blank</code>	Whitespace characters
<code>cntrl</code>	Control characters
<code>digit</code>	Digit characters
<code>graph</code>	Graphic characters
<code>lower</code>	Lowercase alphabetic characters
<code>print</code>	Graphic or space characters
<code>punct</code>	Punctuation characters
<code>space</code>	Space, tab, newline, and carriage return
<code>upper</code>	Uppercase alphabetic characters
<code>xdigit</code>	Hexadecimal digit characters

```
mysql> SELECT REGEXP_LIKE('justalnums', '[:alnum:]+');     -> 1
```

```
mysql> SELECT REGEXP_LIKE('!', '[:alnum:]+');          -> 0
```

To use a literal instance of a special character in a regular expression, precede it by two backslash (\) characters. The MySQL parser interprets one of the backslashes, and the regular expression library interprets the other. For example, to match the string `1+2` that contains the special `+` character, only the last of the following regular expressions is the correct one:

```
mysql> SELECT REGEXP_LIKE('1+2', '1+2');              -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\+2');             -> 0
mysql> SELECT REGEXP_LIKE('1+2', '1\\+2');            -> 1
```

Regular Expression Resource Control

`REGEXP_LIKE()` and similar functions use resources that can be controlled by setting system variables:

- The match engine uses memory for its internal stack. To control the maximum available memory for the stack in bytes, set the `regex_stack_limit` system variable.
- The match engine operates in steps. To control the maximum number of steps performed by the engine (and thus indirectly the execution time), set the `regex_time_limit` system variable. Because this limit is expressed as number of steps, it affects execution time only indirectly. Typically, it is on the order of milliseconds.

Regular Expression Compatibility Considerations

Prior to MySQL 8.0.4, MySQL used the Henry Spencer regular expression library to support regular expression operations, rather than International Components for Unicode (ICU). The following discussion describes differences between the Spencer and ICU libraries that may affect applications:

- With the Spencer library, the `REGEXP` and `RLIKE` operators work in byte-wise fashion, so they are not multibyte safe and may produce unexpected results with multibyte character sets. In addition, these operators compare characters by their byte values and accented characters may not compare as equal even if a given collation treats them as equal.

ICU has full Unicode support and is multibyte safe. Its regular expression functions treat all strings as `UTF-16`. You should keep in mind that positional indexes are based on 16-bit chunks and not on code points. This means that, when passed to such functions, characters using more than one chunk may produce unanticipated results, such as those shown here:

```
mysql> SELECT REGEXP_INSTR('𐀀', 'b');
+-----+
| REGEXP_INSTR('??b', 'b') |
+-----+
| 5 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('𐀀xxx', 'b', 4);
+-----+
| REGEXP_INSTR('??bxxx', 'b', 4) |
+-----+
| 5 |
+-----+
1 row in set (0.00 sec)
```

Characters within the Unicode Basic Multilingual Plane, which includes characters used by most modern languages, are safe in this regard:

```
mysql> SELECT REGEXP_INSTR('ᐃᐃb', 'b');
+-----+
| REGEXP_INSTR('ᐃᐃb', 'b') |
+-----+
| 3 |
+-----+
```

```

1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('בּב', 'ב');
+-----+
| REGEXP_INSTR('בּב', 'ב') |
+-----+
| 3 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_INSTR('בּבב', 'ב');
+-----+
| REGEXP_INSTR('בּבב', 'ב') |
+-----+
| 3 |
+-----+
1 row in set (0.00 sec)

```

Emoji, such as the “sushi” character `#U+1F363`) used in the first two examples, are not included in the Basic Multilingual Plane, but rather in Unicode’s Supplementary Multilingual Plane. Another issue can arise with emoji and other 4-byte characters when `REGEXP_SUBSTR()` or a similar function begins searching in the middle of a character. Each of the two statements in the following example starts from the second 2-byte position in the first argument. The first statement works on a string consisting solely of 2-byte (BMP) characters. The second statement contains 4-byte characters which are incorrectly interpreted in the result because the first two bytes are stripped off and so the remainder of the character data is misaligned.

```

mysql> SELECT REGEXP_SUBSTR('周周周周', '.*', 2);
+-----+
| REGEXP_SUBSTR('周周周周', '.*', 2) |
+-----+
| 周周周 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT REGEXP_SUBSTR('𠂇𠂇𠂇𠂇', '.*', 2);
+-----+
| REGEXP_SUBSTR('𠂇𠂇𠂇𠂇', '.*', 2) |
+-----+
| 𠂇𠂇𠂇 |
+-----+
1 row in set (0.00 sec)

```

- For the `.` operator, the Spencer library matches line-terminator characters (carriage return, newline) anywhere in string expressions, including in the middle. To match line terminator characters in the middle of strings with ICU, specify the `m` match-control character.
- The Spencer library supports word-beginning and word-end boundary markers (`[[:<:]]` and `[[:>:]]` notation). ICU does not. For ICU, you can use `\b` to match word boundaries; double the backslash because MySQL interprets it as the escape character within strings.
- The Spencer library supports collating element bracket expressions (`[.characters.]` notation). ICU does not.
- For repetition counts (`{n}` and `{m,n}` notation), the Spencer library has a maximum of 255. ICU has no such limit, although the maximum number of match engine steps can be limited by setting the `regexp_time_limit` system variable.
- ICU interprets parentheses as metacharacters. To specify a literal open or close parenthesis `(` in a regular expression, it must be escaped:

```

mysql> SELECT REGEXP_LIKE('(', '(');
ERROR 3692 (HY000): Mismatched parenthesis in regular expression.
mysql> SELECT REGEXP_LIKE('(', '\\(');
+-----+
| REGEXP_LIKE('(', '\\(') |
+-----+

```

```

+-----+
|          1 |
+-----+
mysql> SELECT REGEXP_LIKE(')', '');
ERROR 3692 (HY000): Mismatched parenthesis in regular expression.
mysql> SELECT REGEXP_LIKE(')', '\\\');
+-----+
| REGEXP_LIKE(')', '\\\') |
+-----+
|          1 |
+-----+

```

- ICU also interprets square brackets as metacharacters, but only the opening square bracket need be escaped to be used as a literal character:

```

mysql> SELECT REGEXP_LIKE('[', '[');
ERROR 3696 (HY000): The regular expression contains an
unclosed bracket expression.
mysql> SELECT REGEXP_LIKE('[', '\\[');
+-----+
| REGEXP_LIKE('[', '\\[') |
+-----+
|          1 |
+-----+
mysql> SELECT REGEXP_LIKE(']', ']');
+-----+
| REGEXP_LIKE(']', ']') |
+-----+
|          1 |
+-----+

```

12.8.3 Character Set and Collation of Function Results

MySQL has many operators and functions that return a string. This section answers the question: What is the character set and collation of such a string?

For simple functions that take string input and return a string result as output, the output's character set and collation are the same as those of the principal input value. For example, `UPPER(X)` returns a string with the same character string and collation as `X`. The same applies for `INSTR()`, `LCASE()`, `LOWER()`, `LTRIM()`, `MID()`, `REPEAT()`, `REPLACE()`, `REVERSE()`, `RIGHT()`, `RPAD()`, `RTRIM()`, `SOUNDEX()`, `SUBSTRING()`, `TRIM()`, `UCASE()`, and `UPPER()`.

Note

The `REPLACE()` function, unlike all other functions, always ignores the collation of the string input and performs a case-sensitive comparison.

If a string input or function result is a binary string, the string has the `binary` character set and collation. This can be checked by using the `CHARSET()` and `COLLATION()` functions, both of which return `binary` for a binary string argument:

```

mysql> SELECT CHARSET(BINARY 'a'), COLLATION(BINARY 'a');
+-----+-----+
| CHARSET(BINARY 'a') | COLLATION(BINARY 'a') |
+-----+-----+
| binary              | binary                |
+-----+-----+

```

For operations that combine multiple string inputs and return a single string output, the “aggregation rules” of standard SQL apply for determining the collation of the result:

- If an explicit `COLLATE Y` occurs, use `Y`.
- If explicit `COLLATE Y` and `COLLATE Z` occur, raise an error.
- Otherwise, if all collations are `Y`, use `Y`.

- Otherwise, the result has no collation.

For example, with `CASE ... WHEN a THEN b WHEN b THEN c COLLATE X END`, the resulting collation is `X`. The same applies for `UNION`, `||`, `CONCAT()`, `ELT()`, `GREATEST()`, `IF()`, and `LEAST()`.

For operations that convert to character data, the character set and collation of the strings that result from the operations are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see [Section 10.4, “Connection Character Sets and Collations”](#)). This applies only to `BIN_TO_UUID()`, `CAST()`, `CONV()`, `FORMAT()`, `HEX()`, and `SPACE()`.

An exception to the preceding principle occurs for expressions for virtual generated columns. In such expressions, the table character set is used for `BIN_TO_UUID()`, `CONV()`, or `HEX()` results, regardless of connection character set.

If there is any question about the character set or collation of the result returned by a string function, use the `CHARSET()` or `COLLATION()` function to find out:

```
mysql> SELECT USER(), CHARSET(USER()), COLLATION(USER());
+-----+-----+-----+
| USER()          | CHARSET(USER()) | COLLATION(USER()) |
+-----+-----+-----+
| test@localhost  | utf8            | utf8_general_ci   |
+-----+-----+-----+
mysql> SELECT CHARSET(COMPRESS('abc')), COLLATION(COMPRESS('abc'));
+-----+-----+
| CHARSET(COMPRESS('abc')) | COLLATION(COMPRESS('abc')) |
+-----+-----+
| binary                  | binary                     |
+-----+-----+
```

12.9 What Calendar Is Used By MySQL?

MySQL uses what is known as a *proleptic Gregorian calendar*.

Every country that has switched from the Julian to the Gregorian calendar has had to discard at least ten days during the switch. To see how this works, consider the month of October 1582, when the first Julian-to-Gregorian switch occurred.

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
1	2	3	4	15	16	17
18	19	20	21	22	23	24
25	26	27	28	29	30	31

There are no dates between October 4 and October 15. This discontinuity is called the *cutover*. Any dates before the cutover are Julian, and any dates following the cutover are Gregorian. Dates during a cutover are nonexistent.

A calendar applied to dates when it was not actually in use is called *proleptic*. Thus, if we assume there was never a cutover and Gregorian rules always rule, we have a proleptic Gregorian calendar. This is what is used by MySQL, as is required by standard SQL. For this reason, dates prior to the cutover stored as MySQL `DATE` or `DATETIME` values must be adjusted to compensate for the difference. It is important to realize that the cutover did not occur at the same time in all countries, and that the later it happened, the more days were lost. For example, in Great Britain, it took place in 1752, when Wednesday September 2 was followed by Thursday September 14. Russia remained on the Julian calendar until 1918, losing 13 days in the process, and what is popularly referred to as its “October Revolution” occurred in November according to the Gregorian calendar.

12.10 Full-Text Search Functions

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

```
search_modifier:
{
    IN NATURAL LANGUAGE MODE
  | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
  | IN BOOLEAN MODE
  | WITH QUERY EXPANSION
}
```

MySQL has support for full-text indexing and searching:

- A full-text index in MySQL is an index of type `FULLTEXT`.
- Full-text indexes can be used only with `InnoDB` or `MyISAM` tables, and can be created only for `CHAR`, `VARCHAR`, or `TEXT` columns.
- MySQL provides a built-in full-text ngram parser that supports Chinese, Japanese, and Korean (CJK), and an installable MeCab full-text parser plugin for Japanese. Parsing differences are outlined in [Section 12.10.8, “ngram Full-Text Parser”](#), and [Section 12.10.9, “MeCab Full-Text Parser Plugin”](#).
- A `FULLTEXT` index definition can be given in the `CREATE TABLE` statement when a table is created, or added later using `ALTER TABLE` or `CREATE INDEX`.
- For large data sets, it is much faster to load your data into a table that has no `FULLTEXT` index and then create the index after that, than to load data into a table that has an existing `FULLTEXT` index.

Full-text searching is performed using `MATCH() ... AGAINST` syntax. `MATCH()` takes a comma-separated list that names the columns to be searched. `AGAINST` takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.

There are three types of full-text searches:

- A natural language search interprets the search string as a phrase in natural human language (a phrase in free text). There are no special operators, with the exception of double quote (") characters. The stopwords list applies. For more information about stopwords lists, see [Section 12.10.4, “Full-Text Stopwords”](#).

Full-text searches are natural language searches if the `IN NATURAL LANGUAGE MODE` modifier is given or if no modifier is given. For more information, see [Section 12.10.1, “Natural Language Full-Text Searches”](#).

- A boolean search interprets the search string using the rules of a special query language. The string contains the words to search for. It can also contain operators that specify requirements such that a word must be present or absent in matching rows, or that it should be weighted higher or lower than usual. Certain common words (stopwords) are omitted from the search index and do not match if present in the search string. The `IN BOOLEAN MODE` modifier specifies a boolean search. For more information, see [Section 12.10.2, “Boolean Full-Text Searches”](#).
- A query expansion search is a modification of a natural language search. The search string is used to perform a natural language search. Then words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` or `WITH QUERY EXPANSION` modifier specifies a query expansion search. For more information, see [Section 12.10.3, “Full-Text Searches with Query Expansion”](#).

For information about `FULLTEXT` query performance, see [Section 8.3.5, “Column Indexes”](#).

For more information about `InnoDB FULLTEXT` indexes, see [Section 15.6.2.4, “InnoDB FULLTEXT Indexes”](#).

Constraints on full-text searching are listed in [Section 12.10.5, “Full-Text Restrictions”](#).

The `myisam_ftdump` utility dumps the contents of a `MyISAM` full-text index. This may be helpful for debugging full-text queries. See [Section 4.6.3, “myisam_ftdump — Display Full-Text Index information”](#).

12.10.1 Natural Language Full-Text Searches

By default or with the `IN NATURAL LANGUAGE MODE` modifier, the `MATCH()` function performs a natural language search for a string against a *text collection*. A collection is a set of one or more columns included in a `FULLTEXT` index. The search string is given as the argument to `AGAINST()`. For each row in the table, `MATCH()` returns a relevance value; that is, a similarity measure between the search string and the text in that row in the columns named in the `MATCH()` list.

```
mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.08 sec)

mysql> INSERT INTO articles (title,body) VALUES
    ('MySQL Tutorial','DBMS stands for DataBase ...'),
    ('How To Use MySQL Well','After you went through a ...'),
    ('Optimizing MySQL','In this tutorial we will show ...'),
    ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
    ('MySQL vs. YourSQL','In the following database comparison ...'),
    ('MySQL Security','When configured properly, MySQL ...');
Query OK, 6 rows affected (0.01 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM articles
    WHERE MATCH (title,body)
    AGAINST ('database' IN NATURAL LANGUAGE MODE);
+----+-----+-----+
| id | title                | body                |
+----+-----+-----+
|  1 | MySQL Tutorial       | DBMS stands for DataBase ... |
|  5 | MySQL vs. YourSQL    | In the following database comparison ... |
+----+-----+-----+
2 rows in set (0.00 sec)
```

By default, the search is performed in case-insensitive fashion. To perform a case-sensitive full-text search, use a case-sensitive or binary collation for the indexed columns. For example, a column that uses the `utf8mb4` character set of can be assigned a collation of `utf8mb4_0900_as_cs` or `utf8mb4_bin` to make it case-sensitive for full-text searches.

When `MATCH()` is used in a `WHERE` clause, as in the example shown earlier, the rows returned are automatically sorted with the highest relevance first. Relevance values are nonnegative floating-point numbers. Zero relevance means no similarity. Relevance is computed based on the number of words in the row (document), the number of unique words in the row, the total number of words in the collection, and the number of rows that contain a particular word.

Note

The term “document” may be used interchangeably with the term “row”, and both terms refer to the indexed part of the row. The term “collection” refers to the indexed columns and encompasses all rows.

To simply count matches, you could use a query like this:

```
mysql> SELECT COUNT(*) FROM articles
    WHERE MATCH (title,body)
    AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+
| COUNT(*) |
+-----+
```

```

+-----+
|      2 |
+-----+
1 row in set (0.00 sec)

```

You might find it quicker to rewrite the query as follows:

```

mysql> SELECT
      COUNT(IF(MATCH (title,body) AGAINST ('database' IN NATURAL LANGUAGE MODE), 1, NULL))
      AS count
      FROM articles;
+-----+
| count |
+-----+
|      2 |
+-----+
1 row in set (0.03 sec)

```

The first query does some extra work (sorting the results by relevance) but also can use an index lookup based on the `WHERE` clause. The index lookup might make the first query faster if the search matches few rows. The second query performs a full table scan, which might be faster than the index lookup if the search term was present in most rows.

For natural-language full-text searches, the columns named in the `MATCH()` function must be the same columns included in some `FULLTEXT` index in your table. For the preceding query, note that the columns named in the `MATCH()` function (`title` and `body`) are the same as those named in the definition of the `article` table's `FULLTEXT` index. To search the `title` or `body` separately, you would create separate `FULLTEXT` indexes for each column.

You can also perform a boolean search or a search with query expansion. These search types are described in [Section 12.10.2, “Boolean Full-Text Searches”](#), and [Section 12.10.3, “Full-Text Searches with Query Expansion”](#).

A full-text search that uses an index can name columns only from a single table in the `MATCH()` clause because an index cannot span multiple tables. For `MyISAM` tables, a boolean search can be done in the absence of an index (albeit more slowly), in which case it is possible to name columns from multiple tables.

The preceding example is a basic illustration that shows how to use the `MATCH()` function where rows are returned in order of decreasing relevance. The next example shows how to retrieve the relevance values explicitly. Returned rows are not ordered because the `SELECT` statement includes neither `WHERE` nor `ORDER BY` clauses:

```

mysql> SELECT id, MATCH (title,body)
      AGAINST ('Tutorial' IN NATURAL LANGUAGE MODE) AS score
      FROM articles;
+-----+
| id | score |
+-----+
| 1 | 0.22764469683170319 |
| 2 | 0 |
| 3 | 0.22764469683170319 |
| 4 | 0 |
| 5 | 0 |
| 6 | 0 |
+-----+
6 rows in set (0.00 sec)

```

The following example is more complex. The query returns the relevance values and it also sorts the rows in order of decreasing relevance. To achieve this result, specify `MATCH()` twice: once in the `SELECT` list and once in the `WHERE` clause. This causes no additional overhead, because the MySQL optimizer notices that the two `MATCH()` calls are identical and invokes the full-text search code only once.

```

mysql> SELECT id, body, MATCH (title,body) AGAINST
      ('Security implications of running MySQL as root'
      IN NATURAL LANGUAGE MODE) AS score

```

```
FROM articles WHERE MATCH (title,body) AGAINST
('Security implications of running MySQL as root'
IN NATURAL LANGUAGE MODE);
```

id	body	score
4	1. Never run mysqld as root. 2. ...	1.5219271183014
6	When configured properly, MySQL ...	1.3114095926285

2 rows in set (0.00 sec)

A phrase that is enclosed within double quote (") characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, "test phrase" matches "test, phrase". If the phrase contains no words that are in the index, the result is empty. For example, if all words are either stopwords or shorter than the minimum length of indexed words, the result is empty.

The MySQL `FULLTEXT` implementation regards any sequence of true word characters (letters, digits, and underscores) as a word. That sequence may also contain apostrophes ('), but not more than one in a row. This means that `aaa'bbb` is regarded as one word, but `aaa 'bbb` is regarded as two words. Apostrophes at the beginning or the end of a word are stripped by the `FULLTEXT` parser; `'aaa'bbb'` would be parsed as `aaa'bbb`.

The built-in `FULLTEXT` parser determines where words start and end by looking for certain delimiter characters; for example, (space), (comma), and (period). If words are not separated by delimiters (as in, for example, Chinese), the built-in `FULLTEXT` parser cannot determine where a word begins or ends. To be able to add words or other indexed terms in such languages to a `FULLTEXT` index that uses the built-in `FULLTEXT` parser, you must preprocess them so that they are separated by some arbitrary delimiter. Alternatively, you can create `FULLTEXT` indexes using the ngram parser plugin (for Chinese, Japanese, or Korean) or the MeCab parser plugin (for Japanese).

It is possible to write a plugin that replaces the built-in full-text parser. For details, see [The MySQL Plugin API](#). For example parser plugin source code, see the `plugin/fulltext` directory of a MySQL source distribution.

Some words are ignored in full-text searches:

- Any word that is too short is ignored. The default minimum length of words that are found by full-text searches is three characters for `InnoDB` search indexes, or four characters for `MyISAM`. You can control the cutoff by setting a configuration option before creating the index: `innodb_ft_min_token_size` configuration option for `InnoDB` search indexes, or `ft_min_word_len` for `MyISAM`.

Note

This behavior does not apply to `FULLTEXT` indexes that use the ngram parser. For the ngram parser, token length is defined by the `ngram_token_size` option.

- Words in the stopwords list are ignored. A stopwords is a word such as "the" or "some" that is so common that it is considered to have zero semantic value. There is a built-in stopwords list, but it can be overridden by a user-defined list. The stopwords lists and related configuration options are different for `InnoDB` search indexes and `MyISAM` ones. Stopword processing is controlled by the configuration options `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for `InnoDB` search indexes, and `ft_stopword_file` for `MyISAM` ones.

See [Section 12.10.4, "Full-Text Stopwords"](#) to view default stopwords lists and how to change them. The default minimum word length can be changed as described in [Section 12.10.6, "Fine-Tuning MySQL Full-Text Search"](#).

Every correct word in the collection and in the query is weighted according to its significance in the collection or query. Thus, a word that is present in many documents has a lower weight, because it has lower semantic value in this particular collection. Conversely, if the word is rare, it receives a higher weight. The weights of the words are combined to compute the relevance of the row. This technique works best with large collections.

MyISAM Limitation

For very small tables, word distribution does not adequately reflect their semantic value, and this model may sometimes produce bizarre results for search indexes on [MyISAM](#) tables. For example, although the word “MySQL” is present in every row of the [articles](#) table shown earlier, a search for the word in a [MyISAM](#) search index produces no results:

```
mysql> SELECT * FROM articles
      WHERE MATCH (title,body)
      AGAINST ('MySQL' IN NATURAL LANGUAGE MODE);
Empty set (0.00 sec)
```

The search result is empty because the word “MySQL” is present in at least 50% of the rows, and so is effectively treated as a stopwords. This filtering technique is more suitable for large data sets, where you might not want the result set to return every second row from a 1GB table, than for small data sets where it might cause poor results for popular terms.

The 50% threshold can surprise you when you first try full-text searching to see how it works, and makes [InnoDB](#) tables more suited to experimentation with full-text searches. If you create a [MyISAM](#) table and insert only one or two rows of text into it, every word in the text occurs in at least 50% of the rows. As a result, no search returns any results until the table contains more rows. Users who need to bypass the 50% limitation can build search indexes on [InnoDB](#) tables, or use the boolean search mode explained in [Section 12.10.2, “Boolean Full-Text Searches”](#).

12.10.2 Boolean Full-Text Searches

MySQL can perform boolean full-text searches using the [IN BOOLEAN MODE](#) modifier. With this modifier, certain characters have special meaning at the beginning or end of words in the search string. In the following query, the + and - operators indicate that a word must be present or absent, respectively, for a match to occur. Thus, the query retrieves all the rows that contain the word “MySQL” but that do *not* contain the word “YourSQL”:

```
mysql> SELECT * FROM articles WHERE MATCH (title,body)
      AGAINST ('+MySQL -YourSQL' IN BOOLEAN MODE);
```

id	title	body
1	MySQL Tutorial	DBMS stands for DataBase ...
2	How To Use MySQL Well	After you went through a ...
3	Optimizing MySQL	In this tutorial we will show ...
4	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...
6	MySQL Security	When configured properly, MySQL ...

Note

In implementing this feature, MySQL uses what is sometimes referred to as *implied Boolean logic*, in which

- + stands for [AND](#)
- - stands for [NOT](#)

- [no operator] implies OR

Boolean full-text searches have these characteristics:

- They do not automatically sort rows in order of decreasing relevance.
- `InnoDB` tables require a `FULLTEXT` index on all columns of the `MATCH()` expression to perform boolean queries. Boolean queries against a `MyISAM` search index can work even without a `FULLTEXT` index, although a search executed in this fashion would be quite slow.
- The minimum and maximum word length full-text parameters apply to `FULLTEXT` indexes created using the built-in `FULLTEXT` parser and MeCab parser plugin. `innodb_ft_min_token_size` and `innodb_ft_max_token_size` are used for `InnoDB` search indexes. `ft_min_word_len` and `ft_max_word_len` are used for `MyISAM` search indexes.

Minimum and maximum word length full-text parameters do not apply to `FULLTEXT` indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

- The stopword list applies, controlled by `innodb_ft_enable_stopword`, `innodb_ft_server_stopword_table`, and `innodb_ft_user_stopword_table` for `InnoDB` search indexes, and `ft_stopword_file` for `MyISAM` ones.
- `InnoDB` full-text search does not support the use of multiple operators on a single search word, as in this example: `'++apple'`. Use of multiple operators on a single search word returns a syntax error to standard out. `MyISAM` full-text search will successfully process the same search ignoring all operators except for the operator immediately adjacent to the search word.
- `InnoDB` full-text search only supports leading plus or minus signs. For example, `InnoDB` supports `'+apple'` but does not support `'apple+'`. Specifying a trailing plus or minus sign causes `InnoDB` to report a syntax error.
- `InnoDB` full-text search does not support the use of a leading plus sign with wildcard (`'+*'`), a plus and minus sign combination (`'+-'`), or leading a plus and minus sign combination (`'+-apple'`). These invalid queries return a syntax error.
- `InnoDB` full-text search does not support the use of the `@` symbol in boolean full-text searches. The `@` symbol is reserved for use by the `@distance` proximity search operator.
- They do not use the 50% threshold that applies to `MyISAM` search indexes.

The boolean full-text search capability supports the following operators:

- +

A leading or trailing plus sign indicates that this word *must* be present in each row that is returned. `InnoDB` only supports leading plus signs.

- -

A leading or trailing minus sign indicates that this word must *not* be present in any of the rows that are returned. `InnoDB` only supports leading minus signs.

Note: The `-` operator acts only to exclude rows that are otherwise matched by other search terms. Thus, a boolean-mode search that contains only terms preceded by `-` returns an empty result. It does not return “all rows except those containing any of the excluded terms.”

- (no operator)

By default (when neither `+` nor `-` is specified), the word is optional, but the rows that contain it are rated higher. This mimics the behavior of `MATCH() ... AGAINST()` without the `IN BOOLEAN MODE` modifier.

- `@distance`

This operator works on `InnoDB` tables only. It tests whether two or more words all start within a specified distance from each other, measured in words. Specify the search words within a double-quoted string immediately before the `@distance` operator, for example, `MATCH(coll) AGAINST('"word1 word2 word3" @8' IN BOOLEAN MODE)`

- `>` `<`

These two operators are used to change a word's contribution to the relevance value that is assigned to a row. The `>` operator increases the contribution and the `<` operator decreases it. See the example following this list.

- `()`

Parentheses group words into subexpressions. Parenthesized groups can be nested.

- `~`

A leading tilde acts as a negation operator, causing the word's contribution to the row's relevance to be negative. This is useful for marking “noise” words. A row containing such a word is rated lower than others, but is not excluded altogether, as it would be with the `-` operator.

- `*`

The asterisk serves as the truncation (or wildcard) operator. Unlike the other operators, it is *appended* to the word to be affected. Words match if they begin with the word preceding the `*` operator.

If a word is specified with the truncation operator, it is not stripped from a boolean query, even if it is too short or a stopword. Whether a word is too short is determined from the `innodb_ft_min_token_size` setting for `InnoDB` tables, or `ft_min_word_len` for `MyISAM` tables. These options are not applicable to `FULLTEXT` indexes that use the ngram parser.

The wildcarded word is considered as a prefix that must be present at the start of one or more words. If the minimum word length is 4, a search for `' +word +the* '` could return fewer rows than a search for `' +word +the '`, because the second query ignores the too-short search term `the`.

- `"`

A phrase that is enclosed within double quote (`"`) characters matches only rows that contain the phrase *literally, as it was typed*. The full-text engine splits the phrase into words and performs a search in the `FULLTEXT` index for the words. Nonword characters need not be matched exactly: Phrase searching requires only that matches contain exactly the same words as the phrase and in the same order. For example, `"test phrase"` matches `"test, phrase"`.

If the phrase contains no words that are in the index, the result is empty. The words might not be in the index because of a combination of factors: if they do not exist in the text, are stopwords, or are shorter than the minimum length of indexed words.

The following examples demonstrate some search strings that use boolean full-text operators:

- `'apple banana'`

Find rows that contain at least one of the two words.

- `' +apple +juice '`

Find rows that contain both words.

- `' +apple macintosh '`

Find rows that contain the word “apple”, but rank rows higher if they also contain “macintosh”.

- `'+apple -macintosh'`

Find rows that contain the word “apple” but not “macintosh”.

- `'+apple ~macintosh'`

Find rows that contain the word “apple”, but if the row also contains the word “macintosh”, rate it lower than if row does not. This is “softer” than a search for `'+apple -macintosh'`, for which the presence of “macintosh” causes the row not to be returned at all.

- `'+apple +(>turnover <strudel)'`

Find rows that contain the words “apple” and “turnover”, or “apple” and “strudel” (in any order), but rank “apple turnover” higher than “apple strudel”.

- `'apple*'`

Find rows that contain words such as “apple”, “apples”, “applesauce”, or “applet”.

- `'"some words"'`

Find rows that contain the exact phrase “some words” (for example, rows that contain “some words of wisdom” but not “some noise words”). Note that the `"` characters that enclose the phrase are operator characters that delimit the phrase. They are not the quotation marks that enclose the search string itself.

Relevancy Rankings for InnoDB Boolean Mode Search

[InnoDB](#) full-text search is modeled on the [Sphinx](#) full-text search engine, and the algorithms used are based on [BM25](#) and [TF-IDF](#) ranking algorithms. For these reasons, relevancy rankings for [InnoDB](#) boolean full-text search may differ from [MyISAM](#) relevancy rankings.

[InnoDB](#) uses a variation of the “term frequency-inverse document frequency” ([TF-IDF](#)) weighting system to rank a document's relevance for a given full-text search query. The [TF-IDF](#) weighting is based on how frequently a word appears in a document, offset by how frequently the word appears in all documents in the collection. In other words, the more frequently a word appears in a document, and the less frequently the word appears in the document collection, the higher the document is ranked.

How Relevancy Ranking is Calculated

The term frequency ([TF](#)) value is the number of times that a word appears in a document. The inverse document frequency ([IDF](#)) value of a word is calculated using the following formula, where `total_records` is the number of records in the collection, and `matching_records` is the number of records that the search term appears in.

```
${IDF} = log10( ${total_records} / ${matching_records} )
```

When a document contains a word multiple times, the IDF value is multiplied by the TF value:

```
${TF} * ${IDF}
```

Using the [TF](#) and [IDF](#) values, the relevancy ranking for a document is calculated using this formula:

```
${rank} = ${TF} * ${IDF} * ${IDF}
```

The formula is demonstrated in the following examples.

Relevancy Ranking for a Single Word Search

This example demonstrates the relevancy ranking calculation for a single-word search.

```
mysql> CREATE TABLE articles (
```

```
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
title VARCHAR(200),
body TEXT,
FULLTEXT (title,body)
) ENGINE=InnoDB;
Query OK, 0 rows affected (1.04 sec)

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','This database tutorial ...'),
('How To Use MySQL','After you went through a ...'),
('Optimizing Your Database','In this database tutorial ...'),
('MySQL vs. YourSQL','When comparing databases ...'),
('MySQL Security','When configured properly, MySQL ...'),
('Database, Database, Database','database database database'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL Full-Text Indexes', 'MySQL fulltext indexes use a ..');
Query OK, 8 rows affected (0.06 sec)
Records: 8 Duplicates: 0 Warnings: 0

mysql> SELECT id, title, body, MATCH (title,body) AGAINST ('database' IN BOOLEAN MODE)
AS score FROM articles ORDER BY score DESC;
```

id	title	body	score
6	Database, Database, Database	database database database	1.0886961221694946
3	Optimizing Your Database	In this database tutorial ...	0.36289870738983154
1	MySQL Tutorial	This database tutorial ...	0.18144935369491577
2	How To Use MySQL	After you went through a ...	0
4	MySQL vs. YourSQL	When comparing databases ...	0
5	MySQL Security	When configured properly, MySQL ...	0
7	1001 MySQL Tricks	1. Never run mysqld as root. 2. ...	0
8	MySQL Full-Text Indexes	MySQL fulltext indexes use a ..	0

```
8 rows in set (0.00 sec)
```

There are 8 records in total, with 3 that match the “database” search term. The first record ([id 6](#)) contains the search term 6 times and has a relevancy ranking of [1.0886961221694946](#). This ranking value is calculated using a [TF](#) value of 6 (the “database” search term appears 6 times in record [id 6](#)) and an [IDF](#) value of 0.42596873216370745, which is calculated as follows (where 8 is the total number of records and 3 is the number of records that the search term appears in):

```
{IDF} = log10( 8 / 3 ) = 0.42596873216370745
```

The [TF](#) and [IDF](#) values are then entered into the ranking formula:

```
{rank} = {TF} * {IDF} * {IDF}
```

Performing the calculation in the MySQL command-line client returns a ranking value of 1.088696164686938.

```
mysql> SELECT 6*log10(8/3)*log10(8/3);
+-----+
| 6*log10(8/3)*log10(8/3) |
+-----+
| 1.088696164686938 |
+-----+
1 row in set (0.00 sec)
```

Note

You may notice a slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client ([1.0886961221694946](#) versus [1.088696164686938](#)). The difference is due to how the casts between integers and floats/doubles are performed internally by [InnoDB](#) (along with related precision and rounding decisions), and how they are performed elsewhere, such as in the MySQL command-line client or other types of calculators.

Relevancy Ranking for a Multiple Word Search

This example demonstrates the relevancy ranking calculation for a multiple-word full-text search based on the `articles` table and data used in the previous example.

If you search on more than one word, the relevancy ranking value is a sum of the relevancy ranking value for each word, as shown in this formula:

$$\${rank} = \${TF} * \${IDF} * \${IDF} + \${TF} * \${IDF} * \${IDF}$$

Performing a search on two terms ('mysql tutorial') returns the following results:

```
mysql> SELECT id, title, body, MATCH (title,body) AGAINST ('mysql tutorial' IN BOOLEAN MODE)
      AS score FROM articles ORDER BY score DESC;
```

8 rows in set (0.00 sec)

In the first record (`id 8`), 'mysql' appears once and 'tutorial' appears twice. There are six matching records for 'mysql' and two matching records for 'tutorial'. The MySQL command-line client returns the expected ranking value when inserting these values into the ranking formula for a multiple word search:

```
mysql> SELECT (1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2));
```

(1*log10(8/6)*log10(8/6)) + (2*log10(8/2)*log10(8/2))
0.7405621541938003

1 row in set (0.00 sec)

Note

The slight difference in the ranking values returned by the `SELECT ... MATCH ... AGAINST` statement and the MySQL command-line client is explained in the preceding example.

12.10.3 Full-Text Searches with Query Expansion

Full-text search supports query expansion (and in particular, its variant “blind query expansion”). This is generally useful when a search phrase is too short, which often means that the user is relying on implied knowledge that the full-text search engine lacks. For example, a user searching for “database” may really mean that “MySQL”, “Oracle”, “DB2”, and “RDBMS” all are phrases that should match “databases” and should be returned, too. This is implied knowledge.

Blind query expansion (also known as automatic relevance feedback) is enabled by adding `WITH QUERY EXPANSION` or `IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION` following the search phrase. It works by performing the search twice, where the search phrase for the second search is the original search phrase concatenated with the few most highly relevant documents from the first search. Thus, if one of these documents contains the word “databases” and the word “MySQL”, the second search finds the documents that contain the word “MySQL” even if they do not contain the word “database”. The following example shows this difference:

```
mysql> SELECT * FROM articles
      WHERE MATCH (title,body)
```

```

AGAINST ('database' IN NATURAL LANGUAGE MODE);
+-----+-----+
| id | title | body |
+-----+-----+
| 1 | MySQL Tutorial | DBMS stands for DataBase ... |

| 4 | 1001 MySQL Tricks | 1. Never run mysqld as root. 2. ... |
+-----+-----+-----+
6 rows in set (0.00 sec)

```

Another example could be searching for books by Georges Simenon about Maigret, when a user is not sure how to spell “Maigret”. A search for “Megre and the reluctant witnesses” finds only “Maigret and the Reluctant Witnesses” without query expansion. A search with query expansion finds all books with the word “Maigret” on the second pass.

Note

Because blind query expansion tends to increase noise significantly by returning nonrelevant documents, use it only when a search phrase is short.

12.10.4 Full-Text Stopwords

The stopwords list is loaded and searched for full-text queries using the server character set and collation (the values of the `character_set_server` and `collation_server` system variables). False hits or misses might occur for stopwords lookups if the stopwords file or columns used for full-text indexing or searches have a character set or collation different from `character_set_server` or `collation_server`.

Case sensitivity of stopwords lookups depends on the server collation. For example, lookups are case-insensitive if the collation is `utf8mb4_0900_ai_ci`, whereas lookups are case-sensitive if the collation is `utf8mb4_0900_as_cs` or `utf8mb4_bin`.

- [Stopwords for InnoDB Search Indexes](#)
- [Stopwords for MyISAM Search Indexes](#)

Stopwords for InnoDB Search Indexes

InnoDB has a relatively short list of default stopwords, because documents from technical, literary, and other sources often use short words as keywords or in significant phrases. For example, you might search for “to be or not to be” and expect to get a sensible result, rather than having all those words ignored.

To see the default **InnoDB** stopwords list, query the `INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD` table.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
+-----+
| value |
+-----+
| a     |

```

```

```

To define your own stopwords list for all [InnoDB](#) tables, define a table with the same structure as the [INNODB_FT_DEFAULT_STOPWORD](#) table, populate it with stopwords, and set the value of the [innodb_ft_server_stopword_table](#) option to a value in the form *db_name/table_name* before creating the full-text index. The stopwords table must have a single [VARCHAR](#) column named *value*. The following example demonstrates creating and configuring a new global stopwords table for [InnoDB](#).

```

-- Create a new stopwords table

mysql> CREATE TABLE my_stopwords(value VARCHAR(30)) ENGINE = INNODB;
Query OK, 0 rows affected (0.01 sec)

-- Insert stopwords (for simplicity, a single stopwords is used in this example)

mysql> INSERT INTO my_stopwords(value) VALUES ('Ishmael');
Query OK, 1 row affected (0.00 sec)

-- Create the table

mysql> CREATE TABLE opening_lines (
id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
opening_line TEXT(500),
author VARCHAR(200),
title VARCHAR(200)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.01 sec)

-- Insert data into the table

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
('Call me Ishmael.','Herman Melville','Moby-Dick'),
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
('I am an invisible man.','Ralph Ellison','Invisible Man'),
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),

```

```
( 'It was love at first sight.', 'Joseph Heller', 'Catch-22' ),
( 'All this happened, more or less.', 'Kurt Vonnegut', 'Slaughterhouse-Five' ),
( 'Mrs. Dalloway said she would buy the flowers herself.', 'Virginia Woolf', 'Mrs. Dalloway' ),
( 'It was a pleasure to burn.', 'Ray Bradbury', 'Fahrenheit 451' );
Query OK, 8 rows affected (0.00 sec)
Records: 8 Duplicates: 0 Warnings: 0

-- Set the innodb_ft_server_stopword_table option to the new stopwords table

mysql> SET GLOBAL innodb_ft_server_stopword_table = 'test/my_stopwords';
Query OK, 0 rows affected (0.00 sec)

-- Create the full-text index (which rebuilds the table if no FTS_DOC_ID column is defined)

mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (1.17 sec)
Records: 0 Duplicates: 0 Warnings: 1
```

Verify that the specified stopwords ('Ishmael') does not appear by querying the words in `INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE`.

Note

By default, words less than 3 characters in length or greater than 84 characters in length do not appear in an `InnoDB` full-text search index. Maximum and minimum word length values are configurable using the `innodb_ft_max_token_size` and `innodb_ft_min_token_size` variables. This default behavior does not apply to the ngram parser plugin. ngram token size is defined by the `ngram_token_size` option.

```
mysql> SET GLOBAL innodb_ft_aux_table='test/opening_lines';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT word FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 15;
+-----+
| word |
+-----+
| across |
| all |
| burn |
| buy |
| call |
| comes |
| dalloway |
| first |
| flowers |
| happened |
| herself |
| invisible |
| less |
| love |
| man |
+-----+
15 rows in set (0.00 sec)
```

To create stopwords lists on a table-by-table basis, create other stopwords tables and use the `innodb_ft_user_stopword_table` option to specify the stopwords table that you want to use before you create the full-text index.

Stopwords for MyISAM Search Indexes

The stopwords file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, `utf16le`, or `utf32`.

To override the default stopwords list for MyISAM tables, set the `ft_stopword_file` system variable. (See [Section 5.1.8, “Server System Variables”](#).) The variable value should be the path name of the file containing the stopwords list, or the empty string to disable stopwords filtering. The server looks

for the file in the data directory unless an absolute path name is given to specify a different directory. After changing the value of this variable or the contents of the stopwords file, restart the server and rebuild your `FULLTEXT` indexes.

The stopwords list is free-form, separating stopwords with any nonalphanumeric character such as newline, space, or comma. Exceptions are the underscore character (`_`) and a single apostrophe (`'`) which are treated as part of a word. The character set of the stopwords list is the server's default character set; see [Section 10.3.2, "Server Character Set and Collation"](#).

The following list shows the default stopwords for `MyISAM` search indexes. In a MySQL source distribution, you can find this list in the `storage/myisam/ft_static.c` file.

12.10.5 Full-Text Restrictions

- Full-text searches are supported for [InnoDB](#) and [MyISAM](#) tables only.
- Full-text searches are not supported for partitioned tables. See [Section 23.6, “Restrictions and Limitations on Partitioning”](#).
- Full-text searches can be used with most multibyte character sets. The exception is that for Unicode, the [utf8](#) character set can be used, but not the [ucs2](#) character set. Although [FULLTEXT](#) indexes on [ucs2](#) columns cannot be used, you can perform [IN BOOLEAN MODE](#) searches on a [ucs2](#) column that has no such index.

The remarks for [utf8](#) also apply to [utf8mb4](#), and the remarks for [ucs2](#) also apply to [utf16](#), [utf16le](#), and [utf32](#).

- Ideographic languages such as Chinese and Japanese do not have word delimiters. Therefore, the built-in full-text parser *cannot determine where words begin and end in these and other such languages*.

A character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese are provided for use with [InnoDB](#) and [MyISAM](#) tables.

- Although the use of multiple character sets within a single table is supported, all columns in a [FULLTEXT](#) index must use the same character set and collation.
- The [MATCH\(\)](#) column list must match exactly the column list in some [FULLTEXT](#) index definition for the table, unless this [MATCH\(\)](#) is [IN BOOLEAN MODE](#) on a [MyISAM](#) table. For [MyISAM](#) tables, boolean-mode searches can be done on nonindexed columns, although they are likely to be slow.
- The argument to [AGAINST\(\)](#) must be a string value that is constant during query evaluation. This rules out, for example, a table column because that can differ for each row.
- Index hints are more limited for [FULLTEXT](#) searches than for non-[FULLTEXT](#) searches. See [Section 8.9.4, “Index Hints”](#).
- For [InnoDB](#), all DML operations ([INSERT](#), [UPDATE](#), [DELETE](#)) involving columns with full-text indexes are processed at transaction commit time. For example, for an [INSERT](#) operation, an inserted string is tokenized and decomposed into individual words. The individual words are then added to full-text index tables when the transaction is committed. As a result, full-text searches only return committed data.
- The '%' character is not a supported wildcard character for full-text searches.

12.10.6 Fine-Tuning MySQL Full-Text Search

MySQL's full-text search capability has few user-tunable parameters. You can exert more control over full-text searching behavior if you have a MySQL source distribution because some changes require source code modifications. See [Section 2.9, “Installing MySQL from Source”](#).

Full-text search is carefully tuned for effectiveness. Modifying the default behavior in most cases can actually decrease effectiveness. *Do not alter the MySQL sources unless you know what you are doing.*

Most full-text variables described in this section must be set at server startup time. A server restart is required to change them; they cannot be modified while the server is running.

Some variable changes require that you rebuild the [FULLTEXT](#) indexes in your tables. Instructions for doing so are given later in this section.

- [Configuring Minimum and Maximum Word Length](#)
- [Configuring the Natural Language Search Threshold](#)
- [Modifying Boolean Full-Text Search Operators](#)
- [Character Set Modifications](#)
- [Rebuilding InnoDB Full-Text Indexes](#)
- [Optimizing InnoDB Full-Text Indexes](#)
- [Rebuilding MyISAM Full-Text Indexes](#)

Configuring Minimum and Maximum Word Length

The minimum and maximum lengths of words to be indexed are defined by the [innodb_ft_min_token_size](#) and [innodb_ft_max_token_size](#) for [InnoDB](#) search indexes, and [ft_min_word_len](#) and [ft_max_word_len](#) for [MyISAM](#) ones.

**Note**

Minimum and maximum word length full-text parameters do not apply to `FULLTEXT` indexes created using the ngram parser. ngram token size is defined by the `ngram_token_size` option.

After changing any of these options, rebuild your `FULLTEXT` indexes for the change to take effect. For example, to make two-character words searchable, you could put the following lines in an option file:

```
[mysqld]
innodb_ft_min_token_size=2
ft_min_word_len=2
```

Then restart the server and rebuild your `FULLTEXT` indexes. For `MyISAM` tables, note the remarks regarding `myisamchk` in the instructions that follow for rebuilding `MyISAM` full-text indexes.

Configuring the Natural Language Search Threshold

For `MyISAM` search indexes, the 50% threshold for natural language searches is determined by the particular weighting scheme chosen. To disable it, look for the following line in `storage/myisam/ftdefs.h`:

```
#define GWS_IN_USE GWS_PROB
```

Change that line to this:

```
#define GWS_IN_USE GWS_FREQ
```

Then recompile MySQL. There is no need to rebuild the indexes in this case.

**Note**

By making this change, you *severely* decrease MySQL's ability to provide adequate relevance values for the `MATCH()` function. If you really need to search for such common words, it would be better to search using `IN BOOLEAN MODE` instead, which does not observe the 50% threshold.

Modifying Boolean Full-Text Search Operators

To change the operators used for boolean full-text searches on `MyISAM` tables, set the `ft_boolean_syntax` system variable. (`InnoDB` does not have an equivalent setting.) This variable can be changed while the server is running, but you must have privileges sufficient to set global system variables (see [Section 5.1.9.1, “System Variable Privileges”](#)). No rebuilding of indexes is necessary in this case.

Character Set Modifications

For the built-in full-text parser, you can change the set of characters that are considered word characters in several ways, as described in the following list. After making the modification, rebuild the indexes for each table that contains any `FULLTEXT` indexes. Suppose that you want to treat the hyphen character ('-') as a word character. Use one of these methods:

- Modify the MySQL source: In `storage/innobase/handler/ha_innodb.cc` (for `InnoDB`), or in `storage/myisam/ftdefs.h` (for `MyISAM`), see the `true_word_char()` and `misc_word_char()` macros. Add '-' to one of those macros and recompile MySQL.
- Modify a character set file: This requires no recompilation. The `true_word_char()` macro uses a “character type” table to distinguish letters and numbers from other characters. You can edit the contents of the `<ctype><map>` array in one of the character set XML files to specify that '-' is a “letter.” Then use the given character set for your `FULLTEXT` indexes. For information about the `<ctype><map>` array format, see [Section 10.13.1, “Character Definition Arrays”](#).

- Add a new collation for the character set used by the indexed columns, and alter the columns to use that collation. For general information about adding collations, see [Section 10.14, “Adding a Collation to a Character Set”](#). For an example specific to full-text indexing, see [Section 12.10.7, “Adding a User-Defined Collation for Full-Text Indexing”](#).

Rebuilding InnoDB Full-Text Indexes

For the changes to take effect, `FULLTEXT` indexes must be rebuilt after modifying any of the following full-text index variables: `innodb_ft_min_token_size`; `innodb_ft_max_token_size`; `innodb_ft_server_stopword_table`; `innodb_ft_user_stopword_table`; `innodb_ft_enable_stopword`; `ngram_token_size`. Modifying `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, or `ngram_token_size` requires restarting the server.

To rebuild `FULLTEXT` indexes for an `InnoDB` table, use `ALTER TABLE` with the `DROP INDEX` and `ADD INDEX` options to drop and re-create each index.

Optimizing InnoDB Full-Text Indexes

Running `OPTIMIZE TABLE` on a table with a full-text index rebuilds the full-text index, removing deleted Document IDs and consolidating multiple entries for the same word, where possible.

To optimize a full-text index, enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE`.

```
mysql> set GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.01 sec)

mysql> OPTIMIZE TABLE opening_lines;
+-----+-----+-----+-----+
| Table           | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.opening_lines | optimize | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

To avoid lengthy rebuild times for full-text indexes on large tables, you can use the `innodb_ft_num_word_optimize` option to perform the optimization in stages. The `innodb_ft_num_word_optimize` option defines the number of words that are optimized each time `OPTIMIZE TABLE` is run. The default setting is 2000, which means that 2000 words are optimized each time `OPTIMIZE TABLE` is run. Subsequent `OPTIMIZE TABLE` operations continue from where the preceding `OPTIMIZE TABLE` operation ended.

Rebuilding MyISAM Full-Text Indexes

If you modify full-text variables that affect indexing (`ft_min_word_len`, `ft_max_word_len`, or `ft_stopword_file`), or if you change the stopwords file itself, you must rebuild your `FULLTEXT` indexes after making the changes and restarting the server.

To rebuild the `FULLTEXT` indexes for a `MyISAM` table, it is sufficient to do a `QUICK` repair operation:

```
mysql> REPAIR TABLE tbl_name QUICK;
```

Alternatively, use `ALTER TABLE` as just described. In some cases, this may be faster than a repair operation.

Each table that contains any `FULLTEXT` index must be repaired as just shown. Otherwise, queries for the table may yield incorrect results, and modifications to the table will cause the server to see the table as corrupt and in need of repair.

If you use `myisamchk` to perform an operation that modifies `MyISAM` table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the *default* full-text parameter values for minimum word length, maximum word length, and stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or stopwords file values used by the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values for `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` for `MyISAM` table index modification is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE` statements. These statements are performed by the server, which knows the proper full-text parameter values to use.

12.10.7 Adding a User-Defined Collation for Full-Text Indexing

This section describes how to add a user-defined collation for full-text searches using the built-in full-text parser. The sample collation is like `latin1_swedish_ci` but treats the '-' character as a letter rather than as a punctuation character so that it can be indexed as a word character. General information about adding collations is given in [Section 10.14, "Adding a Collation to a Character Set"](#); it is assumed that you have read it and are familiar with the files involved.

To add a collation for full-text indexing, use the following procedure. The instructions here add a collation for a simple character set, which as discussed in [Section 10.14, "Adding a Collation to a Character Set"](#), can be created using a configuration file that describes the character set properties. For a complex character set such as Unicode, create collations using C source files that describe the character set properties.

1. Add a collation to the `Index.xml` file. The permitted range of IDs for user-defined collations is given in [Section 10.14.2, "Choosing a Collation ID"](#). The ID must be unused, so choose a value different from 1025 if that ID is already taken on your system.

```
<charset name="latin1">
...
<collation name="latin1_fulltext_ci" id="1025"/>
</charset>
```

2. Declare the sort order for the collation in the `latin1.xml` file. In this case, the order can be copied from `latin1_swedish_ci`:

```
<collation name="latin1_fulltext_ci">
<map>
00 01 02 03 04 05 06 07 08 09 0A 0B 0C 0D 0E 0F

</map>
```

```
</collation>
```

3. Modify the `ctype` array in `latin1.xml`. Change the value corresponding to 0x2D (which is the code for the '-' character) from 10 (punctuation) to 01 (uppercase letter). In the following array, this is the element in the fourth row down, third value from the end.

```
<ctype>
<map>
00
20 20 20 20 20 20 20 20 20 28 28 28 28 28 20 20
20 20 20 20 20 20 20 20 20 20 20 20 20 20 20 20
48 10 10 10 10 10 10 10 10 10 10 10 10 01 10 10

10 81 81 81 81 81 81 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 01 01 01 01 01 10 10 10 10
10 82 82 82 82 82 82 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 02 02 02 02 02 10 10 10 20
10 00 10 02 10 10 10 10 10 10 01 10 01 00 01 00
00 10 10 10 10 10 10 10 10 10 02 10 02 00 02 01
48 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
10 10 10 10 10 10 10 10 10 10 10 10 10 10 10 10
01 01 01 01 01 01 01 01 01 01 01 01 01 01 01 01
01 01 01 01 01 01 01 10 01 01 01 01 01 01 01 02
02 02 02 02 02 02 02 02 02 02 02 02 02 02 02 02
02 02 02 02 02 02 02 10 02 02 02 02 02 02 02 02
</map>
</ctype>
```

4. Restart the server.
5. To employ the new collation, include it in the definition of columns that are to use it:

```
mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.13 sec)

mysql> CREATE TABLE t1 (
  a TEXT CHARACTER SET latin1 COLLATE latin1_fulltext_ci,
  FULLTEXT INDEX(a)
) ENGINE=InnoDB;
Query OK, 0 rows affected (0.47 sec)
```

6. Test the collation to verify that hyphen is considered as a word character:

```
mysql> INSERT INTO t1 VALUES ('----'),('....'),('abcd');
Query OK, 3 rows affected (0.22 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1 WHERE MATCH a AGAINST ('----' IN BOOLEAN MODE);
+-----+
| a      |
+-----+
| ----  |
+-----+
1 row in set (0.00 sec)
```

12.10.8 ngram Full-Text Parser

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation, MySQL provides an ngram full-text parser that supports Chinese, Japanese, and Korean (CJK). The ngram full-text parser is supported for use with [InnoDB](#) and [MyISAM](#).

Note

MySQL also provides a MeCab full-text parser plugin for Japanese, which tokenizes documents into meaningful words. For more information, see [Section 12.10.9, “MeCab Full-Text Parser Plugin”](#).

An ngram is a contiguous sequence of *n* characters from a given sequence of text. The ngram parser tokenizes a sequence of text into a contiguous sequence of *n* characters. For example, you can tokenize “abcd” for different values of *n* using the ngram full-text parser.

```
n=1: 'a', 'b', 'c', 'd'
n=2: 'ab', 'bc', 'cd'
n=3: 'abc', 'bcd'
n=4: 'abcd'
```

The ngram full-text parser is a built-in server plugin. As with other built-in server plugins, it is automatically loaded when the server is started.

The full-text search syntax described in [Section 12.10, “Full-Text Search Functions”](#) applies to the ngram parser plugin. Differences in parsing behavior are described in this section. Full-text-related configuration options, except for minimum and maximum word length options (`innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, `ft_max_word_len`) are also applicable.

Configuring ngram Token Size

The ngram parser has a default ngram token size of 2 (bigram). For example, with a token size of 2, the ngram parser parses the string “abc def” into four tokens: “ab”, “bc”, “de” and “ef”.

ngram token size is configurable using the `ngram_token_size` configuration option, which has a minimum value of 1 and maximum value of 10.

Typically, `ngram_token_size` is set to the size of the largest token that you want to search for. If you only intend to search for single characters, set `ngram_token_size` to 1. A smaller token size produces a smaller full-text search index, and faster searches. If you need to search for words comprised of more than one character, set `ngram_token_size` accordingly. For example, “Happy Birthday” is “生日快乐” in simplified Chinese, where “生日” is “birthday”, and “快乐” translates as “happy”. To search on two-character words such as these, set `ngram_token_size` to a value of 2 or higher.

As a read-only variable, `ngram_token_size` may only be set as part of a startup string or in a configuration file:

- Startup string:

```
mysqld --ngram_token_size=2
```

- Configuration file:

```
[mysqld]
ngram_token_size=2
```

Note

The following minimum and maximum word length configuration options are ignored for `FULLTEXT` indexes that use the ngram parser: `innodb_ft_min_token_size`, `innodb_ft_max_token_size`, `ft_min_word_len`, and `ft_max_word_len`.

Creating a FULLTEXT Index that Uses the ngram Parser

To create a `FULLTEXT` index that uses the ngram parser, specify `WITH PARSE` `ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

The following example demonstrates creating a table with an `ngram FULLTEXT` index, inserting sample data (Simplified Chinese text), and viewing tokenized data in the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table.

```
mysql> USE test;
```

```
mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body) WITH PARSE ngram
) ENGINE=InnoDB CHARACTER SET utf8mb4;

mysql> SET NAMES utf8mb4;

INSERT INTO articles (title,body) VALUES
    ('数据库管理','在本教程中我将向你展示如何管理数据库'),
    ('数据库应用开发','学习开发数据库应用程序');

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a [FULLTEXT](#) index to an existing table, you can use [ALTER TABLE](#) or [CREATE INDEX](#). For example:

```
CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSE ngram;

# Or:

CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSE ngram;
```

ngram Parser Space Handling

The ngram parser eliminates spaces when parsing. For example:

- “ab cd” is parsed to “ab”, “cd”
- “a bc” is parsed to “bc”

ngram Parser Stopword Handling

The built-in MySQL full-text parser compares words to entries in the stopwords list. If a word is equal to an entry in the stopwords list, the word is excluded from the index. For the ngram parser, stopwords handling is performed differently. Instead of excluding tokens that are equal to entries in the stopwords list, the ngram parser excludes tokens that *contain* stopwords. For example, assuming [ngram_token_size=2](#), a document that contains “a,b” is parsed to “a,” and “,b”. If a comma (“,”) is defined as a stopword, both “a,” and “,b” are excluded from the index because they contain a comma.

By default, the ngram parser uses the default stopwords list, which contains a list of English stopwords. For a stopwords list applicable to Chinese, Japanese, or Korean, you must create your own. For information about creating a stopwords list, see [Section 12.10.4, “Full-Text Stopwords”](#).

Stopwords greater in length than [ngram_token_size](#) are ignored.

ngram Parser Term Search

For *natural language mode* search, the search term is converted to a union of ngram terms. For example, the string “abc” (assuming [ngram_token_size=2](#)) is converted to “ab bc”. Given two documents, one containing “ab” and the other containing “abc”, the search term “ab bc” matches both documents.

For *boolean mode* search, the search term is converted to an ngram phrase search. For example, the string ‘abc’ (assuming [ngram_token_size=2](#)) is converted to “ab bc”. Given two documents, one

containing 'ab' and the other containing 'abc', the search phrase "ab bc" only matches the document containing 'abc'.

ngram Parser Wildcard Search

Because an ngram [FULLTEXT](#) index contains only ngrams, and does not contain information about the beginning of terms, wildcard searches may return unexpected results. The following behaviors apply to wildcard searches using ngram [FULLTEXT](#) search indexes:

- If the prefix term of a wildcard search is shorter than ngram token size, the query returns all indexed rows that contain ngram tokens starting with the prefix term. For example, assuming `ngram_token_size=2`, a search on "a*" returns all rows starting with "a".
- If the prefix term of a wildcard search is longer than ngram token size, the prefix term is converted to an ngram phrase and the wildcard operator is ignored. For example, assuming `ngram_token_size=2`, an "abc*" wildcard search is converted to "ab bc".

ngram Parser Phrase Search

Phrase searches are converted to ngram phrase searches. For example, The search phrase "abc" is converted to "ab bc", which returns documents containing "abc" and "ab bc".

The search phrase "abc def" is converted to "ab bc de ef", which returns documents containing "abc def" and "ab bc de ef". A document that contains "abcdef" is not returned.

12.10.9 MeCab Full-Text Parser Plugin

The built-in MySQL full-text parser uses the white space between words as a delimiter to determine where words begin and end, which is a limitation when working with ideographic languages that do not use word delimiters. To address this limitation for Japanese, MySQL provides a MeCab full-text parser plugin. The MeCab full-text parser plugin is supported for use with [InnoDB](#) and [MyISAM](#).

Note

MySQL also provides an ngram full-text parser plugin that supports Japanese. For more information, see [Section 12.10.8, "ngram Full-Text Parser"](#).

The MeCab full-text parser plugin is a full-text parser plugin for Japanese that tokenizes a sequence of text into meaningful words. For example, MeCab tokenizes "データベース管理" ("Database Management") into "データベース" ("Database") and "管理" ("Management"). By comparison, the [ngram](#) full-text parser tokenizes text into a contiguous sequence of `n` characters, where `n` represents a number between 1 and 10.

In addition to tokenizing text into meaningful words, MeCab indexes are typically smaller than ngram indexes, and MeCab full-text searches are generally faster. One drawback is that it may take longer for the MeCab full-text parser to tokenize documents, compared to the ngram full-text parser.

The full-text search syntax described in [Section 12.10, "Full-Text Search Functions"](#) applies to the MeCab parser plugin. Differences in parsing behavior are described in this section. Full-text related configuration options are also applicable.

For additional information about the MeCab parser, refer to the [MeCab: Yet Another Part-of-Speech and Morphological Analyzer](#) project on Github.

Installing the MeCab Parser Plugin

The MeCab parser plugin requires `mecab` and `mecab-ipadic`.

On supported Fedora, Debian and Ubuntu platforms (except Ubuntu 12.04 where the system `mecab` version is too old), MySQL dynamically links to the system `mecab` installation if it is installed to

the default location. On other supported Unix-like platforms, `libmecab.so` is statically linked in `libpluginmecab.so`, which is located in the MySQL plugin directory. `mecab-ipadic` is included in MySQL binaries and is located in `MYSQL_HOME/lib/mecab`.

You can install `mecab` and `mecab-ipadic` using a native package management utility (on Fedora, Debian, and Ubuntu), or you can build `mecab` and `mecab-ipadic` from source. For information about installing `mecab` and `mecab-ipadic` using a native package management utility, see [Installing MeCab From a Binary Distribution \(Optional\)](#). If you want to build `mecab` and `mecab-ipadic` from source, see [Building MeCab From Source \(Optional\)](#).

On Windows, `libmecab.dll` is found in the MySQL `bin` directory. `mecab-ipadic` is located in `MYSQL_HOME/lib/mecab`.

To install and configure the MeCab parser plugin, perform the following steps:

1. In the MySQL configuration file, set the `mecab_rc_file` configuration option to the location of the `mecabrc` configuration file, which is the configuration file for MeCab. If you are using the MeCab package distributed with MySQL, the `mecabrc` file is located in `MYSQL_HOME/lib/mecab/etc/`.

```
[mysqld]
loose-mecab-rc-file=MYSQL_HOME/lib/mecab/etc/mecabrc
```

The `loose` prefix is an [option modifier](#). The `mecab_rc_file` option is not recognized by MySQL until the MeCab parser plugin is installed but it must be set before attempting to install the MeCab parser plugin. The `loose` prefix allows you restart MySQL without encountering an error due to an unrecognized variable.

If you use your own MeCab installation, or build MeCab from source, the location of the `mecabrc` configuration file may differ.

For information about the MySQL configuration file and its location, see [Section 4.2.2.2, “Using Option Files”](#).

2. Also in the MySQL configuration file, set the minimum token size to 1 or 2, which are the values recommended for use with the MeCab parser. For `InnoDB` tables, minimum token size is defined by the `innodb_ft_min_token_size` configuration option, which has a default value of 3. For `MyISAM` tables, minimum token size is defined by `ft_min_word_len`, which has a default value of 4.

```
[mysqld]
innodb_ft_min_token_size=1
```

3. Modify the `mecabrc` configuration file to specify the dictionary you want to use. The `mecab-ipadic` package distributed with MySQL binaries includes three dictionaries (`ipadic_euc-jp`, `ipadic_sjis`, and `ipadic_utf-8`). The `mecabrc` configuration file packaged with MySQL contains an entry similar to the following:

```
dicdir = /path/to/mysql/lib/mecab/lib/mecab/dic/ipadic_euc-jp
```

To use the `ipadic_utf-8` dictionary, for example, modify the entry as follows:

```
dicdir=MYSQL_HOME/lib/mecab/dic/ipadic_utf-8
```

If you are using your own MeCab installation or have built MeCab from source, the default `dicdir` entry in the `mecabrc` file will differ, as will the dictionaries and their location.

Note

After the MeCab parser plugin is installed, you can use the `mecab_charset` status variable to view the character set used with MeCab. The three MeCab dictionaries provided with the MySQL binary support the following character sets.

- The `ipadic_euc-jp` dictionary supports the `ujis` and `eucjpm`s character sets.
- The `ipadic_sjis` dictionary supports the `sjis` and `cp932` character sets.
- The `ipadic_utf-8` dictionary supports the `utf8` and `utf8mb4` character sets.

`mecab_charset` only reports the first supported character set. For example, the `ipadic_utf-8` dictionary supports both `utf8` and `utf8mb4`. `mecab_charset` always reports `utf8` when this dictionary is in use.

4. Restart MySQL.

5. Install the MeCab parser plugin:

The MeCab parser plugin is installed using `INSTALL PLUGIN` syntax. The plugin name is `mecab`, and the shared library name is `libpluginmecab.so`. For additional information about installing plugins, see [Section 5.6.1, “Installing and Uninstalling Plugins”](#).

```
INSTALL PLUGIN mecab SONAME 'libpluginmecab.so';
```

Once installed, the MeCab parser plugin loads at every normal MySQL restart.

6. Verify that the MeCab parser plugin is loaded using the `SHOW PLUGINS` statement.

```
mysql> SHOW PLUGINS;
```

A `mecab` plugin should appear in the list of plugins.

Creating a FULLTEXT Index that uses the MeCab Parser

To create a `FULLTEXT` index that uses the mecab parser, specify `WITH PARSE`r `ngram` with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`.

This example demonstrates creating a table with a `mecab FULLTEXT` index, inserting sample data, and viewing tokenized data in the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table:

```
mysql> USE test;

mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body) WITH PARSEr mecab
) ENGINE=InnoDB CHARACTER SET utf8;

mysql> SET NAMES utf8;

mysql> INSERT INTO articles (title,body) VALUES
  ('データベース管理','このチュートリアルでは、私はどのようにデータベースを管理する方法を紹介します'),
  ('データベースアプリケーション開発','データベースアプリケーションを開発することを学ぶ');

mysql> SET GLOBAL innodb_ft_aux_table="test/articles";

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE ORDER BY doc_id, position;
```

To add a `FULLTEXT` index to an existing table, you can use `ALTER TABLE` or `CREATE INDEX`. For example:

```
CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
```

```
body TEXT
) ENGINE=InnoDB CHARACTER SET utf8;

ALTER TABLE articles ADD FULLTEXT INDEX ft_index (title,body) WITH PARSEr mecab;

# Or:

CREATE FULLTEXT INDEX ft_index ON articles (title,body) WITH PARSEr mecab;
```

MeCab Parser Space Handling

The MeCab parser uses spaces as separators in query strings. For example, the MeCab parser tokenizes データベース管理 as データベース and 管理.

MeCab Parser Stopword Handling

By default, the MeCab parser uses the default stopword list, which contains a short list of English stopwords. For a stopword list applicable to Japanese, you must create your own. For information about creating stopword lists, see [Section 12.10.4, “Full-Text Stopwords”](#).

MeCab Parser Term Search

For natural language mode search, the search term is converted to a union of tokens. For example, データベース管理 is converted to データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN NATURAL LANGUAGE MODE);
```

For boolean mode search, the search term is converted to a search phrase. For example, データベース管理 is converted to データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース管理' IN BOOLEAN MODE);
```

MeCab Parser Wildcard Search

Wildcard search terms are not tokenized. A search on データベース管理* is performed on the prefix, データベース管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('データベース*' IN BOOLEAN MODE);
```

MeCab Parser Phrase Search

Phrases are tokenized. For example, データベース管理 is tokenized as データベース 管理.

```
SELECT COUNT(*) FROM articles WHERE MATCH(title,body) AGAINST('"データベース管理"' IN BOOLEAN MODE);
```

Installing MeCab From a Binary Distribution (Optional)

This section describes how to install [mecab](#) and [mecab-ipadic](#) from a binary distribution using a native package management utility. For example, on Fedora, you can use Yum to perform the installation:

```
yum mecab-devel
```

On Debian or Ubuntu, you can perform an APT installation:

```
apt-get install mecab
apt-get install mecab-ipadic
```

Installing MeCab From Source (Optional)

If you want to build [mecab](#) and [mecab-ipadic](#) from source, basic installation steps are provided below. For additional information, refer to the MeCab documentation.

1. Download the tar.gz packages for `mecab` and `mecab-ipadic` from <http://taku910.github.io/mecab/#download>. As of February, 2016, the latest available packages are `mecab-0.996.tar.gz` and `mecab-ipadic-2.7.0-20070801.tar.gz`.

2. Install `mecab`:

```
tar xzfv mecab-0.996.tar
cd mecab-0.996
./configure
make
make check
su
make install
```

3. Install `mecab-ipadic`:

```
tar xzfv mecab-ipadic-2.7.0-20070801.tar
cd mecab-ipadic-2.7.0-20070801
./configure
make
su
make install
```

4. Compile MySQL using the `WITH_MECAB` CMake option. Set the `WITH_MECAB` option to `system` if you have installed `mecab` and `mecab-ipadic` to the default location.

```
-DWITH_MECAB=system
```

If you defined a custom installation directory, set `WITH_MECAB` to the custom directory. For example:

```
-DWITH_MECAB=/path/to/mecab
```

12.11 Cast Functions and Operators

Table 12.15 Cast Functions and Operators

Name	Description
<code>BINARY</code>	Cast a string to a binary string
<code>CAST()</code>	Cast a value as a certain type
<code>CONVERT()</code>	Cast a value as a certain type

Cast functions and operators enable conversion of values from one data type to another.

`CONVERT()` with a `USING` clause converts data between different character sets:

```
CONVERT(expr USING transcoding_name)
```

In MySQL, transcoding names are the same as the corresponding character set names.

Examples:

```
SELECT CONVERT('test' USING utf8mb4);
SELECT CONVERT(_latin1'Müller' USING utf8mb4);
INSERT INTO utf8mb4_table (utf8mb4_column)
  SELECT CONVERT(latin1_column USING utf8mb4) FROM latin1_table;
```

To convert strings between different character sets, you can also use `CONVERT(expr, type)` syntax (without `USING`), or `CAST(expr AS type)`, which is equivalent:

```
CONVERT(string, CHAR[(N)] CHARACTER SET charset_name)
CAST(string AS CHAR[(N)] CHARACTER SET charset_name)
```

Examples:

```
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4);
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4);
```

If you specify `CHARACTER SET charset_name` as just shown, the character set and collation of the result are *charset_name* and the default collation of *charset_name*. If you omit `CHARACTER SET charset_name`, the character set and collation of the result are defined by the `character_set_connection` and `collation_connection` system variables that determine the default connection character set and collation (see [Section 10.4, “Connection Character Sets and Collations”](#)).

A `COLLATE` clause is not permitted within a `CONVERT()` or `CAST()` call, but you can apply it to the function result. For example, these are legal:

```
SELECT CONVERT('test' USING utf8mb4) COLLATE utf8mb4_bin;
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_bin;
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4) COLLATE utf8mb4_bin;
```

But these are illegal:

```
SELECT CONVERT('test' USING utf8mb4 COLLATE utf8mb4_bin);
SELECT CONVERT('test', CHAR CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
SELECT CAST('test' AS CHAR CHARACTER SET utf8mb4 COLLATE utf8mb4_bin);
```

Normally, you cannot compare a `BLOB` value or other binary string in case-insensitive fashion because binary strings use the `binary` character set, which has no collation with the concept of lettercase. To perform a case-insensitive comparison, first use the `CONVERT()` or `CAST()` function to convert the value to a nonbinary string. Comparisons of the resulting string use its collation. For example, if the conversion result character set has a case-insensitive collation, a `LIKE` operation is not case-sensitive. That is true for the following operation because the default `utf8mb4` collation (`utf8mb4_0900_ai_ci`) is not case-sensitive:

```
SELECT 'A' LIKE CONVERT(blob_col USING utf8mb4)
FROM tbl_name;
```

To specify a particular collation for the converted string, use a `COLLATE` clause following the `CONVERT()` call:

```
SELECT 'A' LIKE CONVERT(blob_col USING utf8mb4) COLLATE utf8mb4_unicode_ci
FROM tbl_name;
```

To use a different character set, substitute its name for `utf8mb4` in the preceding statements (and similarly to use a different collation).

`CONVERT()` and `CAST()` can be used more generally for comparing strings represented in different character sets. For example, a comparison of these strings results in an error because they have different character sets:

```
mysql> SET @s1 = _latin1 'abc', @s2 = _latin2 'abc';
mysql> SELECT @s1 = @s2;
ERROR 1267 (HY000): Illegal mix of collations (latin1_swedish_ci,IMPLICIT)
and (latin2_general_ci,IMPLICIT) for operation '='

```

Converting one of the strings to a character set compatible with the other enables the comparison to occur without error:

```
mysql> SELECT @s1 = CONVERT(@s2 USING latin1);
+-----+
| @s1 = CONVERT(@s2 USING latin1) |
+-----+
| 1 |
+-----+
```

For string literals, another way to specify the character set is to use a character set introducer. `_latin1` and `_latin2` in the preceding example are instances of introducers. Unlike conversion functions such as `CAST()`, or `CONVERT()`, which convert a string from one character set to another, an

introducer designates a string literal as having a particular character set, with no conversion involved. For more information, see [Section 10.3.8, “Character Set Introducers”](#).

Character set conversion is also useful preceding lettercase conversion of binary strings. `LOWER()` and `UPPER()` are ineffective when applied directly to binary strings because the concept of lettercase does not apply. To perform lettercase conversion of a binary string, first convert it to a nonbinary string using a character set appropriate for the data stored in the string:

```
mysql> SET @str = BINARY 'New York';
mysql> SELECT LOWER(@str), LOWER(CONVERT(@str USING utf8mb4));
+-----+-----+
| LOWER(@str) | LOWER(CONVERT(@str USING utf8mb4)) |
+-----+-----+
| New York    | new york                            |
+-----+-----+
```

Be aware that if you convert an indexed column using `BINARY`, `CAST()`, or `CONVERT()`, MySQL may not be able to use the index efficiently.

The cast functions are useful for creating a column with a specific type in a `CREATE TABLE ... SELECT` statement:

```
mysql> CREATE TABLE new_table SELECT CAST('2000-01-01' AS DATE) AS c1;
mysql> SHOW CREATE TABLE new_table\G
***** 1. row *****
      Table: new_table
      Create Table: CREATE TABLE `new_table` (
        `c1` date DEFAULT NULL
      ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
```

The cast functions are useful for sorting `ENUM` columns in lexical order. Normally, sorting of `ENUM` columns occurs using the internal numeric values. Casting the values to `CHAR` results in a lexical sort:

```
SELECT enum_col FROM tbl_name ORDER BY CAST(enum_col AS CHAR);
```

`CAST()` also changes the result if you use it as part of a more complex expression such as `CONCAT('Date: ', CAST(NOW() AS DATE))`.

For temporal values, there is little need to use `CAST()` to extract data in different formats. Instead, use a function such as `EXTRACT()`, `DATE_FORMAT()`, or `TIME_FORMAT()`. See [Section 12.7, “Date and Time Functions”](#).

To cast a string to a number, you normally need do nothing other than use the string value in numeric context:

```
mysql> SELECT 1+'1';
-> 2
```

That is also true for hexadecimal and bit literals, which are binary strings by default:

```
mysql> SELECT X'41', X'41'+0;
-> 'A', 65
mysql> SELECT b'1100001', b'1100001'+0;
-> 'a', 97
```

A string used in an arithmetic operation is converted to a floating-point number during expression evaluation.

A number used in string context is converted to a string:

```
mysql> SELECT CONCAT('hello you ',2);
-> 'hello you 2'
```

For information about implicit conversion of numbers to strings, see [Section 12.3, “Type Conversion in Expression Evaluation”](#).

MySQL supports arithmetic with both signed and unsigned 64-bit values. For numeric operators (such as `+` or `-`) where one of the operands is an unsigned integer, the result is unsigned by default (see [Section 12.6.1, “Arithmetic Operators”](#)). To override this, use the `SIGNED` or `UNSIGNED` cast operator to cast a value to a signed or unsigned 64-bit integer, respectively.

```
mysql> SELECT 1 - 2;
-> -1
mysql> SELECT CAST(1 - 2 AS UNSIGNED);
-> 18446744073709551615
mysql> SELECT CAST(CAST(1 - 2 AS UNSIGNED) AS SIGNED);
-> -1
```

If either operand is a floating-point value, the result is a floating-point value and is not affected by the preceding rule. (In this context, `DECIMAL` column values are regarded as floating-point values.)

```
mysql> SELECT CAST(1 AS UNSIGNED) - 2.0;
-> -1.0
```

The SQL mode affects the result of conversion operations (see [Section 5.1.11, “Server SQL Modes”](#)). Examples:

- For conversion of a “zero” date string to a date, `CONVERT()` and `CAST()` return `NULL` and produce a warning when the `NO_ZERO_DATE` SQL mode is enabled.
- For integer subtraction, if the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the subtraction result is signed even if any operand is unsigned.

The following list describes the available cast functions and operators:

- `BINARY expr`

The `BINARY` operator converts the expression to a binary string (a string that has the `binary` character set and `binary` collation). A common use for `BINARY` is to force a character string comparison to be done byte by byte using numeric byte values rather than character by character. The `BINARY` operator also causes trailing spaces in comparisons to be significant. For information about the differences between the `binary` collation of the `binary` character set and the `_bin` collations of nonbinary character sets, see [Section 10.8.5, “The binary Collation Compared to _bin Collations”](#).

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT BINARY 'a' = 'A';
-> 0
mysql> SELECT 'a' = 'a ';
-> 1
mysql> SELECT BINARY 'a' = 'a ';
-> 0
```

In a comparison, `BINARY` affects the entire operation; it can be given before either operand with the same result.

To convert a string expression to a binary string, these constructs are equivalent:

```
BINARY expr
CAST(expr AS BINARY)
CONVERT(expr USING BINARY)
```

If a value is a string literal, it can be designated as a binary string without performing any conversion by using the `_binary` character set introducer:

```
mysql> SELECT 'a' = 'A';
-> 1
mysql> SELECT _binary 'a' = 'A';
-> 0
```

For information about introducers, see [Section 10.3.8, “Character Set Introducers”](#).

The `BINARY` operator in expressions differs in effect from the `BINARY` attribute in character column definitions. A character column defined with the `BINARY` attribute is assigned the table default character set and the binary (`_bin`) collation of that character set. Every nonbinary character set has a `_bin` collation. For example, if the table default character set is `utf8mb4`, these two column definitions are equivalent:

```
CHAR(10) BINARY
CHAR(10) CHARACTER SET utf8mb4 COLLATE utf8mb4_bin
```

The use of `CHARACTER SET binary` in the definition of a `CHAR`, `VARCHAR`, or `TEXT` column causes the column to be treated as the corresponding binary string data type. For example, the following pairs of definitions are equivalent:

```
CHAR(10) CHARACTER SET binary
BINARY(10)

VARCHAR(10) CHARACTER SET binary
VARBINARY(10)

TEXT CHARACTER SET binary
BLOB
```

- `CAST(expr AS type [ARRAY])`

```
CAST(timestamp_value AT TIME ZONE timezone_specifier AS
DATETIME[(precision)])
```

`timezone_specifier`: `[INTERVAL] '+00:00' | 'UTC'`

The `CAST()` function takes an expression of any type and produces a result value of the specified type, similar to `CONVERT()`. For more information, see the description of `CONVERT()`.

In MySQL 8.0.17 and later, `InnoDB` allows the use of an additional `ARRAY` keyword for creating a multi-valued index on a `JSON` array as part of `CREATE INDEX`, `CREATE TABLE`, and `ALTER TABLE` statements. `ARRAY` is not supported except when used to create a multi-valued index in one of these statements, in which case it is required. The column being indexed must be a column of type `JSON`. With `ARRAY`, the `type` following the `AS` keyword may specify any of the types supported by `CAST()`, with the exceptions of `BINARY`, `JSON`, and `YEAR`. For syntax information and examples, as well as other relevant information, see [Multi-Valued Indexes](#).

Note

Unlike `CAST()`, `CONVERT()` does *not* support multi-valued index creation or the `ARRAY` keyword.

Beginning with MySQL 8.0.22, `CAST()` supports retrieval of a `TIMESTAMP` value as being in UTC, using the `AT TIMEZONE` operator. The only supported time zone is UTC; this can be specified as either of `'+00:00'` or `'UTC'`. The only return type supported by this syntax is `DATETIME`, with an optional precision specifier in the range of 0 to 6, inclusive.

`TIMESTAMP` values that use timezone offsets are also supported.

```
mysql> SELECT @@system_time_zone;
+-----+
| @@system_time_zone |
+-----+
| EDT                |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE TZ (c TIMESTAMP);
Query OK, 0 rows affected (0.41 sec)

mysql> INSERT INTO tz VALUES
```

```

> ROW(CURRENT_TIMESTAMP),
> ROW('2020-07-28 14:50:15+1:00');
Query OK, 1 row affected (0.08 sec)

mysql> TABLE tz;
+-----+
| c      |
+-----+
| 2020-07-28 09:22:41 |
| 2020-07-28 09:50:15 |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT CAST(c AT TIME ZONE '+00:00' AS DATETIME) AS u FROM tz;
+-----+
| u      |
+-----+
| 2020-07-28 13:22:41 |
| 2020-07-28 13:50:15 |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT CAST(c AT TIME ZONE 'UTC' AS DATETIME(2)) AS u FROM tz;
+-----+
| u      |
+-----+
| 2020-07-28 13:22:41.00 |
| 2020-07-28 13:50:15.00 |
+-----+
2 rows in set (0.00 sec)

```

If you use 'UTC' as the time zone specifier with this form of `CAST()`, and the server raises an error such as `Unknown or incorrect time zone: 'UTC'`, you may need to install the MySQL time zone tables (see [Populating the Time Zone Tables](#)).

`AT TIME ZONE` does not support the `ARRAY` keyword, and is not supported by the `CONVERT()` function.

- `CONVERT(expr USING transcoding_name), CONVERT(expr, type)`

The `CONVERT()` function takes an expression of any type and produces a result value of the specified type.

`CONVERT(... USING ...)` is standard SQL syntax. The non-`USING` form of `CONVERT()` is ODBC syntax.

`CONVERT(expr USING transcoding_name)` converts data between different character sets. In MySQL, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the `utf8mb4` character set:

```
SELECT CONVERT('abc' USING utf8mb4);
```

`CONVERT(expr, type)` syntax (without `USING`) takes an expression and a `type` value specifying the result type. This operation may also be expressed as `CAST(expr AS type)`, which is equivalent. These `type` values are permitted:

- `BINARY[(N)]`

Produces a string with the `BINARY` data type. For a description of how this affects comparisons, see [Section 11.3.3, "The BINARY and VARBINARY Types"](#). If the optional length `N` is given,

`BINARY(N)` causes the cast to use no more than *N* bytes of the argument. Values shorter than *N* bytes are padded with `0x00` bytes to a length of *N*.

- `CHAR(N) [charset_info]`

Produces a string with the `CHAR` data type. If the optional length *N* is given, `CHAR(N)` causes the cast to use no more than *N* characters of the argument. No padding occurs for values shorter than *N* characters.

With no *charset_info* clause, `CHAR` produces a string with the default character set. To specify the character set explicitly, these *charset_info* values are permitted:

- `CHARACTER SET charset_name`: Produces a string with the given character set.
- `ASCII`: Shorthand for `CHARACTER SET latin1`.
- `UNICODE`: Shorthand for `CHARACTER SET ucs2`.

In all cases, the string has the character set default collation.

- `DATE`

Produces a `DATE` value.

- `DATETIME`

Produces a `DATETIME` value.

- `DECIMAL(M,D)`

Produces a `DECIMAL` value. If the optional *M* and *D* values are given, they specify the maximum number of digits (the precision) and the number of digits following the decimal point (the scale).

- `DOUBLE`

Produces a `DOUBLE` result. Added in MySQL 8.0.17.

- `FLOAT(p)`

If the precision *p* is not specified, produces a result of type `FLOAT`. If *p* is provided and $0 \leq p \leq 24$, the result is of type `FLOAT`. If $25 \leq p \leq 53$, the result is of type `DOUBLE`. If $p < 0$ or $p > 53$, an error is returned. Added in MySQL 8.0.17.

- `JSON`

Produces a `JSON` value. For details on the rules for conversion of values between `JSON` and other types, see [Comparison and Ordering of JSON Values](#).

- `NCHAR(N)`

Like `CHAR`, but produces a string with the national character set. See [Section 10.3.7, “The National Character Set”](#).

Unlike `CHAR`, `NCHAR` does not permit trailing character set information to be specified.

- `REAL`

Produces a result of type `REAL`. This is actually `FLOAT` if `REAL_AS_FLOAT` SQL mode is enabled; otherwise the result is of type `DOUBLE`.

- `SIGNED [INTEGER]`

Produces a signed integer value.

- `TIME`

Produces a `TIME` value.

- `UNSIGNED [INTEGER]`

Produces an unsigned integer value.

- `YEAR`

Produces a `YEAR` value. Added in MySQL 8.0.22. The rules governing conversion to `YEAR` are listed here:

- For a four-digit number in the range 1901-2155 inclusive, or for a string which can be interpreted as a four-digit number in this range, return the corresponding `YEAR` value.
- For a number consisting of one or two digits, or for a string which can be interpreted as such a number, return a `YEAR` value as follows:
 - If the number is in the range 1-69 inclusive, add 2000 and return the sum.
 - If the number is in the range 70-99 inclusive, add 1900 and return the sum.
- For a string which evaluates to 0, return 2000.
- For the number 0, return 0.
- For a `DATE`, `DATETIME`, or `TIMESTAMP` value, return the `YEAR` portion of the value. For a `TIME` value, return the current year.

If you do not specify the type of a `TIME` argument, you may get a different result from what you expect, as shown here:

```
mysql> SELECT CONVERT("11:35:00", YEAR), CONVERT(TIME "11:35:00", YEAR);
+-----+-----+
| CONVERT("11:35:00", YEAR) | CONVERT(TIME "11:35:00", YEAR) |
+-----+-----+
| 2011 | 2020 |
+-----+-----+
```

- If the argument is of type `DECIMAL`, `DOUBLE`, `DECIMAL`, or `REAL`, round the value to the nearest integer, then attempt to cast the value to `YEAR` using the rules for integer values, as shown here:

```
mysql> SELECT CONVERT(1944.35, YEAR), CONVERT(1944.50, YEAR);
+-----+-----+
| CONVERT(1944.35, YEAR) | CONVERT(1944.50, YEAR) |
+-----+-----+
| 1944 | 1945 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT CONVERT(66.35, YEAR), CONVERT(66.50, YEAR);
+-----+-----+
| CONVERT(66.35, YEAR) | CONVERT(66.50, YEAR) |
+-----+-----+
| 2066 | 2067 |
+-----+-----+
1 row in set (0.00 sec)
```

- An argument of type `GEOMETRY` cannot be converted to `YEAR`.

- For a value that cannot be successfully converted to `YEAR`, return `NULL`.

A string value containing non-numeric characters which must be truncated prior to conversion raises a warning, as shown here:

```
mysql> SELECT CONVERT("1979aaa", YEAR);
+-----+
| CONVERT("1979aaa", YEAR) |
+-----+
| 1979 |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect YEAR value: '1979aaa' |
+-----+-----+-----+
```

12.12 XML Functions

Table 12.16 XML Functions

Name	Description
<code>ExtractValue()</code>	Extract a value from an XML string using XPath notation
<code>UpdateXML()</code>	Return replaced XML fragment

This section discusses XML and related functionality in MySQL.

Note

It is possible to obtain XML-formatted output from MySQL in the `mysql` and `mysqldump` clients by invoking them with the `--xml` option. See [Section 4.5.1, “mysql — The MySQL Command-Line Client”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

Two functions providing basic XPath 1.0 (XML Path Language, version 1.0) capabilities are available. Some basic information about XPath syntax and usage is provided later in this section; however, an in-depth discussion of these topics is beyond the scope of this manual, and you should refer to the [XML Path Language \(XPath\) 1.0 standard](#) for definitive information. A useful resource for those new to XPath or who desire a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Note

These functions remain under development. We continue to improve these and other aspects of XML and XPath functionality in MySQL 8.0 and onwards. You may discuss these, ask questions about them, and obtain help from other users with them in the [MySQL XML User Forum](#).

XPath expressions used with these functions support user variables and local stored program variables. User variables are weakly checked; variables local to stored programs are strongly checked (see also Bug #26518):

- **User variables (weak checking).** Variables using the syntax `$_variable_name` (that is, user variables) are not checked. No warnings or errors are issued by the server if a variable has the wrong type or has previously not been assigned a value. This also means the user is fully responsible for any typographical errors, since no warnings will be given if (for example) `$_myvariable` is used where `$@myvariable` was intended.

Example:

```
mysql> SET @xml = '<a><b>X</b><b>Y</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @i = 1, @j = 2;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @i, ExtractValue(@xml, '//b[$@i]');
+-----+-----+
| @i    | ExtractValue(@xml, '//b[$@i]') |
+-----+-----+
| 1     | X                               |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @j, ExtractValue(@xml, '//b[$@j]');
+-----+-----+
| @j    | ExtractValue(@xml, '//b[$@j]') |
+-----+-----+
| 2     | Y                               |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @k, ExtractValue(@xml, '//b[$@k]');
+-----+-----+
| @k    | ExtractValue(@xml, '//b[$@k]') |
+-----+-----+
| NULL  |                                |
+-----+-----+
1 row in set (0.00 sec)
```

- **Variables in stored programs (strong checking).** Variables using the syntax `$variable_name` can be declared and used with these functions when they are called inside stored programs. Such variables are local to the stored program in which they are defined, and are strongly checked for type and value.

Example:

```
mysql> DELIMITER |

mysql> CREATE PROCEDURE myproc ()
-> BEGIN
->   DECLARE i INT DEFAULT 1;
->   DECLARE xml VARCHAR(25) DEFAULT '<a>X</a><a>Y</a><a>Z</a>';
->
->   WHILE i < 4 DO
->     SELECT xml, i, ExtractValue(xml, '//a[$i]');
->     SET i = i+1;
->   END WHILE;
-> END |
Query OK, 0 rows affected (0.01 sec)

mysql> DELIMITER ;

mysql> CALL myproc();
+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 1 | X                             |
+-----+-----+-----+
1 row in set (0.00 sec)

+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 2 | Y                             |
+-----+-----+-----+
1 row in set (0.01 sec)

+-----+-----+-----+
| xml          | i | ExtractValue(xml, '//a[$i]') |
+-----+-----+-----+
```

```

+-----+-----+-----+
| <a>X</a><a>Y</a><a>Z</a> | 3 | Z |
+-----+-----+-----+
1 row in set (0.01 sec)

```

Parameters. Variables used in XPath expressions inside stored routines that are passed in as parameters are also subject to strong checking.

Expressions containing user variables or variables local to stored programs must otherwise (except for notation) conform to the rules for XPath expressions containing variables as given in the XPath 1.0 specification.

Note

A user variable used to store an XPath expression is treated as an empty string. Because of this, it is not possible to store an XPath expression as a user variable. (Bug #32911)

- `ExtractValue(xml_frag, xpath_expr)`

`ExtractValue()` takes two string arguments, a fragment of XML markup *xml_frag* and an XPath expression *xpath_expr* (also known as a *locator*); it returns the text (CDATA) of the first text node which is a child of the element or elements matched by the XPath expression.

Using this function is the equivalent of performing a match using the *xpath_expr* after appending `/text()`. In other words, `ExtractValue('<a>Sakila', '/a/b')` and `ExtractValue('<a>Sakila', '/a/b/text()')` produce the same result.

If multiple matches are found, the content of the first child text node of each matching element is returned (in the order matched) as a single, space-delimited string.

If no matching text node is found for the expression (including the implicit `/text()`)—for whatever reason, as long as *xpath_expr* is valid, and *xml_frag* consists of elements which are properly nested and closed—an empty string is returned. No distinction is made between a match on an empty element and no match at all. This is by design.

If you need to determine whether no matching element was found in *xml_frag* or such an element was found but contained no child text nodes, you should test the result of an expression that uses the XPath `count()` function. For example, both of these statements return an empty string, as shown here:

```

mysql> SELECT ExtractValue('<a><b></b></a>', '/a/b');
+-----+
| ExtractValue('<a><b></b></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a><c></c></a>', '/a/b');
+-----+
| ExtractValue('<a><c></c></a>', '/a/b') |
+-----+
|                                     |
+-----+
1 row in set (0.00 sec)

```

However, you can determine whether there was actually a matching element using the following:

```

mysql> SELECT ExtractValue('<a><b></b></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><b></b></a>', 'count(/a/b)') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

```

```
mysql> SELECT ExtractValue('<a><c/></a>', 'count(/a/b)');
+-----+
| ExtractValue('<a><c/></a>', 'count(/a/b)') |
+-----+
| 0 |
+-----+
1 row in set (0.01 sec)
```

Important

`ExtractValue()` returns only `CDATA`, and does not return any tags that might be contained within a matching tag, nor any of their content (see the result returned as `val1` in the following example).

```
mysql> SELECT
->   ExtractValue('<a>ccc<b>ddd</b></a>', '/a') AS val1,
->   ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b') AS val2,
->   ExtractValue('<a>ccc<b>ddd</b></a>', '//b') AS val3,
->   ExtractValue('<a>ccc<b>ddd</b></a>', '/b') AS val4,
->   ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;

+-----+-----+-----+-----+-----+
| val1 | val2 | val3 | val4 | val5 |
+-----+-----+-----+-----+-----+
| ccc  | ddd  | ddd  |      | ddd eee |
+-----+-----+-----+-----+-----+
```

This function uses the current SQL collation for making comparisons with `contains()`, performing the same collation aggregation as other string functions (such as `CONCAT()`), in taking into account the collation coercibility of their arguments; see [Section 10.8.4, “Collation Coercibility in Expressions”](#), for an explanation of the rules governing this behavior.

(Previously, binary—that is, case-sensitive—comparison was always used.)

`NULL` is returned if `xml_frag` contains elements which are not properly nested or closed, and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b>', '//a');
+-----+
| ExtractValue('<a>c</a><b>', '//a') |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
        END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c |
+-----+
1 row in set (0.00 sec)
```

- `UpdateXML(xml_target, xpath_expr, new_xml)`

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user.

If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

```
mysql> SELECT
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
->   UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
->   UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
-> \G

***** 1. row *****
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
```

Note

A discussion in depth of XPath syntax and usage are beyond the scope of this manual. Please see the [XML Path Language \(XPath\) 1.0 specification](#) for definitive information. A useful resource for those new to XPath or who are wishing a refresher in the basics is the [Zvon.org XPath Tutorial](#), which is available in several languages.

Descriptions and examples of some basic XPath expressions follow:

- `/tag`

Matches `<tag/>` if and only if `<tag/>` is the root element.

Example: `/a` has a match in `<a>` because it matches the outermost (root) tag. It does not match the inner `a` element in `<a>` because in this instance it is the child of another element.

- `/tag1/tag2`

Matches `<tag2/>` if and only if it is a child of `<tag1/>`, and `<tag1/>` is the root element.

Example: `/a/b` matches the `b` element in the XML fragment `<a>` because it is a child of the root element `a`. It does not have a match in `<a>` because in this case, `b` is the root element (and hence the child of no other element). Nor does the XPath expression have a match in `<a><c></c>`; here, `b` is a descendant of `a`, but not actually a child of `a`.

This construct is extendable to three or more elements. For example, the XPath expression `/a/b/c` matches the `c` element in the fragment `<a><c></c>`.

- `//tag`

Matches any instance of `<tag>`.

Example: `//a` matches the `a` element in any of the following: `<a><c></c>`; `<c><a></c>`; `<c><a></c>`.

`//` can be combined with `/`. For example, `//a/b` matches the `b` element in either of the fragments `<a>` or `<c><a></c>`.

**Note**

`//tag` is the equivalent of `/descendant-or-self::*//tag`. A common error is to confuse this with `/descendant-or-self::tag`, although the latter expression can actually lead to very different results, as can be seen here:

```
mysql> SET @xml = '<a><b><c>w</c><b>x</b><d>y</d>z</b></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @xml;
+-----+
| @xml                                     |
+-----+
| <a><b><c>w</c><b>x</b><d>y</d>z</b></a>      |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[1]');
+-----+
| ExtractValue(@xml, '//b[1]')           |
+-----+
| x z                                     |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//b[2]');
+-----+
| ExtractValue(@xml, '//b[2]')           |
+-----+
|                                         |
+-----+
1 row in set (0.01 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[1]') |
+-----+
| x z                                             |
+-----+
1 row in set (0.06 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::*b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::*b[2]') |
+-----+
|                                         |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[1]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[1]') |
+-----+
| z                                             |
+-----+
1 row in set (0.00 sec)

mysql> SELECT ExtractValue(@xml, '/descendant-or-self::b[2]');
+-----+
| ExtractValue(@xml, '/descendant-or-self::b[2]') |
+-----+
| x                                             |
+-----+
1 row in set (0.00 sec)
```

- The `*` operator acts as a “wildcard” that matches any element. For example, the expression `/*b` matches the `b` element in either of the XML fragments `<a>` or `<c></c>`. However,

the expression does not produce a match in the fragment `<a/>` because `b` must be a child of some other element. The wildcard may be used in any position: The expression `/*/b/*` will match any child of a `b` element that is itself not the root element.

- You can match any of several locators using the `|` (UNION) operator. For example, the expression `//b|//c` matches all `b` and `c` elements in the XML target.
- It is also possible to match an element based on the value of one or more of its attributes. This done using the syntax `tag[@attribute="value"]`. For example, the expression `//b[@id="idB"]` matches the second `b` element in the fragment `<a><b id="idA"/><c/><b id="idB"/>`. To match against any element having `attribute="value"`, use the XPath expression `//*[attribute="value"]`.

To filter multiple attribute values, simply use multiple attribute-comparison clauses in succession. For example, the expression `//b[@c="x"][@d="y"]` matches the element `<b c="x" d="y"/>` occurring anywhere in a given XML fragment.

To find elements for which the same attribute matches any of several values, you can use multiple locators joined by the `|` operator. For example, to match all `b` elements whose `c` attributes have either of the values 23 or 17, use the expression `//b[@c="23"]|//b[@c="17"]`. You can also use the logical `or` operator for this purpose: `//b[@c="23" or @c="17"]`.

Note

The difference between `or` and `|` is that `or` joins conditions, while `|` joins result sets.

XPath Limitations. The XPath syntax supported by these functions is currently subject to the following limitations:

- Nodeset-to-nodeset comparison (such as `'/a/b[@c=@d]'`) is not supported.
- All of the standard XPath comparison operators are supported. (Bug #22823)
- Relative locator expressions are resolved in the context of the root node. For example, consider the following query and result:

```
mysql> SELECT ExtractValue(
->   '<a><b c="1">X</b><b c="2">Y</b></a>',
->   'a/b'
-> ) AS result;
+-----+
| result |
+-----+
| X Y    |
+-----+
1 row in set (0.03 sec)
```

In this case, the locator `a/b` resolves to `/a/b`.

Relative locators are also supported within predicates. In the following example, `d[../@c="1"]` is resolved as `/a/b[d[../@c="1"]]`:

```
mysql> SELECT ExtractValue(
->   '<a>
->     <b c="1"><d>X</d></b>
->     <b c="2"><d>X</d></b>
->   </a>',
->   'a/b[d[../@c="1"]]'
-> ) AS result;
+-----+
| result |
+-----+
| X      |
+-----+
1 row in set (0.00 sec)
```

- Locators prefixed with expressions that evaluate as scalar values—including variable references, literals, numbers, and scalar function calls—are not permitted, and their use results in an error.
- The `::` operator is not supported in combination with node types such as the following:

- `axis::comment()`
- `axis::text()`
- `axis::processing-instructions()`
- `axis::node()`

However, name tests (such as `axis::name` and `axis::*`) are supported, as shown in these examples:

```
mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::b');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::b') |
+-----+
| x |
+-----+
1 row in set (0.02 sec)

mysql> SELECT ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*');
+-----+
| ExtractValue('<a><b>x</b><c>y</c></a>', '/a/child::*') |
+-----+
| x y |
+-----+
1 row in set (0.01 sec)
```

- “Up-and-down” navigation is not supported in cases where the path would lead “above” the root element. That is, you cannot use expressions which match on descendants of ancestors of a given element, where one or more of the ancestors of the current element is also an ancestor of the root element (see Bug #16321).
- The following XPath functions are not supported, or have known issues as indicated:
 - `id()`
 - `lang()`
 - `local-name()`
 - `name()`
 - `namespace-uri()`
 - `normalize-space()`
 - `starts-with()`
 - `string()`
 - `substring-after()`
 - `substring-before()`
 - `translate()`

- The following axes are not supported:

- `following-sibling`
- `following`
- `preceding-sibling`
- `preceding`

XPath expressions passed as arguments to `ExtractValue()` and `UpdateXML()` may contain the colon character (:) in element selectors, which enables their use with markup employing XML namespaces notation. For example:

```
mysql> SET @xml = '<a>111<b:c>222<d>333</d><e:f>444</e:f></b:c></a>';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT ExtractValue(@xml, '//e:f');
+-----+
| ExtractValue(@xml, '//e:f') |
+-----+
| 444                          |
+-----+
1 row in set (0.00 sec)

mysql> SELECT UpdateXML(@xml, '//b:c', '<g:h>555</g:h>');
+-----+
| UpdateXML(@xml, '//b:c', '<g:h>555</g:h>') |
+-----+
| <a>111<g:h>555</g:h></a>                  |
+-----+
1 row in set (0.00 sec)
```

This is similar in some respects to what is permitted by [Apache Xalan](#) and some other parsers, and is much simpler than requiring namespace declarations or the use of the `namespace-uri()` and `local-name()` functions.

Error handling. For both `ExtractValue()` and `UpdateXML()`, the XPath locator used must be valid and the XML to be searched must consist of elements which are properly nested and closed. If the locator is invalid, an error is generated:

```
mysql> SELECT ExtractValue('<a>c</a><b/>', '//&a');
ERROR 1105 (HY000): XPATH syntax error: '&a'
```

If `xml_frag` does not consist of elements which are properly nested and closed, `NULL` is returned and a warning is generated, as shown in this example:

```
mysql> SELECT ExtractValue('<a>c</a><b', '//a');
+-----+
| ExtractValue('<a>c</a><b', '//a') |
+-----+
| NULL                          |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1525
Message: Incorrect XML value: 'parse error at line 1 pos 11:
        END-OF-INPUT unexpected ('>' wanted)'
1 row in set (0.00 sec)

mysql> SELECT ExtractValue('<a>c</a><b/>', '//a');
+-----+
| ExtractValue('<a>c</a><b/>', '//a') |
+-----+
| c                          |
+-----+
```

1 row in set (0.00 sec)

Important

The replacement XML used as the third argument to `UpdateXML()` is *not* checked to determine whether it consists solely of elements which are properly nested and closed.

XPath Injection. *code injection* occurs when malicious code is introduced into the system to gain unauthorized access to privileges and data. It is based on exploiting assumptions made by developers about the type and content of data input from users. XPath is no exception in this regard.

A common scenario in which this can happen is the case of application which handles authorization by matching the combination of a login name and password with those found in an XML file, using an XPath expression like this one:

```
//user[login/text()='neapolitan' and password/text()='lc3cr34m']/attribute::id
```

This is the XPath equivalent of an SQL statement like this one:

```
SELECT id FROM users WHERE login='neapolitan' AND password='lc3cr34m';
```

A PHP application employing XPath might handle the login process like this:

```
<?php
    $file      = "users.xml";

    $login     = $_POST["login"];
    $password  = $_POST["password"];

    $xpath = "//user[login/text()=$login and password/text()=$password]/attribute::id";

    if( file_exists($file) )
    {
        $xml = simplexml_load_file($file);

        if($result = $xml->xpath($xpath))
            echo "You are now logged in as user $result[0].";
        else
            echo "Invalid login name or password.";
    }
    else
        exit("Failed to open $file.");
?>
```

No checks are performed on the input. This means that a malevolent user can “short-circuit” the test by entering ' or 1=1 for both the login name and password, resulting in `$xpath` being evaluated as shown here:

```
//user[login/text()=' ' or 1=1 and password/text()=' ' or 1=1]/attribute::id
```

Since the expression inside the square brackets always evaluates as `true`, it is effectively the same as this one, which matches the `id` attribute of every `user` element in the XML document:

```
//user/attribute::id
```

One way in which this particular attack can be circumvented is simply by quoting the variable names to be interpolated in the definition of `$xpath`, forcing the values passed from a Web form to be converted to strings:

```
$xpath = "//user[login/text()='$_login' and password/text()='$_password']/attribute::id";
```

This is the same strategy that is often recommended for preventing SQL injection attacks. In general, the practices you should follow for preventing XPath injection attacks are the same as for preventing SQL injection:

- Never accepted untested data from users in your application.
- Check all user-submitted data for type; reject or convert data that is of the wrong type
- Test numeric data for out of range values; truncate, round, or reject values that are out of range. Test strings for illegal characters and either strip them out or reject input containing them.
- Do not output explicit error messages that might provide an unauthorized user with clues that could be used to compromise the system; log these to a file or database table instead.

Just as SQL injection attacks can be used to obtain information about database schemas, so can XPath injection be used to traverse XML files to uncover their structure, as discussed in Amit Klein's paper [Blind XPath Injection](#) (PDF file, 46KB).

It is also important to check the output being sent back to the client. Consider what can happen when we use the MySQL `ExtractValue()` function:

```
mysql> SELECT ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
-> ) AS id;
+-----+
| id                |
+-----+
| 00327 13579 02403 42354 28570 |
+-----+
1 row in set (0.01 sec)
```

Because `ExtractValue()` returns multiple matches as a single space-delimited string, this injection attack provides every valid ID contained within `users.xml` to the user as a single row of output. As an extra safeguard, you should also test output before returning it to the user. Here is a simple example:

```
mysql> SELECT @id = ExtractValue(
->     LOAD_FILE('users.xml'),
->     '//user[login/text()="" or 1=1 and password/text()="" or 1=1]/attribute::id'
-> );
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT IF(
->     INSTR(@id, ' ') = 0,
->     @id,
->     'Unable to retrieve user ID')
-> AS singleID;
+-----+
| singleID                |
+-----+
| Unable to retrieve user ID |
+-----+
1 row in set (0.00 sec)
```

In general, the guidelines for returning data to users securely are the same as for accepting user input. These can be summed up as:

- Always test outgoing data for type and permissible values.
- Never permit unauthorized users to view error messages that might provide information about the application that could be used to exploit it.

12.13 Bit Functions and Operators

Table 12.17 Bit Functions and Operators

Name	Description
&	Bitwise AND

Name	Description
>>	Right shift
<<	Left shift
^	Bitwise XOR
<code>BIT_COUNT()</code>	Return the number of bits that are set
	Bitwise OR
~	Bitwise inversion

Bit functions and operators comprise `BIT_COUNT()`, `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`, `&`, `|`, `^`, `~`, `<<`, and `>>`. (The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions are described in [Section 12.20.1, “Aggregate Function Descriptions”](#).) Prior to MySQL 8.0, bit functions and operators required `BIGINT` (64-bit integer) arguments and returned `BIGINT` values, so they had a maximum range of 64 bits. Non-`BIGINT` arguments were converted to `BIGINT` prior to performing the operation and truncation could occur.

In MySQL 8.0, bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types) and return a value of like type, which enables them to take arguments and produce return values larger than 64 bits. Nonbinary string arguments are converted to `BIGINT` and processed as such, as before.

An implication of this change in behavior is that bit operations on binary string arguments might produce a different result in MySQL 8.0 than in 5.7. For information about how to prepare in MySQL 5.7 for potential incompatibilities between MySQL 5.7 and 8.0, see [Bit Functions and Operators](#), in [MySQL 5.7 Reference Manual](#).

- [Bitwise Complement and Shift Operations](#)
- [BIT_COUNT\(\) Operations](#)
- [BIT_AND\(\), BIT_OR\(\), and BIT_XOR\(\) Operations](#)
- [Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals](#)
- [Bit-Operation Incompatibilities with MySQL 5.7](#)

Bit Operations Prior to MySQL 8.0

Bit operations prior to MySQL 8.0 handle only unsigned 64-bit integer argument and result values (that is, unsigned `BIGINT` values). Conversion of arguments of other types to `BIGINT` occurs as necessary. Examples:

- This statement operates on numeric literals, treated as unsigned 64-bit integers:

```
mysql> SELECT 127 | 128, 128 << 2, BIT_COUNT(15);
+-----+-----+-----+
| 127 | 128 | 128 << 2 | BIT_COUNT(15) |
+-----+-----+-----+
|      255 |      512 |      4 |
+-----+-----+-----+
```

- This statement performs to-number conversions on the string arguments ('127' to 127, and so forth) before performing the same operations as the first statement and producing the same results:

```
mysql> SELECT '127' | '128', '128' << 2, BIT_COUNT('15');
+-----+-----+-----+
| '127' | '128' | '128' << 2 | BIT_COUNT('15') |
+-----+-----+-----+
|      255 |      512 |           4 |
+-----+-----+-----+
```

- This statement uses hexadecimal literals for the bit-operation arguments. MySQL by default treats hexadecimal literals as binary strings, but in numeric context evaluates them as numbers (see [Section 9.1.4, “Hexadecimal Literals”](#)). Prior to MySQL 8.0, numeric context includes bit operations. Examples:

```
mysql> SELECT X'7F' | X'80', X'80' << 2, BIT_COUNT(X'0F');
+-----+-----+-----+
| X'7F' | X'80' | X'80' << 2 | BIT_COUNT(X'0F') |
+-----+-----+-----+
|      255 |      512 |           4 |
+-----+-----+-----+
```

Handling of bit-value literals in bit operations is similar to hexadecimal literals (that is, as numbers).

Bit Operations in MySQL 8.0

MySQL 8.0 extends bit operations to handle binary string arguments directly (without conversion) and produce binary string results. (Arguments that are not integers or binary strings are still converted to integers, as before.) This extension enhances bit operations in the following ways:

- Bit operations become possible on values longer than 64 bits.
- It is easier to perform bit operations on values that are more naturally represented as binary strings than as integers.

For example, consider UUID values and IPv6 addresses, which have human-readable text formats like this:

```
UUID: 6ccd780c-baba-1026-9564-5b8c656024db
IPv6: fe80::219:d1ff:fe91:1a72
```

It is cumbersome to operate on text strings in those formats. An alternative is convert them to fixed-length binary strings without delimiters. `UUID_TO_BIN()` and `INET6_ATON()` each produce a value of data type `BINARY(16)`, a binary string 16 bytes (128 bits) long. The following statements illustrate this (`HEX()` is used to produce displayable values):

```
mysql> SELECT HEX(UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db'));
+-----+
| HEX(UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db')) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
mysql> SELECT HEX(INET6_ATON('fe80::219:d1ff:fe91:1a72'));
+-----+
| HEX(INET6_ATON('fe80::219:d1ff:fe91:1a72')) |
+-----+
| FE800000000000000219D1FFFE911A72 |
+-----+
```

Those binary values are easily manipulable with bit operations to perform actions such as extracting the timestamp from UUID values, or extracting the network and host parts of IPv6 addresses. (For examples, see later in this discussion.)

Arguments that count as binary strings include column values, routine parameters, local variables, and user-defined variables that have a binary string type: `BINARY`, `VARBINARY`, or one of the `BLOB` types.

What about hexadecimal literals and bit literals? Recall that those are binary strings by default in MySQL, but numbers in numeric context. How are they handled for bit operations in MySQL 8.0?

Does MySQL continue to evaluate them in numeric context, as is done prior to MySQL 8.0? Or do bit operations evaluate them as binary strings, now that binary strings can be handled “natively” without conversion?

Answer: It has been common to specify arguments to bit operations using hexadecimal literals or bit literals with the intent that they represent numbers, so MySQL continues to evaluate bit operations in numeric context when all bit arguments are hexadecimal or bit literals, for backward compatibility. If you require evaluation as binary strings instead, that is easily accomplished: Use the `_binary` introducer for at least one literal.

- These bit operations evaluate the hexadecimal literals and bit literals as integers:

```
mysql> SELECT X'40' | X'01', b'11110001' & b'01001111';
+-----+-----+
| X'40' | X'01' | b'11110001' & b'01001111' |
+-----+-----+
|          65 |          65 |
+-----+-----+
```

- These bit operations evaluate the hexadecimal literals and bit literals as binary strings, due to the `_binary` introducer:

```
mysql> SELECT _binary X'40' | X'01', b'11110001' & _binary b'01001111';
+-----+-----+
| _binary X'40' | X'01' | b'11110001' & _binary b'01001111' |
+-----+-----+
| A             | A             |
+-----+-----+
```

Although the bit operations in both statements produce a result with a numeric value of 65, the second statement operates in binary-string context, for which 65 is ASCII `A`.

In numeric evaluation context, permitted values of hexadecimal literal and bit literal arguments have a maximum of 64 bits, as do results. By contrast, in binary-string evaluation context, permitted arguments (and results) can exceed 64 bits:

```
mysql> SELECT _binary X'4040404040404040' | X'0102030405060708';
+-----+-----+
| _binary X'4040404040404040' | X'0102030405060708' |
+-----+-----+
| ABCDEFGH                     |                       |
+-----+-----+
```

There are several ways to refer to a hexadecimal literal or bit literal in a bit operation to cause binary-string evaluation:

```
_binary literal
BINARY literal
CAST(literal AS BINARY)
```

Another way to produce binary-string evaluation of hexadecimal literals or bit literals is to assign them to user-defined variables, which results in variables that have a binary string type:

```
mysql> SET @v1 = X'40', @v2 = X'01', @v3 = b'11110001', @v4 = b'01001111';
mysql> SELECT @v1 | @v2, @v3 & @v4;
+-----+-----+
| @v1 | @v2 | @v3 & @v4 |
+-----+-----+
| A    | A    |           |
+-----+-----+
```

In binary-string context, bitwise operation arguments must have the same length or an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs:

```
mysql> SELECT _binary X'40' | X'0001';
ERROR 3513 (HY000): Binary operands of bitwise
```

operators must be of equal length

To satisfy the equal-length requirement, pad the shorter value with leading zero digits or, if the longer value begins with leading zero digits and a shorter result value is acceptable, strip them:

```
mysql> SELECT _binary X'0040' | X'0001';
+-----+
| _binary X'0040' | X'0001' |
+-----+
| A              |
+-----+
mysql> SELECT _binary X'40' | X'01';
+-----+
| _binary X'40' | X'01' |
+-----+
| A            |
+-----+
```

Padding or stripping can also be accomplished using functions such as `LPAD()`, `RPAD()`, `SUBSTR()`, or `CAST()`. In such cases, the expression arguments are no longer all literals and `_binary` becomes unnecessary. Examples:

```
mysql> SELECT LPAD(X'40', 2, X'00') | X'0001';
+-----+
| LPAD(X'40', 2, X'00') | X'0001' |
+-----+
| A                    |
+-----+
mysql> SELECT X'40' | SUBSTR(X'0001', 2, 1);
+-----+
| X'40' | SUBSTR(X'0001', 2, 1) |
+-----+
| A    |
+-----+
```

Binary String Bit-Operation Examples

The following example illustrates use of bit operations to extract parts of a UUID value, in this case, the timestamp and IEEE 802 node number. This technique requires bitmasks for each extracted part.

Convert the text UUID to the corresponding 16-byte binary value so that it can be manipulated using bit operations in binary-string context:

```
mysql> SET @uuid = UUID_TO_BIN('6ccd780c-baba-1026-9564-5b8c656024db');
mysql> SELECT HEX(@uuid);
+-----+
| HEX(@uuid) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
```

Construct bitmasks for the timestamp and node number parts of the value. The timestamp comprises the first three parts (64 bits, bits 0 to 63) and the node number is the last part (48 bits, bits 80 to 127):

```
mysql> SET @ts_mask = CAST(X'FFFFFFFFFFFFFFFF' AS BINARY(16));
mysql> SET @node_mask = CAST(X'FFFFFFFFFFFF' AS BINARY(16)) >> 80;
mysql> SELECT HEX(@ts_mask);
+-----+
| HEX(@ts_mask) |
+-----+
| FFFFFFFFFFFFFFFF0000000000000000 |
+-----+
mysql> SELECT HEX(@node_mask);
+-----+
| HEX(@node_mask) |
+-----+
| 000000000000000000000000FFFFFFFF |
+-----+
```

The `CAST(... AS BINARY(16))` function is used here because the masks must be the same length as the UUID value against which they are applied. The same result can be produced using other functions to pad the masks to the required length:

```
SET @ts_mask= RPAD(X'FFFFFFFFFFFFFFFF', 16, X'00');
SET @node_mask = LPAD(X'FFFFFFFFFFFFFFFF', 16, X'00');
```

Use the masks to extract the timestamp and node number parts:

```
mysql> SELECT HEX(@uuid & @ts_mask) AS 'timestamp part';
+-----+
| timestamp part |
+-----+
| 6CCD780CBABA10260000000000000000 |
+-----+
mysql> SELECT HEX(@uuid & @node_mask) AS 'node part';
+-----+
| node part |
+-----+
| 0000000000000000000000005B8C656024DB |
+-----+
```

The preceding example uses these bit operations: right shift (`>>`) and bitwise AND (`&`).

Note

`UUID_TO_BIN()` takes a flag that causes some bit rearrangement in the resulting binary UUID value. If you use that flag, modify the extraction masks accordingly.

The next example uses bit operations to extract the network and host parts of an IPv6 address. Suppose that the network part has a length of 80 bits. Then the host part has a length of $128 - 80 = 48$ bits. To extract the network and host parts of the address, convert it to a binary string, then use bit operations in binary-string context.

Convert the text IPv6 address to the corresponding binary string:

```
mysql> SET @ip = INET6_ATON('fe80::219:d1ff:fe91:1a72');
```

Define the network length in bits:

```
mysql> SET @net_len = 80;
```

Construct network and host masks by shifting the all-ones address left or right. To do this, begin with the address `::`, which is shorthand for all zeros, as you can see by converting it to a binary string like this:

```
mysql> SELECT HEX(INET6_ATON('::')) AS 'all zeros';
+-----+
| all zeros |
+-----+
| 00000000000000000000000000000000 |
+-----+
```

To produce the complementary value (all ones), use the `~` operator to invert the bits:

```
mysql> SELECT HEX(~INET6_ATON('::')) AS 'all ones';
+-----+
| all ones |
+-----+
| FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF |
+-----+
```

Shift the all-ones value left or right to produce the network and host masks:

```
mysql> SET @net_mask = ~INET6_ATON('::') << (128 - @net_len);
```

```
mysql> SET @host_mask = ~INET6_ATON('::') >> @net_len;
```

Display the masks to verify that they cover the correct parts of the address:

```
mysql> SELECT INET6_NTOA(@net_mask) AS 'network mask';
+-----+
| network mask |
+-----+
| ffff:ffff:ffff:ffff:ffff:: |
+-----+
mysql> SELECT INET6_NTOA(@host_mask) AS 'host mask';
+-----+
| host mask |
+-----+
| ::ffff:255.255.255.255 |
+-----+
```

Extract and display the network and host parts of the address:

```
mysql> SET @net_part = @ip & @net_mask;
mysql> SET @host_part = @ip & @host_mask;
mysql> SELECT INET6_NTOA(@net_part) AS 'network part';
+-----+
| network part |
+-----+
| fe80::219:0:0:0 |
+-----+
mysql> SELECT INET6_NTOA(@host_part) AS 'host part';
+-----+
| host part |
+-----+
| ::d1ff:fe91:1a72 |
+-----+
```

The preceding example uses these bit operations: Complement (~), left shift (<<), and bitwise AND (&).

The remaining discussion provides details on argument handling for each group of bit operations, more information about literal-value handling in bit operations, and potential incompatibilities between MySQL 8.0 and older MySQL versions.

Bitwise AND, OR, and XOR Operations

For &, |, and ^ bit operations, the result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

Examples of numeric evaluation:

```
mysql> SELECT 64 | 1, X'40' | X'01';
+-----+
| 64 | 1 | X'40' | X'01' |
+-----+
| 65 | 65 |
+-----+
```

Examples of binary-string evaluation:

```
mysql> SELECT _binary X'40' | X'01';
+-----+
```

```

| _binary X'40' | X'01' |
+-----+
| A             |
+-----+
mysql> SET @var1 = X'40', @var2 = X'01';
mysql> SELECT @var1 | @var2;
+-----+
| @var1 | @var2 |
+-----+
| A     |       |
+-----+

```

Bitwise Complement and Shift Operations

For `~`, `<<`, and `>>` bit operations, the result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For shift operations, bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

Examples of numeric evaluation:

```

mysql> SELECT ~0, 64 << 2, X'40' << 2;
+-----+-----+-----+
| ~0          | 64 << 2 | X'40' << 2 |
+-----+-----+-----+
| 18446744073709551615 |      256 |      256 |
+-----+-----+-----+

```

Examples of binary-string evaluation:

```

mysql> SELECT HEX(_binary X'1111000022220000' >> 16);
+-----+
| HEX(_binary X'1111000022220000' >> 16) |
+-----+
| 0000111100002222                        |
+-----+
mysql> SELECT HEX(_binary X'1111000022220000' << 16);
+-----+
| HEX(_binary X'1111000022220000' << 16) |
+-----+
| 0000222200000000                        |
+-----+
mysql> SET @var1 = X'F0F0F0F0';
mysql> SELECT HEX(~@var1);
+-----+
| HEX(~@var1) |
+-----+
| 0F0F0F0F    |
+-----+

```

BIT_COUNT() Operations

The `BIT_COUNT()` function always returns an unsigned 64-bit integer, or `NULL` if the argument is `NULL`.

```

mysql> SELECT BIT_COUNT(127);
+-----+
| BIT_COUNT(127) |
+-----+

```

```

+-----+
|          7 |
+-----+
mysql> SELECT BIT_COUNT(b'010101'), BIT_COUNT(_binary b'010101');
+-----+-----+
| BIT_COUNT(b'010101') | BIT_COUNT(_binary b'010101') |
+-----+-----+
|          3 |          3 |
+-----+-----+

```

BIT_AND(), BIT_OR(), and BIT_XOR() Operations

For the `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` bit functions, the result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the length of the argument values (all bits 1 for `BIT_AND()`, all bits 0 for `BIT_OR()`, and `BIT_XOR()`).

Example:

```

mysql> CREATE TABLE t (group_id INT, a VARBINARY(6));
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (1, NULL);
mysql> INSERT INTO t VALUES (2, NULL);
mysql> INSERT INTO t VALUES (2, X'1234');
mysql> INSERT INTO t VALUES (2, X'FF34');
mysql> SELECT HEX(BIT_AND(a)), HEX(BIT_OR(a)), HEX(BIT_XOR(a))
        FROM t GROUP BY group_id;
+-----+-----+-----+
| HEX(BIT_AND(a)) | HEX(BIT_OR(a)) | HEX(BIT_XOR(a)) |
+-----+-----+-----+
| FFFFFFFF | 000000000000 | 000000000000 |
| 1234 | FF34 | ED00 |
+-----+-----+-----+

```

Special Handling of Hexadecimal Literals, Bit Literals, and NULL Literals

For backward compatibility, MySQL 8.0 evaluates bit operations in numeric context when all bit arguments are hexadecimal literals, bit literals, or `NULL` literals. That is, bit operations on binary-string bit arguments do not use binary-string evaluation if all bit arguments are unadorned hexadecimal literals, bit literals, or `NULL` literals. (This does not apply to such literals if they are written with a `_binary` introducer, `BINARY` operator, or other way of specifying them explicitly as binary strings.)

The literal handling just described is the same as prior to MySQL 8.0. Examples:

- These bit operations evaluate the literals in numeric context and produce a `BIGINT` result:

```

b'0001' | b'0010'
X'0008' << 8

```

- These bit operations evaluate `NULL` in numeric context and produce a `BIGINT` result that has a `NULL` value:

```

NULL & NULL

```

```
NULL >> 4
```

In MySQL 8.0, you can cause those operations to evaluate the arguments in binary-string context by indicating explicitly that at least one argument is a binary string:

```
_binary b'0001' | b'0010'
_binary X'0008' << 8
BINARY NULL & NULL
BINARY NULL >> 4
```

The result of the last two expressions is `NULL`, just as without the `BINARY` operator, but the data type of the result is a binary string type rather than an integer type.

Bit-Operation Incompatibilities with MySQL 5.7

Because bit operations can handle binary string arguments natively in MySQL 8.0, some expressions produce a different result in MySQL 8.0 than in 5.7. The five problematic expression types to watch out for are:

```
nonliteral_binary { & | ^ } binary
binary { & | ^ } nonliteral_binary
nonliteral_binary { << >> } anything
~ nonliteral_binary
AGGR_BIT_FUNC(nonliteral_binary)
```

Those expressions return `BIGINT` in MySQL 5.7, binary string in 8.0.

Explanation of notation:

- `{ op1 op2 ... }`: List of operators that apply to the given expression type.
- `binary`: Any kind of binary string argument, including a hexadecimal literal, bit literal, or `NULL` literal.
- `nonliteral_binary`: An argument that is a binary string value other than a hexadecimal literal, bit literal, or `NULL` literal.
- `AGGR_BIT_FUNC`: An aggregate function that takes bit-value arguments: `BIT_AND()`, `BIT_OR()`, `BIT_XOR()`.

For information about how to prepare in MySQL 5.7 for potential incompatibilities between MySQL 5.7 and 8.0, see [Bit Functions and Operators](#), in [MySQL 5.7 Reference Manual](#).

The following list describes available bit functions and operators:

- |

Bitwise OR.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 29 | 15;
-> 31
mysql> SELECT _binary X'40404040' | X'01020304';
-> 'ABCD'
```

- `&`

Bitwise AND.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 29 & 15;
-> 13
mysql> SELECT HEX(_binary X'FF' & b'11110000');
-> 'F0'
```

- `^`

Bitwise XOR.

The result type depends on whether the arguments are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the arguments have a binary string type, and at least one of them is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the arguments. If the arguments have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 1 ^ 1;
-> 0
mysql> SELECT 1 ^ 0;
-> 1
mysql> SELECT 11 ^ 3;
-> 8
mysql> SELECT HEX(_binary X'FEDC' ^ X'1111');
-> 'EFGD'
```

- `<<`

Shifts a longlong (`BIGINT`) number or binary string to the left.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 1 << 2;
-> 4
mysql> SELECT HEX(_binary X'00FF00FF00FF' << 8);
-> 'FF00FF00FF00'
```

- >>

Shifts a longlong ([BIGINT](#)) number or binary string to the right.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or [NULL](#) literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

Bits shifted off the end of the value are lost without warning, regardless of the argument type. In particular, if the shift count is greater or equal to the number of bits in the bit argument, all bits in the result are 0.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 4 >> 2;
-> 1
mysql> SELECT HEX(_binary X'00FF00FF00FF' >> 8);
-> '0000FF00FF00'
```

- ~

Invert all bits.

The result type depends on whether the bit argument is evaluated as a binary string or number:

- Binary-string evaluation occurs when the bit argument has a binary string type, and is not a hexadecimal literal, bit literal, or [NULL](#) literal. Numeric evaluation occurs otherwise, with argument conversion to an unsigned 64-bit integer as necessary.
- Binary-string evaluation produces a binary string of the same length as the bit argument. Numeric evaluation produces an unsigned 64-bit integer.

For more information, see the introductory discussion in this section.

```
mysql> SELECT 5 & ~1;
-> 4
mysql> SELECT HEX(~X'0000FFFF1111EEEE');
-> 'FFFF0000EEEE1111'
```

- [BIT_COUNT\(N\)](#)

Returns the number of bits that are set in the argument *N* as an unsigned 64-bit integer, or [NULL](#) if the argument is [NULL](#).

```
mysql> SELECT BIT_COUNT(64), BIT_COUNT(BINARY 64);
-> 1, 7
mysql> SELECT BIT_COUNT('64'), BIT_COUNT(_binary '64');
-> 1, 7
mysql> SELECT BIT_COUNT(X'40'), BIT_COUNT(_binary X'40');
-> 1, 1
```

12.14 Encryption and Compression Functions

Table 12.18 Encryption Functions

Name	Description
<code>AES_DECRYPT()</code>	Decrypt using AES
<code>AES_ENCRYPT()</code>	Encrypt using AES
<code>COMPRESS()</code>	Return result as a binary string
<code>MD5()</code>	Calculate MD5 checksum
<code>RANDOM_BYTES()</code>	Return a random byte vector
<code>SHA1()</code> , <code>SHA()</code>	Calculate an SHA-1 160-bit checksum
<code>SHA2()</code>	Calculate an SHA-2 checksum
<code>STATEMENT_DIGEST()</code>	Compute statement digest hash value
<code>STATEMENT_DIGEST_TEXT()</code>	Compute normalized statement digest
<code>UNCOMPRESS()</code>	Uncompress a string compressed
<code>UNCOMPRESSED_LENGTH()</code>	Return the length of a string before compression
<code>VALIDATE_PASSWORD_STRENGTH()</code>	Determine strength of password

Many encryption and compression functions return strings for which the result might contain arbitrary byte values. If you want to store these results, use a column with a `VARBINARY` or `BLOB` binary string data type. This will avoid potential problems with trailing space removal or character set conversion that would change data values, such as may occur if you use a nonbinary string data type (`CHAR`, `VARCHAR`, `TEXT`).

Some encryption functions return strings of ASCII characters: `MD5()`, `SHA()`, `SHA1()`, `SHA2()`, `STATEMENT_DIGEST()`, `STATEMENT_DIGEST_TEXT()`. Their return value is a string that has a character set and collation determined by the `character_set_connection` and `collation_connection` system variables. This is a nonbinary string unless the character set is binary.

If an application stores values from a function such as `MD5()` or `SHA1()` that returns a string of hex digits, more efficient storage and comparisons can be obtained by converting the hex representation to binary using `UNHEX()` and storing the result in a `BINARY(N)` column. Each pair of hexadecimal digits requires one byte in binary form, so the value of `N` depends on the length of the hex string. `N` is 16 for an `MD5()` value and 20 for a `SHA1()` value. For `SHA2()`, `N` ranges from 28 to 32 depending on the argument specifying the desired bit length of the result.

The size penalty for storing the hex string in a `CHAR` column is at least two times, up to eight times if the value is stored in a column that uses the `utf8` character set (where each character uses 4 bytes). Storing the string also results in slower comparisons because of the larger values and the need to take character set collation rules into account.

Suppose that an application stores `MD5()` string values in a `CHAR(32)` column:

```
CREATE TABLE md5_tbl (md5_val CHAR(32), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(MD5('abcdef'), ...);
```

To convert hex strings to more compact form, modify the application to use `UNHEX()` and `BINARY(16)` instead as follows:

```
CREATE TABLE md5_tbl (md5_val BINARY(16), ...);
INSERT INTO md5_tbl (md5_val, ...) VALUES(UNHEX(MD5('abcdef')), ...);
```

Applications should be prepared to handle the very rare case that a hashing function produces the same value for two different input values. One way to make collisions detectable is to make the hash column a primary key.

**Note**

Exploits for the MD5 and SHA-1 algorithms have become known. You may wish to consider using another one-way encryption function described in this section instead, such as `SHA2()`.

**Caution**

Passwords or other sensitive values supplied as arguments to encryption functions are sent as cleartext to the MySQL server unless an SSL connection is used. Also, such values will appear in any MySQL logs to which they are written. To avoid these types of exposure, applications can encrypt sensitive values on the client side before sending them to the server. The same considerations apply to encryption keys. To avoid exposing these, applications can use stored procedures to encrypt and decrypt values on the server side.

- `AES_DECRYPT(crypt_str,key_str[,init_vector])`

This function decrypts data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of `AES_ENCRYPT()`.

Statements that use `AES_DECRYPT()` are unsafe for statement-based replication.

- `AES_ENCRYPT(str,key_str[,init_vector])`

`AES_ENCRYPT()` and `AES_DECRYPT()` implement encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as “Rijndael.” The AES standard permits various key lengths. By default these functions implement AES with a 128-bit key length. Key lengths of 196 or 256 bits can be used, as described later. The key length is a trade off between performance and security.

`AES_ENCRYPT()` encrypts the string *str* using the key string *key_str* and returns a binary string containing the encrypted output. `AES_DECRYPT()` decrypts the encrypted string *crypt_str* using the key string *key_str* and returns the original plaintext string. If either function argument is `NULL`, the function returns `NULL`.

The *str* and *crypt_str* arguments can be any length, and padding is automatically added to *str* so it is a multiple of a block as required by block-based algorithms such as AES. This padding is automatically removed by the `AES_DECRYPT()` function. The length of *crypt_str* can be calculated using this formula:

```
16 * (trunc(string_length / 16) + 1)
```

For a key length of 128 bits, the most secure way to pass a key to the *key_str* argument is to create a truly random 128-bit value and pass it as a binary value. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text',UNHEX('F3229A0B371ED2D9441B830D21A390C3')));
```

A passphrase can be used to generate an AES key by hashing the passphrase. For example:

```
INSERT INTO t
VALUES (1,AES_ENCRYPT('text', UNHEX(SHA2('My secret passphrase',512))));
```

Do not pass a password or passphrase directly to *crypt_str*, hash it first. Previous versions of this documentation suggested the former approach, but it is no longer recommended as the examples shown here are more secure.

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

`AES_ENCRYPT()` and `AES_DECRYPT()` permit control of the block encryption mode and take an optional `init_vector` initialization vector argument:

- The `block_encryption_mode` system variable controls the mode for block-based encryption algorithms. Its default value is `aes-128-ecb`, which signifies encryption using a key length of 128 bits and ECB mode. For a description of the permitted values of this variable, see [Section 5.1.8, “Server System Variables”](#).
- The optional `init_vector` argument provides an initialization vector for block encryption modes that require it.

For modes that require the optional `init_vector` argument, it must be 16 bytes or longer (bytes in excess of 16 are ignored). An error occurs if `init_vector` is missing.

For modes that do not require `init_vector`, it is ignored and a warning is generated if it is specified.

A random string of bytes to use for the initialization vector can be produced by calling `RANDOM_BYTES(16)`. For encryption modes that require an initialization vector, the same vector must be used for encryption and decryption.

```
mysql> SET block_encryption_mode = 'aes-256-cbc';
mysql> SET @key_str = SHA2('My secret passphrase',512);
mysql> SET @init_vector = RANDOM_BYTES(16);
mysql> SET @crypt_str = AES_ENCRYPT('text',@key_str,@init_vector);
mysql> SELECT AES_DECRYPT(@crypt_str,@key_str,@init_vector);
+-----+
| AES_DECRYPT(@crypt_str,@key_str,@init_vector) |
+-----+
| text                                         |
+-----+
```

The following table lists each permitted block encryption mode and whether the initialization vector argument is required.

Block Encryption Mode	Initialization Vector Required
ECB	No
CBC	Yes
CFB1	Yes
CFB8	Yes
CFB128	Yes
OFB	Yes

Statements that use `AES_ENCRYPT()` or `AES_DECRYPT()` are unsafe for statement-based replication.

- `COMPRESS(string_to_compress)`

Compresses a string and returns the result as a binary string. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

```
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
-> 21
mysql> SELECT LENGTH(COMPRESS(''));
-> 0
mysql> SELECT LENGTH(COMPRESS('a'));
-> 13
mysql> SELECT LENGTH(COMPRESS(REPEAT('a',16)));
```

 -> 15

The compressed string contents are stored the following way:

- Empty strings are stored as empty strings.
- Nonempty strings are stored as a 4-byte length of the uncompressed string (low byte first), followed by the compressed string. If the string ends with space, an extra `.` character is added to avoid problems with endspace trimming should the result be stored in a `CHAR` or `VARCHAR` column. (However, use of nonbinary string data types such as `CHAR` or `VARCHAR` to store compressed strings is not recommended anyway because character set conversion may occur. Use a `VARBINARY` or `BLOB` binary string column instead.)
- `MD5(str)`

Calculates an MD5 128-bit checksum for the string. The value is returned as a string of 32 hexadecimal digits, or `NULL` if the argument was `NULL`. The return value can, for example, be used as a hash key. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

If FIPS mode is enabled, `MD5()` returns `NULL`. See [Section 6.8, “FIPS Support”](#).

```
mysql> SELECT MD5('testing');
-> 'ae2b1fca515949e5d54fb22b8ed95575'
```

This is the “RSA Data Security, Inc. MD5 Message-Digest Algorithm.”

See the note regarding the MD5 algorithm at the beginning this section.

- `RANDOM_BYTES(len)`

This function returns a binary string of `len` random bytes generated using the random number generator of the SSL library. Permitted values of `len` range from 1 to 1024. For values outside that range, an error occurs.

`RANDOM_BYTES()` can be used to provide the initialization vector for the `AES_DECRYPT()` and `AES_ENCRYPT()` functions. For use in that context, `len` must be at least 16. Larger values are permitted, but bytes in excess of 16 are ignored.

`RANDOM_BYTES()` generates a random value, which makes its result nondeterministic. Consequently, statements that use this function are unsafe for statement-based replication.

- `SHA1(str)`, `SHA(str)`

Calculates an SHA-1 160-bit checksum for the string, as described in RFC 3174 (Secure Hash Algorithm). The value is returned as a string of 40 hexadecimal digits, or `NULL` if the argument was `NULL`. One of the possible uses for this function is as a hash key. See the notes at the beginning of this section about storing hash values efficiently. `SHA()` is synonymous with `SHA1()`.

The return value is a string in the connection character set.

```
mysql> SELECT SHA1('abc');
-> 'a9993e364706816aba3e25717850c26c9cd0d89d'
```

`SHA1()` can be considered a cryptographically more secure equivalent of `MD5()`. However, see the note regarding the MD5 and SHA-1 algorithms at the beginning this section.

- `SHA2(str, hash_length)`

Calculates the SHA-2 family of hash functions (SHA-224, SHA-256, SHA-384, and SHA-512). The first argument is the plaintext string to be hashed. The second argument indicates the desired bit length of the result, which must have a value of 224, 256, 384, 512, or 0 (which is equivalent to 256).

If either argument is `NULL` or the hash length is not one of the permitted values, the return value is `NULL`. Otherwise, the function result is a hash value containing the desired number of bits. See the notes at the beginning of this section about storing hash values efficiently.

The return value is a string in the connection character set.

```
mysql> SELECT SHA2('abc', 224);
-> '23097d223405d8228642a477bda255b32aadbce4bda0b3f7e36c9da7'
```

This function works only if MySQL has been configured with SSL support. See [Section 6.3, “Using Encrypted Connections”](#).

`SHA2()` can be considered cryptographically more secure than `MD5()` or `SHA1()`.

- `STATEMENT_DIGEST(statement)`

Given an SQL statement as a string, returns the statement digest hash value as a string in the connection character set, or `NULL` if the argument is `NULL`. The related `STATEMENT_DIGEST_TEXT()` function returns the normalized statement digest. For information about statement digesting, see [Section 26.10, “Performance Schema Statement Digests and Sampling”](#).

Both functions use the MySQL parser to parse the statement. If parsing fails, an error occurs. The error message includes the parse error only if the statement is provided as a literal string.

The `max_digest_length` system variable determines the maximum number of bytes available to these functions for computing normalized statement digests.

```
mysql> SET @stmt = 'SELECT * FROM mytable WHERE cola = 10 AND colb = 20';
mysql> SELECT STATEMENT_DIGEST(@stmt);
+-----+
| STATEMENT_DIGEST(@stmt) |
+-----+
| 3bb95eeade896657c4526e74ff2a2862039d0a0fe8a9e7155b5fe492cbd78387 |
+-----+
mysql> SELECT STATEMENT_DIGEST_TEXT(@stmt);
+-----+
| STATEMENT_DIGEST_TEXT(@stmt) |
+-----+
| SELECT * FROM `mytable` WHERE `cola` = ? AND `colb` = ? |
+-----+
```

- `STATEMENT_DIGEST_TEXT(statement)`

Given an SQL statement as a string, returns the normalized statement digest as a string in the connection character set, or `NULL` if the argument is `NULL`. For additional discussion and examples, see the description of the related `STATEMENT_DIGEST()` function.

- `UNCOMPRESS(string_to_uncompress)`

Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is `NULL`. This function requires MySQL to have been compiled with a compression library such as `zlib`. Otherwise, the return value is always `NULL`.

```
mysql> SELECT UNCOMPRESS(COMPRESS('any string'));
-> 'any string'
mysql> SELECT UNCOMPRESS('any string');
-> NULL
```

- `UNCOMPRESSED_LENGTH(compressed_string)`

Returns the length that the compressed string had before being compressed.

```
mysql> SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
-> 30
```

- `VALIDATE_PASSWORD_STRENGTH(str)`

Given an argument representing a plaintext password, this function returns an integer to indicate how strong the password is. The return value ranges from 0 (weak) to 100 (strong).

Password assessment by `VALIDATE_PASSWORD_STRENGTH()` is done by the `validate_password` component. If that component is not installed, the function always returns 0. For information about installing `validate_password`, see [Section 6.4.3, “The Password Validation Component”](#). To examine or configure the parameters that affect password testing, check or set the system variables implemented by `validate_password`. See [Section 6.4.3.2, “Password Validation Options and Variables”](#).

The password is subjected to increasingly strict tests and the return value reflects which tests were satisfied, as shown in the following table. In addition, if the `validate_password.check_user_name` system variable is enabled and the password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.

Password Test	Return Value
Length < 4	0
Length ≥ 4 and < <code>validate_password.length</code>	25
Satisfies policy 1 (<code>LOW</code>)	50
Satisfies policy 2 (<code>MEDIUM</code>)	75
Satisfies policy 3 (<code>STRONG</code>)	100

12.15 Locking Functions

This section describes functions used to manipulate user-level locks.

Table 12.19 Locking Functions

Name	Description
<code>GET_LOCK()</code>	Get a named lock
<code>IS_FREE_LOCK()</code>	Whether the named lock is free
<code>IS_USED_LOCK()</code>	Whether the named lock is in use; return connection identifier if true
<code>RELEASE_ALL_LOCKS()</code>	Release all current named locks
<code>RELEASE_LOCK()</code>	Release the named lock

- `GET_LOCK(str, timeout)`

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. A negative `timeout` value means infinite timeout. The lock is exclusive. While held by one session, other sessions cannot obtain a lock of the same name.

Returns `1` if the lock was obtained successfully, `0` if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred (such as running out of memory or the thread was killed with `mysqladmin kill`).

A lock obtained with `GET_LOCK()` is released explicitly by executing `RELEASE_LOCK()` or implicitly when your session terminates (either normally or abnormally). Locks obtained with `GET_LOCK()` are not released when transactions commit or roll back.

`GET_LOCK()` is implemented using the metadata locking (MDL) subsystem. Multiple simultaneous locks can be acquired and `GET_LOCK()` does not release any existing locks. For example, suppose that you execute these statements:

```
SELECT GET_LOCK('lock1',10);
SELECT GET_LOCK('lock2',10);
SELECT RELEASE_LOCK('lock2');
SELECT RELEASE_LOCK('lock1');
```

The second `GET_LOCK()` acquires a second lock and both `RELEASE_LOCK()` calls return 1 (success).

It is even possible for a given session to acquire multiple locks for the same name. Other sessions cannot acquire a lock with that name until the acquiring session releases all its locks for the name.

Uniquely named locks acquired with `GET_LOCK()` appear in the Performance Schema `metadata_locks` table. The `OBJECT_TYPE` column says `USER LEVEL LOCK` and the `OBJECT_NAME` column indicates the lock name. In the case that multiple locks are acquired for the same name, only the first lock for the name registers a row in the `metadata_locks` table. Subsequent locks for the name increment a counter in the lock but do not acquire additional metadata locks. The `metadata_locks` row for the lock is deleted when the last lock instance on the name is released.

The capability of acquiring multiple locks means there is the possibility of deadlock among clients. When this happens, the server chooses a caller and terminates its lock-acquisition request with an `ER_USER_LOCK_DEADLOCK` error. This error does not cause transactions to roll back.

MySQL enforces a maximum length on lock names of 64 characters.

`GET_LOCK()` can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked within one session, `GET_LOCK()` blocks any request by another session for a lock with the same name. This enables clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also enables a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

If multiple clients are waiting for a lock, the order in which they will acquire it is undefined. Applications should not assume that clients will acquire the lock in the same order that they issued the lock requests.

`GET_LOCK()` is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

Caution

With the capability of acquiring multiple named locks, it is possible for a single statement to acquire a large number of locks. For example:

```
INSERT INTO ... SELECT GET_LOCK(t1.col_name) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure will still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent will not be satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

A different locking interface is available as either a plugin service or a set of user-defined functions. This interface provides lock namespaces and distinct read and write locks, unlike the interface

provided by `GET_LOCK()` and related functions. For details, see [Section 5.6.8.1, “The Locking Service”](#).

- `IS_FREE_LOCK(str)`

Checks whether the lock named `str` is free to use (that is, not locked). Returns `1` if the lock is free (no one is using the lock), `0` if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_USED_LOCK(str)`

Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns `NULL`.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `RELEASE_ALL_LOCKS()`

Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `RELEASE_LOCK(str)`

Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns `1` if the lock was released, `0` if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See [Section 13.2.3, “DO Statement”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

12.16 Information Functions

Table 12.20 Information Functions

Name	Description
<code>BENCHMARK()</code>	Repeatedly execute an expression
<code>CHARSET()</code>	Return the character set of the argument
<code>COERCIBILITY()</code>	Return the collation coercibility value of the string argument
<code>COLLATION()</code>	Return the collation of the string argument
<code>CONNECTION_ID()</code>	Return the connection ID (thread ID) for the connection
<code>CURRENT_ROLE()</code>	Return the current active roles
<code>CURRENT_USER()</code> , <code>CURRENT_USER</code>	The authenticated user name and host name
<code>DATABASE()</code>	Return the default (current) database name
<code>FOUND_ROWS()</code>	For a <code>SELECT</code> with a <code>LIMIT</code> clause, the number of rows that would be returned were there no <code>LIMIT</code> clause
<code>ICU_VERSION()</code>	ICU library version
<code>LAST_INSERT_ID()</code>	Value of the <code>AUTOINCREMENT</code> column for the last <code>INSERT</code>

Name	Description
<code>ROLES_GRAPHML()</code>	Return a GraphML document representing memory role subgraphs
<code>ROW_COUNT()</code>	The number of rows updated
<code>SCHEMA()</code>	Synonym for <code>DATABASE()</code>
<code>SESSION_USER()</code>	Synonym for <code>USER()</code>
<code>SYSTEM_USER()</code>	Synonym for <code>USER()</code>
<code>USER()</code>	The user name and host name provided by the client
<code>VERSION()</code>	Return a string that indicates the MySQL server version

- `BENCHMARK(count,expr)`

The `BENCHMARK()` function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MySQL processes the expression. The result value is 0, or `NULL` for inappropriate arguments such as a `NULL` or negative repeat count.

The intended use is from within the `mysql` client, which reports query execution times:

```
mysql> SELECT BENCHMARK(1000000,AES_ENCRYPT('hello','goodbye'));
+-----+
| BENCHMARK(1000000,AES_ENCRYPT('hello','goodbye')) |
+-----+
| 0 |
+-----+
1 row in set (4.74 sec)
```

The time reported is elapsed time on the client end, not CPU time on the server end. It is advisable to execute `BENCHMARK()` several times, and to interpret the result with regard to how heavily loaded the server machine is.

`BENCHMARK()` is intended for measuring the runtime performance of scalar expressions, which has some significant implications for the way that you use it and interpret the results:

- Only scalar expressions can be used. Although the expression can be a subquery, it must return a single column and at most a single row. For example, `BENCHMARK(10, (SELECT * FROM t))` will fail if the table `t` has more than one column or more than one row.
- Executing a `SELECT expr` statement `N` times differs from executing `SELECT BENCHMARK(N, expr)` in terms of the amount of overhead involved. The two have very different execution profiles and you should not expect them to take the same amount of time. The former involves the parser, optimizer, table locking, and runtime evaluation `N` times each. The latter involves only runtime evaluation `N` times, and all the other components just once. Memory structures already allocated are reused, and runtime optimizations such as local caching of results already evaluated for aggregate functions can alter the results. Use of `BENCHMARK()` thus measures performance of the runtime component by giving more weight to that component and removing the “noise” introduced by the network, parser, optimizer, and so forth.
- `CHARSET(str)`

Returns the character set of the string argument.

```
mysql> SELECT CHARSET('abc');
-> 'utf8'
mysql> SELECT CHARSET(CONVERT('abc' USING latin1));
-> 'latin1'
mysql> SELECT CHARSET(USER());
-> 'utf8'
```

- `COERCIBILITY(str)`

Returns the collation coercibility value of the string argument.

```
mysql> SELECT COERCIBILITY('abc' COLLATE utf8_swedish_ci);
-> 0
mysql> SELECT COERCIBILITY(USER());
-> 3
mysql> SELECT COERCIBILITY('abc');
-> 4
mysql> SELECT COERCIBILITY(1000);
-> 5
```

The return values have the meanings shown in the following table. Lower values have higher precedence.

Coercibility	Meaning	Example
0	Explicit collation	Value with <code>COLLATE</code> clause
1	No collation	Concatenation of strings with different collations
2	Implicit collation	Column value, stored routine parameter or local variable
3	System constant	<code>USER()</code> return value
4	Coercible	Literal string
5	Numeric	Numeric or temporal value
5	Ignorable	<code>NULL</code> or an expression derived from <code>NULL</code>

For more information, see [Section 10.8.4, “Collation Coercibility in Expressions”](#).

- `COLLATION(str)`

Returns the collation of the string argument.

```
mysql> SELECT COLLATION('abc');
-> 'utf8_general_ci'
mysql> SELECT COLLATION(_utf8mb4'abc');
-> 'utf8mb4_0900_ai_ci'
mysql> SELECT COLLATION(_latin1'abc');
-> 'latin1_swedish_ci'
```

- `CONNECTION_ID()`

Returns the connection ID (thread ID) for the connection. Every connection has an ID that is unique among the set of currently connected clients.

The value returned by `CONNECTION_ID()` is the same type of value as displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table.

```
mysql> SELECT CONNECTION_ID();
-> 23786
```

Warning

Changing the session value of the `pseudo_thread_id` system variable changes the value returned by the `CONNECTION_ID()` function.

- `CURRENT_ROLE()`

Returns a `utf8` string containing the current active roles for the current session, separated by commas, or `NONE` if there are none. The value reflects the setting of the `sql_quote_show_create` system variable.

Suppose that an account is granted roles as follows:

```
GRANT 'r1', 'r2' TO 'u1'@'localhost';
SET DEFAULT ROLE ALL TO 'u1'@'localhost';
```

In sessions for `u1`, the initial `CURRENT_ROLE()` value names the default account roles. Using `SET ROLE` changes that:

```
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `r1`@`%`,`r2`@`%` |
+-----+
mysql> SET ROLE 'r1'; SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `r1`@`%` |
+-----+
```

- `CURRENT_USER`, `CURRENT_USER()`

Returns the user name and host name combination for the MySQL account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the `utf8` character set.

The value of `CURRENT_USER()` can differ from the value of `USER()`.

```
mysql> SELECT USER();
-> 'davida@localhost'
mysql> SELECT * FROM mysql.user;
ERROR 1044: Access denied for user ''@'localhost' to
database 'mysql'
mysql> SELECT CURRENT_USER();
-> '@localhost'
```

The example illustrates that although the client specified a user name of `davida` (as indicated by the value of the `USER()` function), the server authenticated the client using an anonymous user account

(as seen by the empty user name part of the `CURRENT_USER()` value). One way this might occur is that there is no account listed in the grant tables for `davida`.

Within a stored program or view, `CURRENT_USER()` returns the account for the user who defined the object (as given by its `DEFINER` value) unless defined with the `SQL SECURITY INVOKER` characteristic. In the latter case, `CURRENT_USER()` returns the object's invoker.

Triggers and events have no option to define the `SQL SECURITY` characteristic, so for these objects, `CURRENT_USER()` returns the account for the user who defined the object. To return the invoker, use `USER()` or `SESSION_USER()`.

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, a host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

For information about the implications that this expansion of `CURRENT_USER()` has for replication, see [Section 17.5.1.8, “Replication of `CURRENT_USER\(\)`”](#).

- `DATABASE()`

Returns the default (current) database name as a string in the `utf8` character set. If there is no default database, `DATABASE()` returns `NULL`. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

```
mysql> SELECT DATABASE();
-> 'test'
```

If there is no default database, `DATABASE()` returns `NULL`.

- `FOUND_ROWS()`

Note

The `SQL_CALC_FOUND_ROWS` query modifier and accompanying `FOUND_ROWS()` function are deprecated as of MySQL 8.0.17 and will be removed in a future MySQL version. As a replacement, considering executing your query with `LIMIT`, and then a second query with `COUNT(*)` and without

`LIMIT` to determine whether there are additional rows. For example, instead of these queries:

```
SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;  
SELECT FOUND_ROWS();
```

Use these queries instead:

```
SELECT * FROM tbl_name WHERE id > 100 LIMIT 10;  
SELECT COUNT(*) FROM tbl_name WHERE id > 100;
```

`COUNT(*)` is subject to certain optimizations. `SQL_CALC_FOUND_ROWS` causes some optimizations to be disabled.

A `SELECT` statement may include a `LIMIT` clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the `LIMIT`, but without running the statement again. To obtain this row count, include an `SQL_CALC_FOUND_ROWS` option in the `SELECT` statement, and then invoke `FOUND_ROWS()` afterward:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name  
-> WHERE id > 100 LIMIT 10;  
mysql> SELECT FOUND_ROWS();
```

The second `SELECT` returns a number indicating how many rows the first `SELECT` would have returned had it been written without the `LIMIT` clause.

In the absence of the `SQL_CALC_FOUND_ROWS` option in the most recent successful `SELECT` statement, `FOUND_ROWS()` returns the number of rows in the result set returned by that statement. If the statement includes a `LIMIT` clause, `FOUND_ROWS()` returns the number of rows up to the limit. For example, `FOUND_ROWS()` returns 10 or 60, respectively, if the statement includes `LIMIT 10` or `LIMIT 50, 10`.

The row count available through `FOUND_ROWS()` is transient and not intended to be available past the statement following the `SELECT SQL_CALC_FOUND_ROWS` statement. If you need to refer to the value later, save it:

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;  
mysql> SET @rows = FOUND_ROWS();
```

If you are using `SELECT SQL_CALC_FOUND_ROWS`, MySQL must calculate how many rows are in the full result set. However, this is faster than running the query again without `LIMIT`, because the result set need not be sent to the client.

`SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` can be useful in situations when you want to restrict the number of rows that a query returns, but also determine the number of rows in the full result set without running the query again. An example is a Web script that presents a paged display

containing links to the pages that show other sections of a search result. Using `FOUND_ROWS()` enables you to determine how many other pages are needed for the rest of the result.

The use of `SQL_CALC_FOUND_ROWS` and `FOUND_ROWS()` is more complex for `UNION` statements than for simple `SELECT` statements, because `LIMIT` may occur at multiple places in a `UNION`. It may be applied to individual `SELECT` statements in the `UNION`, or global to the `UNION` result as a whole.

The intent of `SQL_CALC_FOUND_ROWS` for `UNION` is that it should return the row count that would be returned without a global `LIMIT`. The conditions for use of `SQL_CALC_FOUND_ROWS` with `UNION` are:

- The `SQL_CALC_FOUND_ROWS` keyword must appear in the first `SELECT` of the `UNION`.
- The value of `FOUND_ROWS()` is exact only if `UNION ALL` is used. If `UNION` without `ALL` is used, duplicate removal occurs and the value of `FOUND_ROWS()` is only approximate.
- If no `LIMIT` is present in the `UNION`, `SQL_CALC_FOUND_ROWS` is ignored and returns the number of rows in the temporary table that is created to process the `UNION`.

Beyond the cases described here, the behavior of `FOUND_ROWS()` is undefined (for example, its value following a `SELECT` statement that fails with an error).

Important

`FOUND_ROWS()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `ICU_VERSION()`

The version of the International Components for Unicode (ICU) library used to support regular expression operations (see [Section 12.8.2, “Regular Expressions”](#)). This function is primarily intended for use in test cases.

- `LAST_INSERT_ID()`, `LAST_INSERT_ID(expr)`

With no argument, `LAST_INSERT_ID()` returns a `BIGINT UNSIGNED` (64-bit) value representing the first automatically generated value successfully inserted for an `AUTO_INCREMENT` column as a result of the most recently executed `INSERT` statement. The value of `LAST_INSERT_ID()` remains unchanged if no rows are successfully inserted.

With an argument, `LAST_INSERT_ID()` returns an unsigned integer.

For example, after inserting a row that generates an `AUTO_INCREMENT` value, you can get the value like this:

```
mysql> SELECT LAST_INSERT_ID();
-> 195
```

The currently executing statement does not affect the value of `LAST_INSERT_ID()`. Suppose that you generate an `AUTO_INCREMENT` value with one statement, and then refer to `LAST_INSERT_ID()` in a multiple-row `INSERT` statement that inserts rows into a table with its own `AUTO_INCREMENT` column. The value of `LAST_INSERT_ID()` will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to `LAST_INSERT_ID()` and `LAST_INSERT_ID(expr)`, the effect is undefined.)

If the previous statement returned an error, the value of `LAST_INSERT_ID()` is undefined. For transactional tables, if the statement is rolled back due to an error, the value of `LAST_INSERT_ID()`

is left undefined. For manual `ROLLBACK`, the value of `LAST_INSERT_ID()` is not restored to that before the transaction; it remains as it was at the point of the `ROLLBACK`.

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

The ID that was generated is maintained in the server on a *per-connection basis*. This means that the value returned by the function to a given client is the first `AUTO_INCREMENT` value generated for most recent statement affecting an `AUTO_INCREMENT` column *by that client*. This value cannot be affected by other clients, even if they generate `AUTO_INCREMENT` values of their own. This behavior ensures that each client can retrieve its own ID without concern for the activity of other clients, and without the need for locks or transactions.

The value of `LAST_INSERT_ID()` is not changed if you set the `AUTO_INCREMENT` column of a row to a non-“magic” value (that is, a value that is not `NULL` and not `0`).

Important

If you insert multiple rows using a single `INSERT` statement, `LAST_INSERT_ID()` returns the value generated for the *first* inserted row *only*. The reason for this is to make it possible to reproduce easily the same `INSERT` statement against some other server.

For example:

```
mysql> USE test;

mysql> CREATE TABLE t (
    id INT AUTO_INCREMENT NOT NULL PRIMARY KEY,
    name VARCHAR(10) NOT NULL
);

mysql> INSERT INTO t VALUES (NULL, 'Bob');

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
+----+-----+

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+

mysql> INSERT INTO t VALUES
    (NULL, 'Mary'), (NULL, 'Jane'), (NULL, 'Lisa');

mysql> SELECT * FROM t;
+----+-----+
| id | name |
+----+-----+
|  1 | Bob  |
|  2 | Mary |
|  3 | Jane |
+----+-----+
```

```
| 4 | Lisa |
+-----+
mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 2 |
+-----+
```

Although the second `INSERT` statement inserted three new rows into `t`, the ID generated for the first of these rows was `2`, and it is this value that is returned by `LAST_INSERT_ID()` for the following `SELECT` statement.

If you use `INSERT IGNORE` and the row is ignored, the `LAST_INSERT_ID()` remains unchanged from the current value (or `0` is returned if the connection has not yet performed a successful `INSERT`) and, for non-transactional tables, the `AUTO_INCREMENT` counter is not incremented. For `InnoDB` tables, the `AUTO_INCREMENT` counter is incremented if `innodb_autoinc_lock_mode` is set to `1` or `2`, as demonstrated in the following example:

```
mysql> USE test;

mysql> SELECT @@innodb_autoinc_lock_mode;
+-----+
| @@innodb_autoinc_lock_mode |
+-----+
| 1 |
+-----+

mysql> CREATE TABLE `t` (
  `id` INT(11) NOT NULL AUTO_INCREMENT,
  `val` INT(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

# Insert two rows

mysql> INSERT INTO t (val) VALUES (1),(2);

# With auto_increment_offset=1, the inserted rows
# result in an AUTO_INCREMENT value of 3

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=latin1

# LAST_INSERT_ID() returns the first automatically generated
# value that is successfully inserted for the AUTO_INCREMENT column

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
| 1 |
+-----+

# The attempted insertion of duplicate rows fail but errors are ignored

mysql> INSERT IGNORE INTO t (val) VALUES (1),(2);
Query OK, 0 rows affected (0.00 sec)
Records: 2  Duplicates: 2  Warnings: 0

# With innodb_autoinc_lock_mode=1, the AUTO_INCREMENT counter
```

```
# is incremented for the ignored rows

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `val` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `i1` (`val`)
) ENGINE=InnoDB AUTO_INCREMENT=5 DEFAULT CHARSET=latin1

# The LAST_INSERT_ID is unchanged because the previous insert was unsuccessful

mysql> SELECT LAST_INSERT_ID();
+-----+
| LAST_INSERT_ID() |
+-----+
|                1 |
+-----+
```

For more information, see [Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”](#).

If *expr* is given as an argument to `LAST_INSERT_ID()`, the value of the argument is returned by the function and is remembered as the next value to be returned by `LAST_INSERT_ID()`. This can be used to simulate sequences:

1. Create a table to hold the sequence counter and initialize it:

```
mysql> CREATE TABLE sequence (id INT NOT NULL);
mysql> INSERT INTO sequence VALUES (0);
```

2. Use the table to generate sequence numbers like this:

```
mysql> UPDATE sequence SET id=LAST_INSERT_ID(id+1);
mysql> SELECT LAST_INSERT_ID();
```

The `UPDATE` statement increments the sequence counter and causes the next call to `LAST_INSERT_ID()` to return the updated value. The `SELECT` statement retrieves that value. The `mysql_insert_id()` C API function can also be used to get the value. See [mysql_insert_id\(\)](#).

You can generate sequences without calling `LAST_INSERT_ID()`, but the utility of using the function this way is that the ID value is maintained in the server as the last automatically generated value. It is multi-user safe because multiple clients can issue the `UPDATE` statement and get their own sequence value with the `SELECT` statement (or `mysql_insert_id()`), without affecting or being affected by other clients that generate their own sequence values.

Note that `mysql_insert_id()` is only updated after `INSERT` and `UPDATE` statements, so you cannot use the C API function to retrieve the value for `LAST_INSERT_ID(expr)` after executing other SQL statements like `SELECT` or `SET`.

- `ROLES_GRAPHML()`

Returns a `utf8` string containing a GraphML document representing memory role subgraphs. The `ROLE_ADMIN` privilege (or the deprecated `SUPER` privilege) is required to see content in the `<graphml>` element. Otherwise, the result shows only an empty element:

```
mysql> SELECT ROLES_GRAPHML();
+-----+
| ROLES_GRAPHML() |
+-----+
| <?xml version="1.0" encoding="UTF-8"?><graphml /> |
+-----+
```

- `ROW_COUNT()`

`ROW_COUNT()` returns a value as follows:

- DDL statements: 0. This applies to statements such as `CREATE TABLE` or `DROP TABLE`.
- DML statements other than `SELECT`: The number of affected rows. This applies to statements such as `UPDATE`, `INSERT`, or `DELETE` (as before), but now also to statements such as `ALTER TABLE` and `LOAD DATA`.
- `SELECT`: -1 if the statement returns a result set, or the number of rows “affected” if it does not. For example, for `SELECT * FROM t1`, `ROW_COUNT()` returns -1. For `SELECT * FROM t1 INTO OUTFILE 'file_name'`, `ROW_COUNT()` returns the number of rows written to the file.
- `SIGNAL` statements: 0.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

The `ROW_COUNT()` value is similar to the value from the `mysql_affected_rows()` C API function and the row count that the `mysql` client displays following statement execution.

```
mysql> INSERT INTO t VALUES(1),(2),(3);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|          3 |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t WHERE i IN(1,2);
Query OK, 2 rows affected (0.00 sec)

mysql> SELECT ROW_COUNT();
+-----+
| ROW_COUNT() |
+-----+
|          2 |
+-----+
1 row in set (0.00 sec)
```

Important

`ROW_COUNT()` is not replicated reliably using statement-based replication. This function is automatically replicated using row-based replication.

- `SCHEMA()`

This function is a synonym for `DATABASE()`.

- `SESSION_USER()`

`SESSION_USER()` is a synonym for `USER()`.

- `SYSTEM_USER()`

`SYSTEM_USER()` is a synonym for `USER()`.

Note

The `SYSTEM_USER()` function is distinct from the `SYSTEM_USER` privilege. The former returns the current MySQL account name. The latter distinguishes the system user and regular user account categories (see [Section 6.2.11, “Account Categories”](#)).

- `USER()`

Returns the current MySQL user name and host name as a string in the `utf8` character set.

```
mysql> SELECT USER();
-> 'david@localhost'
```

The value indicates the user name you specified when connecting to the server, and the client host from which you connected. The value can be different from that of `CURRENT_USER()`.

- `VERSION()`

Returns a string that indicates the MySQL server version. The string uses the `utf8` character set. The value might have a suffix in addition to the version number. See the description of the `version` system variable in [Section 5.1.8, “Server System Variables”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

```
mysql> SELECT VERSION();
-> '8.0.23-standard'
```

12.17 Spatial Analysis Functions

MySQL provides functions to perform various operations on spatial data. These functions can be grouped into several major categories according to the type of operation they perform:

- Functions that create geometries in various formats (WKT, WKB, internal)
- Functions that convert geometries between formats
- Functions that access qualitative or quantitative properties of a geometry
- Functions that describe relations between two geometries
- Functions that create new geometries from existing ones

For general background about MySQL support for using spatial data, see [Section 11.4, “Spatial Data Types”](#).

12.17.1 Spatial Function Reference

The following table lists each spatial function and provides a short description of each one.

Table 12.21 Spatial Functions

Name	Description
<code>GeomCollection()</code>	Construct geometry collection from geometries
<code>GeometryCollection()</code>	Construct geometry collection from geometries

Name	Description
<code>LineString()</code>	Construct <code>LineString</code> from <code>Point</code> values
<code>MBRContains()</code>	Whether MBR of one geometry contains MBR of another
<code>MBRCoveredBy()</code>	Whether one MBR is covered by another
<code>MBRCovers()</code>	Whether one MBR covers another
<code>MBRDisjoint()</code>	Whether MBRs of two geometries are disjoint
<code>MBREquals()</code>	Whether MBRs of two geometries are equal
<code>MBRIntersects()</code>	Whether MBRs of two geometries intersect
<code>MBROverlaps()</code>	Whether MBRs of two geometries overlap
<code>MBRTouches()</code>	Whether MBRs of two geometries touch
<code>MBRWithin()</code>	Whether MBR of one geometry is within MBR of another
<code>MultiLineString()</code>	Construct <code>MultiLineString</code> from <code>LineString</code> values
<code>MultiPoint()</code>	Construct <code>MultiPoint</code> from <code>Point</code> values
<code>MultiPolygon()</code>	Construct <code>MultiPolygon</code> from <code>Polygon</code> values
<code>Point()</code>	Construct <code>Point</code> from coordinates
<code>Polygon()</code>	Construct <code>Polygon</code> from <code>LineString</code> arguments
<code>ST_Area()</code>	Return <code>Polygon</code> or <code>MultiPolygon</code> area
<code>ST_AsBinary()</code> , <code>ST_AsWKB()</code>	Convert from internal geometry format to WKB
<code>ST_AsGeoJSON()</code>	Generate GeoJSON object from geometry
<code>ST_AsText()</code> , <code>ST_AsWKT()</code>	Convert from internal geometry format to WKT
<code>ST_Buffer()</code>	Return geometry of points within given distance from geometry
<code>ST_Buffer_Strategy()</code>	Produce strategy option for <code>ST_Buffer()</code>
<code>ST_Centroid()</code>	Return centroid as a point
<code>ST_Contains()</code>	Whether one geometry contains another
<code>ST_ConvexHull()</code>	Return convex hull of geometry
<code>ST_Crosses()</code>	Whether one geometry crosses another
<code>ST_Difference()</code>	Return point set difference of two geometries
<code>ST_Dimension()</code>	Dimension of geometry
<code>ST_Disjoint()</code>	Whether one geometry is disjoint from another
<code>ST_Distance()</code>	The distance of one geometry from another
<code>ST_Distance_Sphere()</code>	Minimum distance on earth between two geometries
<code>ST_EndPoint()</code>	End Point of <code>LineString</code>
<code>ST_Envelope()</code>	Return MBR of geometry
<code>ST_Equals()</code>	Whether one geometry is equal to another
<code>ST_ExteriorRing()</code>	Return exterior ring of <code>Polygon</code>
<code>ST_GeoHash()</code>	Produce a geohash value
<code>ST_GeomCollFromText()</code> , <code>ST_GeometryCollectionFromText()</code> , <code>ST_GeomCollFromTxt()</code>	Return geometry collection from WKT
<code>ST_GeomCollFromWKB()</code> , <code>ST_GeometryCollectionFromWKB()</code>	Return geometry collection from WKB
<code>ST_GeometryN()</code>	Return N-th geometry from geometry collection

Name	Description
<code>ST_GeometryType()</code>	Return name of geometry type
<code>ST_GeomFromGeoJSON()</code>	Generate geometry from GeoJSON object
<code>ST_GeomFromText()</code> , <code>ST_GeometryFromText()</code>	Return geometry from WKT
<code>ST_GeomFromWKB()</code> , <code>ST_GeometryFromWKB()</code>	Return geometry from WKB
<code>ST_InteriorRingN()</code>	Return N-th interior ring of Polygon
<code>ST_Intersection()</code>	Return point set intersection of two geometries
<code>ST_Intersects()</code>	Whether one geometry intersects another
<code>ST_IsClosed()</code>	Whether a geometry is closed and simple
<code>ST_IsEmpty()</code>	Whether a geometry is empty
<code>ST_IsSimple()</code>	Whether a geometry is simple
<code>ST_IsValid()</code>	Whether a geometry is valid
<code>ST_LatFromGeoHash()</code>	Return latitude from geohash value
<code>ST_Latitude()</code> (introduced 8.0.12)	Return latitude of Point
<code>ST_Length()</code>	Return length of LineString
<code>ST_LineFromText()</code> , <code>ST_LineStringFromText()</code>	Construct LineString from WKT
<code>ST_LineFromWKB()</code> , <code>ST_LineStringFromWKB()</code>	Construct LineString from WKB
<code>ST_LongFromGeoHash()</code>	Return longitude from geohash value
<code>ST_Longitude()</code> (introduced 8.0.12)	Return longitude of Point
<code>ST_MakeEnvelope()</code>	Rectangle around two points
<code>ST_MLineFromText()</code> , <code>ST_MultiLineStringFromText()</code>	Construct MultiLineString from WKT
<code>ST_MLineFromWKB()</code> , <code>ST_MultiLineStringFromWKB()</code>	Construct MultiLineString from WKB
<code>ST_MPointFromText()</code> , <code>ST_MultiPointFromText()</code>	Construct MultiPoint from WKT
<code>ST_MPointFromWKB()</code> , <code>ST_MultiPointFromWKB()</code>	Construct MultiPoint from WKB
<code>ST_MPolyFromText()</code> , <code>ST_MultiPolygonFromText()</code>	Construct MultiPolygon from WKT
<code>ST_MPolyFromWKB()</code> , <code>ST_MultiPolygonFromWKB()</code>	Construct MultiPolygon from WKB
<code>ST_NumGeometries()</code>	Return number of geometries in geometry collection
<code>ST_NumInteriorRing()</code> , <code>ST_NumInteriorRings()</code>	Return number of interior rings in Polygon
<code>ST_NumPoints()</code>	Return number of points in LineString
<code>ST_Overlaps()</code>	Whether one geometry overlaps another
<code>ST_PointFromGeoHash()</code>	Convert geohash value to POINT value
<code>ST_PointFromText()</code>	Construct Point from WKT
<code>ST_PointFromWKB()</code>	Construct Point from WKB
<code>ST_PointN()</code>	Return N-th point from LineString

Name	Description
<code>ST_PolyFromText()</code> , <code>ST_PolygonFromText()</code>	Construct Polygon from WKT
<code>ST_PolyFromWKB()</code> , <code>ST_PolygonFromWKB()</code>	Construct Polygon from WKB
<code>ST_Simplify()</code>	Return simplified geometry
<code>ST_SRID()</code>	Return spatial reference system ID for geometry
<code>ST_StartPoint()</code>	Start Point of LineString
<code>ST_SwapXY()</code>	Return argument with X/Y coordinates swapped
<code>ST_SymDifference()</code>	Return point set symmetric difference of two geometries
<code>ST_Touches()</code>	Whether one geometry touches another
<code>ST_Transform()</code> (introduced 8.0.13)	Transform coordinates of geometry
<code>ST_Union()</code>	Return point set union of two geometries
<code>ST_Validate()</code>	Return validated geometry
<code>ST_Within()</code>	Whether one geometry is within another
<code>ST_X()</code>	Return X coordinate of Point
<code>ST_Y()</code>	Return Y coordinate of Point

12.17.2 Argument Handling by Spatial Functions

Spatial values, or geometries, have the properties described in [Section 11.4.2.2, “Geometry Class”](#). The following discussion lists general spatial function argument-handling characteristics. Specific functions or groups of functions may have additional or different argument-handling characteristics, as discussed in the sections where those function descriptions occur. Where that is true, those descriptions take precedence over the general discussion here.

Spatial functions are defined only for valid geometry values. See [Section 11.4.4, “Geometry Well-Formedness and Validity”](#).

Each geometry value is associated with a spatial reference system (SRS), which is a coordinate-based system for geographic locations. See [Section 11.4.5, “Spatial Reference System Support”](#)

The spatial reference identifier (SRID) of a geometry identifies the SRS in which the geometry is defined. In MySQL, the SRID value is an integer associated with the geometry value. The maximum usable SRID value is $2^{32}-1$. If a larger value is given, only the lower 32 bits are used.

SRID 0 represents an infinite flat Cartesian plane with no units assigned to its axes. To ensure SRID 0 behavior, create geometry values using SRID 0. SRID 0 is the default for new geometry values if no SRID is specified.

For computations on multiple geometry values, all values must be in the same SRS or an error occurs. Thus, spatial functions that take multiple geometry arguments require those arguments to have the same SRID value. If a spatial function returns `ER_GIS_DIFFERENT_SRIDS`, it means that the geometry arguments did not all have the same SRID. You must modify them to have the same SRID.

A geometry returned by a spatial function is in the SRS of the geometry arguments because geometry values produced by any spatial function inherit the SRID of the geometry arguments.

The [Open Geospatial Consortium](#) guidelines require that input polygons already be closed, so unclosed polygons are rejected as invalid rather than being closed.

In MySQL, the only valid empty geometry is represented in the form of an empty geometry collection. Empty geometry collection handling is as follows: An empty WKT input geometry collection may be specified as `'GEOMETRYCOLLECTION()'`. This is also the output WKT resulting from a spatial operation that produces an empty geometry collection.

During parsing of a nested geometry collection, the collection is flattened and its basic components are used in various GIS operations to compute results. This provides additional flexibility to users because it is unnecessary to be concerned about the uniqueness of geometry data. Nested geometry collections may be produced from nested GIS function calls without having to be explicitly flattened first.

12.17.3 Functions That Create Geometry Values from WKT Values

These functions take as arguments a Well-Known Text (WKT) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKT format, see [Well-Known Text \(WKT\) Format](#).

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSS), and return results appropriate to the SRS.

`ST_GeomFromText()` accepts a WKT value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Functions such as `ST_MPointFromText()` and `ST_GeomFromText()` that accept WKT-format representations of `MultiPoint` values permit individual points within values to be surrounded by parentheses. For example, both of the following function calls are valid:

```
ST_MPointFromText('MULTIPOINT (1 1, 2 2, 3 3)')
ST_MPointFromText('MULTIPOINT ((1 1), (2 2), (3 3))')
```

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS `'GEOMETRYCOLLECTION EMPTY'` standard syntax and MySQL `'GEOMETRYCOLLECTION()'` nonstandard syntax. Functions such as `ST_AsWKT()` that produce WKT values produce `'GEOMETRYCOLLECTION EMPTY'` standard syntax:

```
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+-----+-----+
| ST_AsWKT(@s1) | ST_AsWKT(@s2) |
+-----+-----+
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+-----+-----+
```

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any geometry argument is `NULL` or is not a syntactically well-formed geometry, or if the SRID argument is `NULL`, the return value is `NULL`.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude value is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If a latitude value is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKT values:

- `ST_GeomCollFromText(wkt[, srid[, options]])`,
`ST_GeometryCollectionFromText(wkt[, srid[, options]])`,
`ST_GeomCollFromText(wkt[, srid[, options]])`

Constructs a `GeometryCollection` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

```
mysql> SET @g = "MULTILINESTRING((10 10, 11 11), (9 9, 10 10));"
mysql> SELECT ST_AsText(ST_GeomCollFromText(@g));
+-----+
| ST_AsText(ST_GeomCollFromText(@g)) |
+-----+
| MULTILINESTRING((10 10,11 11),(9 9,10 10)) |
+-----+
```

- `ST_GeomFromText(wkt[, srid[, options]])`, `ST_GeometryFromText(wkt[, srid[, options]])`

Constructs a geometry value of any type using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromText(wkt[, srid[, options]])`, `ST_LineStringFromText(wkt[, srid[, options]])`

Constructs a `LineString` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromText(wkt[, srid[, options]])`, `ST_MultiLineStringFromText(wkt[, srid[, options]])`

Constructs a `MultiLineString` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromText(wkt[, srid[, options]])`, `ST_MultiPointFromText(wkt[, srid[, options]])`

Constructs a `MultiPoint` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromText(wkt[, srid[, options]])`, `ST_MultiPolygonFromText(wkt[, srid[, options]])`

Constructs a `MultiPolygon` value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_PointFromText(wkt[, srid[, options]])`

Constructs a `Point` value using its WKT representation and SRID.

`ST_PointFromText()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromText(wkt[, srid[, options]])`, `ST_PolygonFromText(wkt[, srid[, options]])`

Constructs a [Polygon](#) value using its WKT representation and SRID.

These functions handle their arguments as described in the introduction to this section.

12.17.4 Functions That Create Geometry Values from WKB Values

These functions take as arguments a [BLOB](#) containing a Well-Known Binary (WKB) representation and, optionally, a spatial reference system identifier (SRID). They return the corresponding geometry. For a description of WKB format, see [Well-Known Binary \(WKB\) Format](#).

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

[ST_GeomFromWKB\(\)](#) accepts a WKB value of any geometry type as its first argument. Other functions provide type-specific construction functions for construction of geometry values of each geometry type.

Prior to MySQL 8.0, these functions also accepted geometry objects as returned by the functions in [Section 12.17.5, “MySQL-Specific Functions That Create Geometry Values”](#). Geometry arguments are no longer permitted and produce an error. To migrate calls from using geometry arguments to using WKB arguments, follow these guidelines:

- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0))` as `Point(0, 0)`.
- Rewrite constructs such as `ST_GeomFromWKB(Point(0, 0), 4326)` as `ST_SRID(Point(0, 0), 4326)` or `ST_GeomFromWKB(ST_AsWKB(Point(0, 0)), 4326)`.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If the WKB or SRID argument is `NULL`, the return value is `NULL`.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- If an SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude value is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If a latitude value is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

These functions are available for creating geometries from WKB values:

- `ST_GeomCollFromWKB(wkb[, srid[, options]])`,
`ST_GeometryCollectionFromWKB(wkb[, srid[, options]])`

Constructs a [GeometryCollection](#) value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_GeomFromWKB(wkb[, srid[, options]]), ST_GeometryFromWKB(wkb[, srid[, options]])`

Constructs a geometry value of any type using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_LineFromWKB(wkb[, srid[, options]]), ST_LineStringFromWKB(wkb[, srid[, options]])`

Constructs a `LineString` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MLineFromWKB(wkb[, srid[, options]]), ST_MultiLineStringFromWKB(wkb[, srid[, options]])`

Constructs a `MultiLineString` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPointFromWKB(wkb[, srid[, options]]), ST_MultiPointFromWKB(wkb[, srid[, options]])`

Constructs a `MultiPoint` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_MPolyFromWKB(wkb[, srid[, options]]), ST_MultiPolygonFromWKB(wkb[, srid[, options]])`

Constructs a `MultiPolygon` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

- `ST_PointFromWKB(wkb[, srid[, options]])`

Constructs a `Point` value using its WKB representation and SRID.

`ST_PointFromWKB()` handles its arguments as described in the introduction to this section.

- `ST_PolyFromWKB(wkb[, srid[, options]]), ST_PolygonFromWKB(wkb[, srid[, options]])`

Constructs a `Polygon` value using its WKB representation and SRID.

These functions handle their arguments as described in the introduction to this section.

12.17.5 MySQL-Specific Functions That Create Geometry Values

MySQL provides a set of useful nonstandard functions for creating geometry values. The functions described in this section are MySQL extensions to the OpenGIS specification.

These functions produce geometry objects from either WKB values or geometry objects as arguments. If any argument is not a proper WKB or geometry representation of the proper object type, the return value is `NULL`.

For example, you can insert the geometry return value from `Point()` directly into a `POINT` column:

```
INSERT INTO t1 (pt_col) VALUES(Point(1,2));
```

- `GeomCollection(g[, g] ...)`

Constructs a `GeomCollection` value from the geometry arguments.

`GeomCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

`GeomCollection()` with no arguments is permitted as a way to create an empty geometry. Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

`GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- `GeometryCollection(g [, g] ...)`

Constructs a `GeomCollection` value from the geometry arguments.

`GeometryCollection()` returns all the proper geometries contained in the arguments even if a nonsupported geometry is present.

`GeometryCollection()` with no arguments is permitted as a way to create an empty geometry. Also, functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS 'GEOMETRYCOLLECTION EMPTY' standard syntax and MySQL 'GEOMETRYCOLLECTION()' nonstandard syntax.

`GeomCollection()` and `GeometryCollection()` are synonymous, with `GeomCollection()` the preferred function.

- `LineString(pt [, pt] ...)`

Constructs a `LineString` value from a number of `Point` or WKB `Point` arguments. If the number of arguments is less than two, the return value is `NULL`.

- `MultiLineString(ls [, ls] ...)`

Constructs a `MultiLineString` value using `LineString` or WKB `LineString` arguments.

- `MultiPoint(pt [, pt2] ...)`

Constructs a `MultiPoint` value using `Point` or WKB `Point` arguments.

- `MultiPolygon(poly [, poly] ...)`

Constructs a `MultiPolygon` value from a set of `Polygon` or WKB `Polygon` arguments.

- `Point(x, y)`

Constructs a `Point` using its coordinates.

- `Polygon(ls [, ls] ...)`

Constructs a `Polygon` value from a number of `LineString` or WKB `LineString` arguments. If any argument does not represent a `LinearRing` (that is, not a closed and simple `LineString`), the return value is `NULL`.

12.17.6 Geometry Format Conversion Functions

MySQL supports the functions listed in this section for converting geometry values from internal geometry format to WKT or WKB format, or for swapping the order of X and Y coordinates.

There are also functions to convert a string from WKT or WKB format to internal geometry format. See [Section 12.17.3, “Functions That Create Geometry Values from WKT Values”](#), and [Section 12.17.4, “Functions That Create Geometry Values from WKB Values”](#).

Functions such as `ST_GeomFromText()` that accept WKT geometry collection arguments understand both OpenGIS `'GEOMETRYCOLLECTION EMPTY'` standard syntax and MySQL `'GEOMETRYCOLLECTION()'` nonstandard syntax. Another way to produce an empty geometry collection is by calling `GeometryCollection()` with no arguments. Functions such as `ST_AsWKT()` that produce WKT values produce `'GEOMETRYCOLLECTION EMPTY'` standard syntax:

```
mysql> SET @s1 = ST_GeomFromText('GEOMETRYCOLLECTION()');
mysql> SET @s2 = ST_GeomFromText('GEOMETRYCOLLECTION EMPTY');
mysql> SELECT ST_AsWKT(@s1), ST_AsWKT(@s2);
+-----+-----+
| ST_AsWKT(@s1)          | ST_AsWKT(@s2)          |
+-----+-----+
| GEOMETRYCOLLECTION EMPTY | GEOMETRYCOLLECTION EMPTY |
+-----+-----+
mysql> SELECT ST_AsWKT(GeomCollection());
+-----+
| ST_AsWKT(GeomCollection()) |
+-----+
| GEOMETRYCOLLECTION EMPTY    |
+-----+
```

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is in an undefined spatial reference system, the axes are output in the order they appear in the geometry and an `ER_WARN_SRS_NOT_FOUND_AXIS_ORDER` warning occurs.
- By default, geographic coordinates (latitude, longitude) are interpreted as in the order specified by the spatial reference system of geometry arguments. An optional `options` argument may be given to override the default axis order. `options` consists of a list of comma-separated `key=value`. The only permitted `key` value is `axis-order`, with permitted values of `lat-long`, `long-lat` and `srid-defined` (the default).

If the `options` argument is `NULL`, the return value is `NULL`. If the `options` argument is invalid, an error occurs to indicate why.

- Otherwise, the return value is non-`NULL`.

These functions are available for format conversions or coordinate swapping:

- `ST_AsBinary(g [, options]), ST_AsWKB(g [, options])`

Converts a value in internal geometry format to its WKB representation and returns the binary result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional `options` argument may be given to override the default axis order.

`ST_AsBinary()` and `ST_AsWKB()` handle their arguments as described in the introduction to this section.

```
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)', 4326);
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g)));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g))) |
+-----+
| LINESTRING(5 0,10 5,15 10)              |
+-----+
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat')));
+-----+
```

```
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=long-lat'))) |
+-----+
| LINESTRING(0 5,5 10,10 15) |
+-----+
mysql> SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long')));
+-----+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@g, 'axis-order=lat-long'))) |
+-----+
| LINESTRING(5 0,10 5,15 10) |
+-----+
```

- `ST_AsText(g [, options]), ST_AsWKT(g [, options])`

Converts a value in internal geometry format to its WKT representation and returns the string result.

The function return value has geographic coordinates (latitude, longitude) in the order specified by the spatial reference system that applies to the geometry argument. An optional `options` argument may be given to override the default axis order.

`ST_AsText()` and `ST_AsWKT()` handle their arguments as described in the introduction to this section.

```
mysql> SET @g = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_GeomFromText(@g));
+-----+
| ST_AsText(ST_GeomFromText(@g)) |
+-----+
| LINESTRING(1 1,2 2,3 3) |
+-----+
```

Output for `MultiPoint` values includes parentheses around each point. For example:

```
mysql> SELECT ST_AsText(ST_GeomFromText(@mp));
+-----+
| ST_AsText(ST_GeomFromText(@mp)) |
+-----+
| MULTIPOINT((1 1),(2 2),(3 3)) |
+-----+
```

- `ST_SwapXY(g)`

Accepts an argument in internal geometry format, swaps the X and Y values of each coordinate pair within the geometry, and returns the result.

`ST_SwapXY()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g = ST_LineFromText('LINESTRING(0 5,5 10,10 15)');
mysql> SELECT ST_AsText(@g);
+-----+
| ST_AsText(@g) |
+-----+
| LINESTRING(0 5,5 10,10 15) |
+-----+
mysql> SELECT ST_AsText(ST_SwapXY(@g));
+-----+
| ST_AsText(ST_SwapXY(@g)) |
+-----+
| LINESTRING(5 0,10 5,15 10) |
+-----+
```

12.17.7 Geometry Property Functions

Each function that belongs to this group takes a geometry value as its argument and returns some quantitative or qualitative property of the geometry. Some functions restrict their argument type. Such functions return `NULL` if the argument is of an incorrect geometry type. For example, the `ST_Area()` polygon function returns `NULL` if the object type is neither `Polygon` nor `MultiPolygon`.

12.17.7.1 General Geometry Property Functions

The functions listed in this section do not restrict their argument and accept a geometry value of any type.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an `ER_DATA_OUT_OF_RANGE` error occurs.
- If any SRID argument refers to an undefined SRS, an `ER_SRS_NOT_FOUND` error occurs.
- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining geometry properties:

- `ST_Dimension(g)`

Returns the inherent dimension of the geometry value `g`. The dimension can be `-1`, `0`, `1`, or `2`. The meaning of these values is given in [Section 11.4.2.2, “Geometry Class”](#).

`ST_Dimension()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)'));
+-----+
| ST_Dimension(ST_GeomFromText('LineString(1 1,2 2)')) |
+-----+
| 1 |
+-----+
```

- `ST_Envelope(g)`

Returns the minimum bounding rectangle (MBR) for the geometry value `g`. The result is returned as a `Polygon` value that is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')));
+-----+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,2 2)')) |
+-----+
| POLYGON((1 1,2 1,2 2,1 2,1 1)) |
+-----+
```

If the argument is a point or a vertical or horizontal line segment, `ST_Envelope()` returns the point or the line segment as its MBR rather than returning an invalid polygon:

```
mysql> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')));
+-----+
| ST_AsText(ST_Envelope(ST_GeomFromText('LineString(1 1,1 2)')) |
+-----+
| LINESTRING(1 1,1 2) |
+-----+
```

`ST_Envelope()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

- `ST_GeometryType(g)`

Returns a binary string indicating the name of the geometry type of which the geometry instance *g* is a member. The name corresponds to one of the instantiable [Geometry](#) subclasses.

`ST_GeometryType()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_GeometryType(ST_GeomFromText('POINT(1 1)'));
+-----+
| ST_GeometryType(ST_GeomFromText('POINT(1 1)')) |
+-----+
| POINT                                           |
+-----+
```

- `ST_IsEmpty(g)`

This function is a placeholder that returns 1 for an empty geometry collection value or 0 otherwise.

The only valid empty geometry is represented in the form of an empty geometry collection value. MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

`ST_IsEmpty()` handles its arguments as described in the introduction to this section.

- `ST_IsSimple(g)`

Returns 1 if the geometry value *g* is simple according to the ISO *SQL/MM Part 3: Spatial* standard. `ST_IsSimple()` returns 0 if the argument is not simple.

The descriptions of the instantiable geometric classes given under [Section 11.4.2, “The OpenGIS Geometry Model”](#) include the specific conditions that cause class instances to be classified as not simple.

`ST_IsSimple()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If a longitude argument is not in the range $[-180, 180]$, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (`ER_LONGITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).
 - If a latitude argument is not in the range $[-90, 90]$, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- `ST_SRID(g[, srid])`

With a single argument representing a valid geometry object *g*, `ST_SRID()` returns an integer indicating the ID of the spatial reference system (SRS) associated with *g*.

With the optional second argument representing a valid SRID value, `ST_SRID()` returns an object with the same type as its first argument with an SRID value equal to the second argument. This only sets the SRID value of the object; it does not perform any transformation of coordinate values.

`ST_SRID()` handles its arguments as described in the introduction to this section, with this exception:

- For the single-argument syntax, `ST_SRID()` returns the geometry SRID even if it refers to an undefined SRS. An `ER_SRS_NOT_FOUND` error does not occur.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- `ST_SRID()` changes the geometry SRID value without transforming its coordinates.
- `ST_Transform()` transforms the geometry coordinates in addition to changing its SRID value.

```
mysql> SET @g = ST_GeomFromText('LineString(1 1,2 2)', 0);
mysql> SELECT ST_SRID(@g);
+-----+
| ST_SRID(@g) |
+-----+
|           0 |
+-----+
mysql> SET @g = ST_SRID(@g, 4326);
mysql> SELECT ST_SRID(@g);
+-----+
| ST_SRID(@g) |
+-----+
|          4326 |
+-----+
```

It is possible to create a geometry in a particular SRID by passing to `ST_SRID()` the result of one of the MySQL-specific functions for creating spatial values, along with an SRID value. For example:

```
SET @g1 = ST_SRID(Point(1, 1), 4326);
```

However, that method creates the geometry in SRID 0, then casts it to SRID 4326 (WGS 84). A preferable alternative is to create the geometry with the correct spatial reference system to begin with. For example:

```
SET @g1 = ST_PointFromText('POINT(1 1)', 4326);
SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
```

The two-argument form of `ST_SRID()` is useful for tasks such as correcting or changing the SRS of geometries that have an incorrect SRID.

12.17.7.2 Point Property Functions

A `Point` consists of X and Y coordinates, which may be obtained using the `ST_X()` and `ST_Y()` functions, respectively. These functions also permit an optional second argument that specifies an X or Y coordinate value, in which case the function result is the `Point` object from the first argument with the appropriate coordinate modified to be equal to the second argument.

For `Point` objects that have a geographic spatial reference system (SRS), the longitude and latitude may be obtained using the `ST_Longitude()` and `ST_Latitude()` functions, respectively. These functions also permit an optional second argument that specifies a longitude or latitude value, in which case the function result is the `Point` object from the first argument with the longitude or latitude modified to be equal to the second argument.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is a valid geometry but not a `Point` object, an `ER_UNEXPECTED_GEOMETRY_TYPE` error occurs.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If an X or Y coordinate argument is provided and the value is `-inf`, `+inf`, or `NaN`, an `ER_DATA_OUT_OF_RANGE` error occurs.

- If a longitude or latitude argument is out of range, an error occurs:
 - If a longitude argument is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
 - If a latitude argument is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining point properties:

- `ST_Latitude(p [, new_latitude_val])`

With a single argument representing a valid `Point` object *p* that has a geographic spatial reference system (SRS), `ST_Latitude()` returns the latitude value of *p* as a double-precision number.

With the optional second argument representing a valid latitude value, `ST_Latitude()` returns a `Point` object like the first argument with its latitude equal to the second argument.

`ST_Latitude()` handles its arguments as described in the introduction to this section, with the addition that if the `Point` object is valid but does not have a geographic SRS, an `ER_SRS_NOT_GEOGRAPHIC` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Latitude(@pt);
+-----+
| ST_Latitude(@pt) |
+-----+
| 45 |
+-----+
mysql> SELECT ST_AsText(ST_Latitude(@pt, 10));
+-----+
| ST_AsText(ST_Latitude(@pt, 10)) |
+-----+
| POINT(10 90) |
+-----+
```

This function was added in MySQL 8.0.12.

- `ST_Longitude(p [, new_longitude_val])`

With a single argument representing a valid `Point` object *p* that has a geographic spatial reference system (SRS), `ST_Longitude()` returns the longitude value of *p* as a double-precision number.

With the optional second argument representing a valid longitude value, `ST_Longitude()` returns a `Point` object like the first argument with its longitude equal to the second argument.

`ST_Longitude()` handles its arguments as described in the introduction to this section, with the addition that if the `Point` object is valid but does not have a geographic SRS, an `ER_SRS_NOT_GEOGRAPHIC` error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(45 90)', 4326);
mysql> SELECT ST_Longitude(@pt);
+-----+
| ST_Longitude(@pt) |
+-----+
| 90 |
+-----+
mysql> SELECT ST_AsText(ST_Longitude(@pt, 10));
+-----+
| ST_AsText(ST_Longitude(@pt, 10)) |
+-----+
| POINT(45 10) |
+-----+
```

This function was added in MySQL 8.0.12.

- `ST_X(p[, new_x_val])`

With a single argument representing a valid [Point](#) object `p`, `ST_X()` returns the X-coordinate value of `p` as a double-precision number. As of MySQL 8.0.12, the X coordinate is considered to refer to the axis that appears first in the [Point](#) spatial reference system (SRS) definition.

With the optional second argument, `ST_X()` returns a [Point](#) object like the first argument with its X coordinate equal to the second argument. As of MySQL 8.0.12, if the [Point](#) object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

`ST_X()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_X(Point(56.7, 53.34));
+-----+
| ST_X(Point(56.7, 53.34)) |
+-----+
| 56.7 |
+-----+
mysql> SELECT ST_AsText(ST_X(Point(56.7, 53.34), 10.5));
+-----+
| ST_AsText(ST_X(Point(56.7, 53.34), 10.5)) |
+-----+
| POINT(10.5 53.34) |
+-----+
```

- `ST_Y(p[, new_y_val])`

With a single argument representing a valid [Point](#) object `p`, `ST_Y()` returns the Y-coordinate value of `p` as a double-precision number. As of MySQL 8.0.12, the Y coordinate is considered to refer to the axis that appears second in the [Point](#) spatial reference system (SRS) definition.

With the optional second argument, `ST_Y()` returns a [Point](#) object like the first argument with its Y coordinate equal to the second argument. As of MySQL 8.0.12, if the [Point](#) object has a geographic SRS, the second argument must be in the proper range for longitude or latitude values.

`ST_Y()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_Y(Point(56.7, 53.34));
+-----+
| ST_Y(Point(56.7, 53.34)) |
+-----+
| 53.34 |
+-----+
mysql> SELECT ST_AsText(ST_Y(Point(56.7, 53.34), 10.5));
+-----+
| ST_AsText(ST_Y(Point(56.7, 53.34), 10.5)) |
+-----+
| POINT(56.7 10.5) |
+-----+
```

12.17.7.3 LineString and MultiLineString Property Functions

A [LineString](#) consists of [Point](#) values. You can extract particular points of a [LineString](#), count the number of points that it contains, or obtain its length.

Some functions in this section also work for [MultiLineString](#) values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is [NULL](#) or any geometry argument is an empty geometry, the return value is [NULL](#).
- If any geometry argument is not a syntactically well-formed geometry, an [ER_GIS_INVALID_DATA](#) error occurs.

- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining linestring properties:

- `ST_EndPoint(ls)`

Returns the `Point` that is the endpoint of the `LineString` value *ls*.

`ST_EndPoint()` handles its arguments as described in the introduction to this section.

```
mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_EndPoint(ST_GeomFromText(@ls)));
+-----+
| ST_AsText(ST_EndPoint(ST_GeomFromText(@ls))) |
+-----+
| POINT(3 3) |
+-----+
```

- `ST_IsClosed(ls)`

For a `LineString` value *ls*, `ST_IsClosed()` returns 1 if *ls* is closed (that is, its `ST_StartPoint()` and `ST_EndPoint()` values are the same).

For a `MultiLineString` value *ls*, `ST_IsClosed()` returns 1 if *ls* is closed (that is, the `ST_StartPoint()` and `ST_EndPoint()` values are the same for each `LineString` in *ls*).

`ST_IsClosed()` returns 0 if *ls* is not closed, and `NULL` if *ls* is `NULL`.

`ST_IsClosed()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```
mysql> SET @ls1 = 'LineString(1 1,2 2,3 3,2 2)';
mysql> SET @ls2 = 'LineString(1 1,2 2,3 3,1 1)';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls1));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls1)) |
+-----+
| 0 |
+-----+

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls2));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls2)) |
+-----+
| 1 |
+-----+

mysql> SET @ls3 = 'MultiLineString((1 1,2 2,3 3),(4 4,5 5))';

mysql> SELECT ST_IsClosed(ST_GeomFromText(@ls3));
+-----+
| ST_IsClosed(ST_GeomFromText(@ls3)) |
+-----+
| 0 |
+-----+
```

- `ST_Length(ls [, unit])`

Returns a double-precision number indicating the length of the [LineString](#) or [MultiLineString](#) value *ls* in its associated spatial reference system. The length of a [MultiLineString](#) value is equal to the sum of the lengths of its elements.

[ST_Length\(\)](#) computes a result as follows:

- If the geometry is a valid [LineString](#) in a Cartesian SRS, the return value is the Cartesian length of the geometry.
- If the geometry is a valid [MultiLineString](#) in a Cartesian SRS, the return value is the sum of the Cartesian lengths of its elements.
- If the geometry is a valid [LineString](#) in a geographic SRS, the return value is the geodetic length of the geometry in that SRS, in meters.
- If the geometry is a valid [MultiLineString](#) in a geographic SRS, the return value is the sum of the geodetic lengths of its elements in that SRS, in meters.

[ST_Length\(\)](#) handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is not a [LineString](#) or [MultiLineString](#), the return value is [NULL](#).
- If the geometry is geometrically invalid, either the result is an undefined length (that is, it can be any number), or an error occurs.
- If the length computation result is `+inf`, an [ER_DATA_OUT_OF_RANGE](#) error occurs.
- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If a longitude argument is not in the range $(-180, 180]$, an [ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE](#) error occurs ([ER_LONGITUDE_OUT_OF_RANGE](#) prior to MySQL 8.0.12).
 - If a latitude argument is not in the range $[-90, 90]$, an [ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE](#) error occurs ([ER_LATITUDE_OUT_OF_RANGE](#) prior to MySQL 8.0.12).

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

As of MySQL 8.0.16, [ST_Length\(\)](#) permits an optional *unit* argument that specifies the linear unit for the returned length value. These rules apply:

- If a unit is specified but not supported by MySQL, an [ER_UNIT_NOT_FOUND](#) error occurs.
- If a supported linear unit is specified and the SRID is 0, an [ER_GEOMETRY_IN_UNKNOWN_LENGTH_UNIT](#) error occurs.
- If a supported linear unit is specified and the SRID is not 0, the result is in that unit.
- If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

A unit is supported if it is found in the [INFORMATION_SCHEMA ST_UNITS_OF_MEASURE](#) table. See [Section 25.37, “The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table”](#).

```
mysql> SET @ls = ST_GeomFromText('LineString(1 1,2 2,3 3)');
mysql> SELECT ST_Length(@ls);
+-----+
```

```

| ST_Length(@ls) |
+-----+
| 2.8284271247461903 |
+-----+

mysql> SET @mls = ST_GeomFromText('MultiLineString((1 1,2 2,3 3),(4 4,5 5))');
mysql> SELECT ST_Length(@mls);
+-----+
| ST_Length(@mls) |
+-----+
| 4.242640687119286 |
+-----+

mysql> SET @ls = ST_GeomFromText('LineString(1 1,2 2,3 3)', 4326);
mysql> SELECT ST_Length(@ls);
+-----+
| ST_Length(@ls) |
+-----+
| 313701.9623204328 |
+-----+

mysql> SELECT ST_Length(@ls, 'metre');
+-----+
| ST_Length(@ls, 'metre') |
+-----+
| 313701.9623204328 |
+-----+

mysql> SELECT ST_Length(@ls, 'foot');
+-----+
| ST_Length(@ls, 'foot') |
+-----+
| 1029205.9131247795 |
+-----+

```

- `ST_NumPoints(ls)`

Returns the number of `Point` objects in the `LineString` value `ls`.

`ST_NumPoints()` handles its arguments as described in the introduction to this section.

```

mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_NumPoints(ST_GeomFromText(@ls));
+-----+
| ST_NumPoints(ST_GeomFromText(@ls)) |
+-----+
| 3 |
+-----+

```

- `ST_PointN(ls, N)`

Returns the `N`-th `Point` in the `LineString` value `ls`. Points are numbered beginning with 1.

`ST_PointN()` handles its arguments as described in the introduction to this section.

```

mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_PointN(ST_GeomFromText(@ls), 2));
+-----+
| ST_AsText(ST_PointN(ST_GeomFromText(@ls), 2)) |
+-----+
| POINT(2 2) |
+-----+

```

- `ST_StartPoint(ls)`

Returns the `Point` that is the start point of the `LineString` value `ls`.

`ST_StartPoint()` handles its arguments as described in the introduction to this section.

```

mysql> SET @ls = 'LineString(1 1,2 2,3 3)';
mysql> SELECT ST_AsText(ST_StartPoint(ST_GeomFromText(@ls)));
+-----+

```

```

| ST_AsText(ST_StartPoint(ST_GeomFromText(@ls))) |
+-----+
| POINT(1 1) |
+-----+

```

12.17.7.4 Polygon and MultiPolygon Property Functions

Functions in this section return properties of [Polygon](#) or [MultiPolygon](#) values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is [NULL](#) or any geometry argument is an empty geometry, the return value is [NULL](#).
- If any geometry argument is not a syntactically well-formed geometry, an [ER_GIS_INVALID_DATA](#) error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an [ER_SRS_NOT_FOUND](#) error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an [ER_GIS_DIFFERENT_SRIDS](#) error occurs.
- Otherwise, the return value is non-[NULL](#).

These functions are available for obtaining polygon properties:

- [ST_Area\({poly|mpoly} \)](#)

Returns a double-precision number indicating the area of the [Polygon](#) or [MultiPolygon](#) argument, as measured in its spatial reference system.

As of MySQL 8.0.13, [ST_Area\(\)](#) handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is geometrically invalid, either the result is an undefined area (that is, it can be any number), or an error occurs.
- If the geometry is valid but is not a [Polygon](#) or [MultiPolygon](#) object, an [ER_UNEXPECTED_GEOMETRY_TYPE](#) error occurs.
- If the geometry is a valid [Polygon](#) in a Cartesian SRS, the result is the Cartesian area of the polygon.
- If the geometry is a valid [MultiPolygon](#) in a Cartesian SRS, the result is the sum of the Cartesian area of the polygons.
- If the geometry is a valid [Polygon](#) in a geographic SRS, the result is the geodetic area of the polygon in that SRS, in square meters.
- If the geometry is a valid [MultiPolygon](#) in a geographic SRS, the result is the sum of geodetic area of the polygons in that SRS, in square meters.
- If an area computation results in [+inf](#), an [ER_DATA_OUT_OF_RANGE](#) error occurs.
- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If a longitude argument is not in the range $(-180, 180]$, an [ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE](#) error occurs ([ER_LONGITUDE_OUT_OF_RANGE](#) prior to MySQL 8.0.12).

- If a latitude argument is not in the range $[-90, 90]$, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Prior to MySQL 8.0.13, `ST_Area()` handles its arguments as described in the introduction to this section, with these exceptions:

- For arguments of dimension 0 or 1, the result is 0.
- If a geometry is empty, the return value is 0 rather than `NULL`.
- For a geometry collection, the result is the sum of the area values of all components. If the geometry collection is empty, its area is returned as 0.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```
mysql> SET @poly =
      'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';
mysql> SELECT ST_Area(ST_GeomFromText(@poly));
+-----+
| ST_Area(ST_GeomFromText(@poly)) |
+-----+
| 4 |
+-----+

mysql> SET @mpoly =
      'MultiPolygon(((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1)))';
mysql> SELECT ST_Area(ST_GeomFromText(@mpoly));
+-----+
| ST_Area(ST_GeomFromText(@mpoly)) |
+-----+
| 8 |
+-----+
```

- `ST_Centroid({poly|mpoly})`

Returns the mathematical centroid for the `Polygon` or `MultiPolygon` argument as a `Point`. The result is not guaranteed to be on the `MultiPolygon`.

This function processes geometry collections by computing the centroid point for components of highest dimension in the collection. Such components are extracted and made into a single `MultiPolygon`, `MultiLineString`, or `MultiPoint` for centroid computation.

`ST_Centroid()` handles its arguments as described in the introduction to this section, with these exceptions:

- The return value is `NULL` for the additional condition that the argument is an empty geometry collection.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```
mysql> SET @poly =
      ST_GeomFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),(5 5,7 5,7 7,5 7,5 5))');
mysql> SELECT ST_GeometryType(@poly),ST_AsText(ST_Centroid(@poly));
+-----+-----+
| ST_GeometryType(@poly) | ST_AsText(ST_Centroid(@poly)) |
+-----+-----+
| POLYGON                | POINT(4.958333333333333 4.958333333333333) |
+-----+-----+
```

- `ST_ExteriorRing(poly)`

Returns the exterior ring of the `Polygon` value *poly* as a `LineString`.

`ST_ExteriorRing()` handles its arguments as described in the introduction to this section.

```
mysql> SET @poly =
      'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly)));
+-----+
| ST_AsText(ST_ExteriorRing(ST_GeomFromText(@poly))) |
+-----+
| LINESTRING(0 0,0 3,3 3,3 0,0 0) |
+-----+
```

- `ST_InteriorRingN(poly, N)`

Returns the *N*-th interior ring for the `Polygon` value *poly* as a `LineString`. Rings are numbered beginning with 1.

`ST_InteriorRingN()` handles its arguments as described in the introduction to this section.

```
mysql> SET @poly =
      'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1));
+-----+
| ST_AsText(ST_InteriorRingN(ST_GeomFromText(@poly),1)) |
+-----+
| LINESTRING(1 1,1 2,2 2,2 1,1 1) |
+-----+
```

- `ST_NumInteriorRing(poly)`, `ST_NumInteriorRings(poly)`

Returns the number of interior rings in the `Polygon` value *poly*.

`ST_NumInteriorRing()` and `ST_NumInteriorRings()` handle their arguments as described in the introduction to this section.

```
mysql> SET @poly =
      'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';
mysql> SELECT ST_NumInteriorRings(ST_GeomFromText(@poly));
+-----+
| ST_NumInteriorRings(ST_GeomFromText(@poly)) |
+-----+
| 1 |
+-----+
```

12.17.7.5 GeometryCollection Property Functions

These functions return properties of `GeometryCollection` values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL` or any geometry argument is an empty geometry, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- Otherwise, the return value is non-`NULL`.

These functions are available for obtaining geometry collection properties:

- `ST_GeometryN(gc, N)`

Returns the *N*-th geometry in the [GeometryCollection](#) value *gc*. Geometries are numbered beginning with 1.

[ST_GeometryN\(\)](#) handles its arguments as described in the introduction to this section.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1));
+-----+
| ST_AsText(ST_GeometryN(ST_GeomFromText(@gc),1)) |
+-----+
| POINT(1 1) |
+-----+
```

- [ST_NumGeometries\(gc\)](#)

Returns the number of geometries in the [GeometryCollection](#) value *gc*.

[ST_NumGeometries\(\)](#) handles its arguments as described in the introduction to this section.

```
mysql> SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';
mysql> SELECT ST_NumGeometries(ST_GeomFromText(@gc));
+-----+
| ST_NumGeometries(ST_GeomFromText(@gc)) |
+-----+
| 2 |
+-----+
```

12.17.8 Spatial Operator Functions

OpenGIS proposes a number of functions that can produce geometries. They are designed to implement spatial operators.

These functions support all argument type combinations except those that are inapplicable according to the [Open Geospatial Consortium](#) specification.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is [NULL](#), the return value is [NULL](#).
- If any geometry argument is not a syntactically well-formed geometry, an [ER_GIS_INVALID_DATA](#) error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an [ER_SRS_NOT_FOUND](#) error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an [ER_GIS_DIFFERENT_SRIDS](#) error occurs.
- If any geometry argument has an SRID value for a geographic SRS, an [ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS](#) error occurs.
- Otherwise, the return value is non-[NULL](#).

These spatial operator functions are available:

- [ST_Buffer\(g, d\[, strategy1\[, strategy2\[, strategy3\]\]\)\]](#)

Returns a geometry that represents all points whose distance from the geometry value *g* is less than or equal to a distance of *d*.

If the geometry argument is empty, [ST_Buffer\(\)](#) returns an empty geometry.

If the distance is 0, [ST_Buffer\(\)](#) returns the geometry argument unchanged:

```
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 0));
```

```
+-----+
| ST_AsText(ST_Buffer(@pt, 0)) |
+-----+
| POINT(0 0) |
+-----+
```

`ST_Buffer()` supports negative distances for [Polygon](#) and [MultiPolygon](#) values, and for geometry collections containing [Polygon](#) or [MultiPolygon](#) values. The result may be an empty geometry.

`ST_Buffer()` permits up to three optional strategy arguments following the distance argument. Strategies influence buffer computation. These arguments are byte string values produced by the `ST_Buffer_Strategy()` function, to be used for point, join, and end strategies:

- Point strategies apply to [Point](#) and [MultiPoint](#) geometries. If no point strategy is specified, the default is `ST_Buffer_Strategy('point_circle', 32)`.
- Join strategies apply to [LineString](#), [MultiLineString](#), [Polygon](#), and [MultiPolygon](#) geometries. If no join strategy is specified, the default is `ST_Buffer_Strategy('join_round', 32)`.
- End strategies apply to [LineString](#) and [MultiLineString](#) geometries. If no end strategy is specified, the default is `ST_Buffer_Strategy('end_round', 32)`.

Up to one strategy of each type may be specified, and they may be given in any order.

`ST_Buffer()` handles its arguments as described in the introduction to this section, with these exceptions:

- For a negative distance for [Point](#), [MultiPoint](#), [LineString](#), and [MultiLineString](#) values, and for geometry collections not containing any [Polygon](#) or [MultiPolygon](#) values, an [ER_WRONG_ARGUMENTS](#) error occurs.
- If multiple strategies of a given type are specified, an [ER_WRONG_ARGUMENTS](#) error occurs.

```
mysql> SET @pt = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt_strategy = ST_Buffer_Strategy('point_square');
mysql> SELECT ST_AsText(ST_Buffer(@pt, 2, @pt_strategy));
```

```
+-----+
| ST_AsText(ST_Buffer(@pt, 2, @pt_strategy)) |
+-----+
| POLYGON((-2 -2,2 -2,2 2,-2 2,-2 -2)) |
+-----+
```

```
mysql> SET @ls = ST_GeomFromText('LINESTRING(0 0,0 5,5 5)');
mysql> SET @end_strategy = ST_Buffer_Strategy('end_flat');
mysql> SET @join_strategy = ST_Buffer_Strategy('join_round', 10);
mysql> SELECT ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy))
```

```
+-----+
| ST_AsText(ST_Buffer(@ls, 5, @end_strategy, @join_strategy)) |
+-----+
| POLYGON((5 5,5 10,0 10,-3.5355339059327373 8.535533905932738, |
| -5 5,-5 0,0 0,5 0,5 5)) |
+-----+
```

- `ST_Buffer_Strategy(strategy[, points_per_circle])`

This function returns a strategy byte string for use with `ST_Buffer()` to influence buffer computation.

Information about strategies is available at Boost.org.

The first argument must be a string indicating a strategy option:

- For point strategies, permitted values are `'point_circle'` and `'point_square'`.
- For join strategies, permitted values are `'join_round'` and `'join_miter'`.
- For end strategies, permitted values are `'end_round'` and `'end_flat'`.

If the first argument is `'point_circle'`, `'join_round'`, `'join_miter'`, or `'end_round'`, the `points_per_circle` argument must be given as a positive numeric value. The maximum `points_per_circle` value is the value of the `max_points_in_geometry` system variable.

For examples, see the description of `ST_Buffer()`.

`ST_Buffer_Strategy()` handles its arguments as described in the introduction to this section, with these exceptions:

- If any argument is invalid, an `ER_WRONG_ARGUMENTS` error occurs.
- If the first argument is `'point_square'` or `'end_flat'`, the `points_per_circle` argument must not be given or an `ER_WRONG_ARGUMENTS` error occurs.

- `ST_ConvexHull(g)`

Returns a geometry that represents the convex hull of the geometry value `g`.

This function computes a geometry's convex hull by first checking whether its vertex points are colinear. The function returns a linear hull if so, a polygon hull otherwise. This function processes geometry collections by extracting all vertex points of all components of the collection, creating a `MultiPoint` value from them, and computing its convex hull.

`ST_ConvexHull()` handles its arguments as described in the introduction to this section, with this exception:

- The return value is `NULL` for the additional condition that the argument is an empty geometry collection.

```
mysql> SET @g = 'MULTIPOINT(5 0,25 0,15 10,15 25)';
mysql> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText(@g)));
+-----+
| ST_AsText(ST_ConvexHull(ST_GeomFromText(@g))) |
+-----+
| POLYGON((5 0,25 0,15 25,5 0)) |
+-----+
```

- `ST_Difference(g1, g2)`

Returns a geometry that represents the point set difference of the geometry values `g1` and `g2`.

`ST_Difference()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_Difference(@g1, @g2));
+-----+
| ST_AsText(ST_Difference(@g1, @g2)) |
+-----+
| POINT(1 1) |
+-----+
```

- `ST_Intersection(g1, g2)`

Returns a geometry that represents the point set intersection of the geometry values *g1* and *g2*.

`ST_Intersection()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Intersection(@g1, @g2));
+-----+
| ST_AsText(ST_Intersection(@g1, @g2)) |
+-----+
| POINT(2 2) |
+-----+
```

- `ST_SymDifference(g1, g2)`

Returns a geometry that represents the point set symmetric difference of the geometry values *g1* and *g2*, which is defined as:

$$g1 \text{ symdifference } g2 := (g1 \text{ union } g2) \text{ difference } (g1 \text{ intersection } g2)$$

Or, in function call notation:

$$ST_SymDifference(g1, g2) = ST_Difference(ST_Union(g1, g2), ST_Intersection(g1, g2))$$

`ST_SymDifference()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_AsText(ST_SymDifference(@g1, @g2));
+-----+
| ST_AsText(ST_SymDifference(@g1, @g2)) |
+-----+
| MULTIPOINT((1 1),(2 2)) |
+-----+
```

- `ST_Transform(g, target_srid)`

Transforms a geometry from one spatial reference system (SRS) to another. The return value is a geometry of the same type as the input geometry with all coordinates transformed to the target SRID, *target_srid*. Transformation support is limited to geographic SRSs, unless the SRID of the

geometry argument is the same as the target SRID value, in which case the return value is the input geometry for any valid SRS.

`ST_Transform()` handles its arguments as described in the introduction to this section, with these exceptions:

- Geometry arguments that have an SRID value for a geographic SRS do not produce an error.
- If the geometry or target SRID argument has an SRID value that refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If the geometry is in an SRS that `ST_Transform()` cannot transform from, an `ER_TRANSFORM_SOURCE_SRS_NOT_SUPPORTED` error occurs.
- If the target SRID is in an SRS that `ST_Transform()` cannot transform to, an `ER_TRANSFORM_TARGET_SRS_NOT_SUPPORTED` error occurs.
- If the geometry is in an SRS that is not WGS 84 and has no TOWGS84 clause, an `ER_TRANSFORM_SOURCE_SRS_MISSING_TOWGS84` error occurs.
- If the target SRID is in an SRS that is not WGS 84 and has no TOWGS84 clause, an `ER_TRANSFORM_TARGET_SRS_MISSING_TOWGS84` error occurs.

`ST_SRID(g, target_srid)` and `ST_Transform(g, target_srid)` differ as follows:

- `ST_SRID()` changes the geometry SRID value without transforming its coordinates.
- `ST_Transform()` transforms the geometry coordinates in addition to changing its SRID value.

```
mysql> SET @p = ST_GeomFromText('POINT(52.381389 13.064444)', 4326);
mysql> SELECT ST_AsText(@p);
+-----+
| ST_AsText(@p) |
+-----+
| POINT(52.381389 13.064444) |
+-----+
mysql> SET @p = ST_Transform(@p, 4230);
mysql> SELECT ST_AsText(@p);
+-----+
| ST_AsText(@p) |
+-----+
| POINT(52.38208611407426 13.065520672345304) |
+-----+
```

- `ST_Union(g1, g2)`

Returns a geometry that represents the point set union of the geometry values `g1` and `g2`.

`ST_Union()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('LineString(1 1, 3 3)');
mysql> SET @g2 = ST_GeomFromText('LineString(1 3, 3 1)');
mysql> SELECT ST_AsText(ST_Union(@g1, @g2));
+-----+
| ST_AsText(ST_Union(@g1, @g2)) |
+-----+
| MULTILINESTRING((1 1,3 3),(1 3,3 1)) |
+-----+
```

In addition, [Section 12.17.7, “Geometry Property Functions”](#), discusses several functions that construct new geometries from existing ones. See that section for descriptions of these functions:

- `ST_Envelope(g)`
- `ST_StartPoint(ls)`

- `ST_EndPoint(ls)`
- `ST_PointN(ls, N)`
- `ST_ExteriorRing(poly)`
- `ST_InteriorRingN(poly, N)`
- `ST_GeometryN(gc, N)`

12.17.9 Functions That Test Spatial Relations Between Geometry Objects

The functions described in this section take two geometries as arguments and return a qualitative or quantitative relation between them.

MySQL implements two sets of functions using function names defined by the OpenGIS specification. One set tests the relationship between two geometry values using precise object shapes, the other set uses object minimum bounding rectangles (MBRs).

12.17.9.1 Spatial Relation Functions That Use Object Shapes

The OpenGIS specification defines the following functions to test the relationship between two geometry values `g1` and `g2`, using precise object shapes. The return values 1 and 0 indicate true and false, respectively, except for `ST_Distance()`, which returns distance values.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL` or any geometry argument is an empty geometry, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an `ER_GIS_DIFFERENT_SRIDS` error occurs.
- If any geometry argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude value is not in the range $(-180, 180]$, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (`ER_LONGITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).
 - If a latitude value is not in the range $[-90, 90]$, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These object-shape functions are available for testing geometry relationships:

- `ST_Contains(g1, g2)`

Returns 1 or 0 to indicate whether *g1* completely contains *g2*. This tests the opposite relationship as *ST_Within()*.

ST_Contains() handles its arguments as described in the introduction to this section.

- *ST_Crosses(g1, g2)*

Two geometries *spatially cross* if their spatial relation has the following properties:

- Unless *g1* and *g2* are both of dimension 1: *g1* crosses *g2* if the interior of *g2* has points in common with the interior of *g1*, but *g2* does not cover the entire interior of *g1*.
- If both *g1* and *g2* are of dimension 1: If the lines cross each other in a finite number of points (that is, no common line segments, only single points in common).

This function returns 1 or 0 to indicate whether *g1* spatially crosses *g2*.

ST_Crosses() handles its arguments as described in the introduction to this section except that the return value is *NULL* for these additional conditions:

- *g1* is of dimension 2 (*Polygon* or *MultiPolygon*).
- *g2* is of dimension 1 (*Point* or *MultiPoint*).
- *ST_Disjoint(g1, g2)*

Returns 1 or 0 to indicate whether *g1* is spatially disjoint from (does not intersect) *g2*.

ST_Disjoint() handles its arguments as described in the introduction to this section.

- *ST_Distance(g1, g2 [, unit])*

Returns the distance between *g1* and *g2*, measured in the length unit of the spatial reference system (SRS) of the geometry arguments, or in the unit of the optional *unit* argument if that is specified.

This function processes geometry collections by returning the shortest distance among all combinations of the components of the two geometry arguments.

ST_Distance() handles its geometry arguments as described in the introduction to this section, with these exceptions:

- *ST_Distance()* detects arguments in a geographic (ellipsoidal) spatial reference system and returns the geodetic distance on the ellipsoid. As of MySQL 8.0.18, *ST_Distance()* supports distance calculations for geographic SRS arguments of all geometry types. Prior to MySQL 8.0.18, the only permitted geographic argument types are *Point* and *Point*, or *Point* and *MultiPoint* (in any argument order). If called with other geometry type argument combinations in a geographic SRS, an *ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS* error occurs.
- If any argument is geometrically invalid, either the result is an undefined distance (that is, it can be any number), or an error occurs.
- If an intermediate or final result produces *NaN* or a negative number, an *ER_GIS_INVALID_DATA* error occurs.

As of MySQL 8.0.14, *ST_Distance()* permits an optional *unit* argument that specifies the linear unit for the returned distance value. These rules apply:

- If a unit is specified but not supported by MySQL, an *ER_UNIT_NOT_FOUND* error occurs.
- If a supported linear unit is specified and the SRID is 0, an *ER_GEOMETRY_IN_UNKNOWN_LENGTH_UNIT* error occurs.

- If a supported linear unit is specified and the SRID is not 0, the result is in that unit.
- If a unit is not specified, the result is in the unit of the SRS of the geometries, whether Cartesian or geographic. Currently, all MySQL SRSs are expressed in meters.

A unit is supported if it is found in the `INFORMATION_SCHEMA.ST_UNITS_OF_MEASURE` table. See [Section 25.37, “The INFORMATION_SCHEMA ST_UNITS_OF_MEASURE Table”](#).

```
mysql> SET @g1 = Point(1,1);
mysql> SET @g2 = Point(2,2);
mysql> SELECT ST_Distance(@g1, @g2);
+-----+
| ST_Distance(@g1, @g2) |
+-----+
| 1.4142135623730951 |
+-----+

mysql> SET @g1 = ST_GeomFromText('POINT(1 1)', 4326);
mysql> SET @g2 = ST_GeomFromText('POINT(2 2)', 4326);
mysql> SELECT ST_Distance(@g1, @g2);
+-----+
| ST_Distance(@g1, @g2) |

+-----+
```

For the special case of distance calculations on a sphere, see the `ST_Distance_Sphere()` function.

- `ST_Equals(g1, g2)`

Returns 1 or 0 to indicate whether *g1* is spatially equal to *g2*.

`ST_Equals()` handles its arguments as described in the introduction to this section, except that it does not return `NULL` for empty geometry arguments.

```
mysql> SET @g1 = Point(1,1), @g2 = Point(2,2);
mysql> SELECT ST_Equals(@g1, @g1), ST_Equals(@g1, @g2);
+-----+-----+
| ST_Equals(@g1, @g1) | ST_Equals(@g1, @g2) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

- `ST_Intersects(g1, g2)`

Returns 1 or 0 to indicate whether *g1* spatially intersects *g2*.

`ST_Intersects()` handles its arguments as described in the introduction to this section.

- `ST_Overlaps(g1, g2)`

Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether *g1* spatially overlaps *g2*.

`ST_Overlaps()` handles its arguments as described in the introduction to this section except that the return value is `NULL` for the additional condition that the dimensions of the two geometries are not equal.

- `ST_Touches(g1, g2)`

Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether *g1* spatially touches *g2*.

`ST_Touches()` handles its arguments as described in the introduction to this section except that the return value is `NULL` for the additional condition that both geometries are of dimension 0 (`Point` or `MultiPoint`).

- `ST_Within(g1, g2)`

Returns 1 or 0 to indicate whether *g1* is spatially within *g2*. This tests the opposite relationship as `ST_Contains()`.

`ST_Within()` handles its arguments as described in the introduction to this section.

12.17.9.2 Spatial Relation Functions That Use Minimum Bounding Rectangles

MySQL provides several MySQL-specific functions that test the relationship between minimum bounding rectangles (MBRs) of two geometries *g1* and *g2*. The return values 1 and 0 indicate true and false, respectively.

The bounding box of a point is interpreted as a point that is both boundary and interior.

The bounding box of a straight horizontal or vertical line is interpreted as a line where the interior of the line is also boundary. The endpoints are boundary points.

If any of the parameters are geometry collections, the interior, boundary, and exterior of those parameters are those of the union of all elements in the collection.

Functions in this section detect arguments in either Cartesian or geographic spatial reference systems (SRSs), and return results appropriate to the SRS.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL` or an empty geometry, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an `ER_GIS_DIFFERENT_SRIDS` error occurs.
- If any argument is geometrically invalid, either the result is true or false (it is undefined which), or an error occurs.
- For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

- If a longitude value is not in the range $(-180, 180]$, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (`ER_LONGITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).
- If a latitude value is not in the range $[-90, 90]$, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- Otherwise, the return value is non-`NULL`.

These MBR functions are available for testing geometry relationships:

- `MBRContains(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* contains the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRWithin()`.

`MBRContains()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRContains(@g1,@g2), MBRWithin(@g2,@g1);
```

MBRContains(@g1,@g2)	MBRWithin(@g2,@g1)
1	1

- `MBRCoveredBy(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* is covered by the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRCovers()`.

`MBRCoveredBy()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Point(1 1)');
mysql> SELECT MBRCovers(@g1,@g2), MBRCoveredBy(@g1,@g2);
```

MBRCovers(@g1,@g2)	MBRCoveredBy(@g1,@g2)
1	0

```
mysql> SELECT MBRCovers(@g2,@g1), MBRCoveredBy(@g2,@g1);
```

MBRCovers(@g2,@g1)	MBRCoveredBy(@g2,@g1)
0	1

- `MBRCovers(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* covers the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRCoveredBy()`. See the description of `MBRCoveredBy()` for examples.

`MBRCovers()` handles its arguments as described in the introduction to this section.

- `MBRDisjoint(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are disjoint (do not intersect).

`MBRDisjoint()` handles its arguments as described in the introduction to this section.

- `MBREquals(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* are the same.

`MBREquals()` handles its arguments as described in the introduction to this section, except that it does not return `NULL` for empty geometry arguments.

- `MBRIntersects(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* intersect.

`MBRIntersects()` handles its arguments as described in the introduction to this section.

- `MBROverlaps(g1, g2)`

Two geometries *spatially overlap* if they intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* overlap.

`MBROverlaps()` handles its arguments as described in the introduction to this section.

- `MBRTouches(g1, g2)`

Two geometries *spatially touch* if their interiors do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

This function returns 1 or 0 to indicate whether the minimum bounding rectangles of the two geometries *g1* and *g2* touch.

`MBRTouches()` handles its arguments as described in the introduction to this section.

- `MBRWithin(g1, g2)`

Returns 1 or 0 to indicate whether the minimum bounding rectangle of *g1* is within the minimum bounding rectangle of *g2*. This tests the opposite relationship as `MBRContains()`.

`MBRWithin()` handles its arguments as described in the introduction to this section.

```
mysql> SET @g1 = ST_GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
mysql> SET @g2 = ST_GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
mysql> SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+-----+-----+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+-----+-----+
| 1 | 0 |
+-----+-----+
```

12.17.10 Spatial Geohash Functions

Geohash is a system for encoding latitude and longitude coordinates of arbitrary precision into a text string. Geohash values are strings that contain only characters chosen from "0123456789bcdefghjkmnpqrstuvxyz".

The functions in this section enable manipulation of geohash values, which provides applications the capabilities of importing and exporting geohash data, and of indexing and searching geohash values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any argument is invalid, an error occurs.
- If any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude argument is not in the range $(-180, 180]$, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (`ER_LONGITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).
 - If a latitude argument is not in the range $[-90, 90]$, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

- If any point argument does not have SRID 0 or 4326, an `ER_SRS_NOT_FOUND` error occurs. `point` argument SRID validity is not checked.
- If any SRID argument refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- If any SRID argument is not within the range of a 32-bit unsigned integer, an `ER_DATA_OUT_OF_RANGE` error occurs.
- Otherwise, the return value is non-`NULL`.

These geohash functions are available:

- `ST_GeoHash(longitude, latitude, max_length), ST_GeoHash(point, max_length)`

Returns a geohash string in the connection character set and collation.

For the first syntax, the `longitude` must be a number in the range $[-180, 180]$, and the `latitude` must be a number in the range $[-90, 90]$. For the second syntax, a `POINT` value is required, where the X and Y coordinates are in the valid ranges for longitude and latitude, respectively.

The resulting string is no longer than `max_length` characters, which has an upper limit of 100. The string might be shorter than `max_length` characters because the algorithm that creates the geohash value continues until it has created a string that is either an exact representation of the location or `max_length` characters, whichever comes first.

`ST_GeoHash()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_GeoHash(180,0,10), ST_GeoHash(-180,-90,15);
+-----+-----+
| ST_GeoHash(180,0,10) | ST_GeoHash(-180,-90,15) |
+-----+-----+
| xbpbbpbbpbb       | 0000000000000000       |
+-----+-----+
```

- `ST_LatFromGeoHash(geohash_str)`

Returns the latitude from a geohash string value, as a double-precision number in the range $[-90, 90]$.

The `ST_LatFromGeoHash()` decoding function reads no more than 433 characters from the `geohash_str` argument. That represents the upper limit on information in the internal representation of coordinate values. Characters past the 433rd are ignored, even if they are otherwise illegal and produce an error.

`ST_LatFromGeoHash()` handles its arguments as described in the introduction to this section.

```
mysql> SELECT ST_LatFromGeoHash(ST_GeoHash(45,-20,10));
```

```

+-----+
| ST_LatFromGeoHash(ST_GeoHash(45,-20,10)) |
+-----+
|                                           -20 |
+-----+

```

- `ST_LongFromGeoHash(geohash_str)`

Returns the longitude from a geohash string value, as a double-precision number in the range $[-180, 180]$.

The remarks in the description of `ST_LatFromGeoHash()` regarding the maximum number of characters processed from the `geohash_str` argument also apply to `ST_LongFromGeoHash()`.

`ST_LongFromGeoHash()` handles its arguments as described in the introduction to this section.

```

mysql> SELECT ST_LongFromGeoHash(ST_GeoHash(45,-20,10));
+-----+
| ST_LongFromGeoHash(ST_GeoHash(45,-20,10)) |
+-----+
|                                           45 |
+-----+

```

- `ST_PointFromGeoHash(geohash_str, srid)`

Returns a `POINT` value containing the decoded geohash value, given a geohash string value.

The X and Y coordinates of the point are the longitude in the range $[-180, 180]$ and the latitude in the range $[-90, 90]$, respectively.

The `srid` argument is an 32-bit unsigned integer.

The remarks in the description of `ST_LatFromGeoHash()` regarding the maximum number of characters processed from the `geohash_str` argument also apply to `ST_PointFromGeoHash()`.

`ST_PointFromGeoHash()` handles its arguments as described in the introduction to this section.

```

mysql> SET @gh = ST_GeoHash(45,-20,10);
mysql> SELECT ST_AsText(ST_PointFromGeoHash(@gh,0));
+-----+
| ST_AsText(ST_PointFromGeoHash(@gh,0)) |
+-----+
| POINT(45 -20) |
+-----+

```

12.17.11 Spatial GeoJSON Functions

This section describes functions for converting between GeoJSON documents and spatial values. GeoJSON is an open standard for encoding geometric/geographical features. For more information, see <http://geojson.org>. The functions discussed here follow GeoJSON specification revision 1.0.

GeoJSON supports the same geometric/geographic data types that MySQL supports. Feature and FeatureCollection objects are not supported, except that geometry objects are extracted from them. CRS support is limited to values that identify an SRID.

MySQL also supports a native `JSON` data type and a set of SQL functions to enable operations on JSON values. For more information, see [Section 11.5, “The JSON Data Type”](#), and [Section 12.18, “JSON Functions”](#).

- `ST_AsGeoJSON(g [, max_dec_digits [, options]])`

Generates a GeoJSON object from the geometry `g`. The object string has the connection character set and collation.

If any argument is `NULL`, the return value is `NULL`. If any non-`NULL` argument is invalid, an error occurs.

max_dec_digits, if specified, limits the number of decimal digits for coordinates and causes rounding of output. If not specified, this argument defaults to its maximum value of $2^{32} - 1$. The minimum is 0.

options, if specified, is a bitmask. The following table shows the permitted flag values. If the geometry argument has an SRID of 0, no CRS object is produced even for those flag values that request one.

Flag Value	Meaning
0	No options. This is the default if <i>options</i> is not specified.
1	Add a bounding box to the output.
2	Add a short-format CRS URN to the output. The default format is a short format (<code>EPSG:srid</code>).
4	Add a long-format CRS URN (<code>urn:ogc:def:crs:EPSG::srid</code>). This flag overrides flag 2. For example, option values of 5 and 7 mean the same (add a bounding box and a long-format CRS URN).

```
mysql> SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(11.1111 12.2222)'),2);
+-----+
| ST_AsGeoJSON(ST_GeomFromText('POINT(11.1111 12.2222)'),2) |
+-----+
| {"type": "Point", "coordinates": [11.11, 12.22]}           |
+-----+
```

- `ST_GeomFromGeoJSON(str [, options [, srid]])`

Parses a string *str* representing a GeoJSON object and returns a geometry.

If any argument is `NULL`, the return value is `NULL`. If any non-`NULL` argument is invalid, an error occurs.

options, if given, describes how to handle GeoJSON documents that contain geometries with coordinate dimensions higher than 2. The following table shows the permitted *options* values.

Option Value	Meaning
1	Reject the document and produce an error. This is the default if <i>options</i> is not specified.

Option Value	Meaning
2, 3, 4	Accept the document and strip off the coordinates for higher coordinate dimensions.

`options` values of 2, 3, and 4 currently produce the same effect. If geometries with coordinate dimensions higher than 2 are supported in the future, these values will produce different effects.

The `srid` argument, if given, must be a 32-bit unsigned integer. If not given, the geometry return value has an SRID of 4326.

If `srid` refers to an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.

For geographic SRS geometry arguments, if any argument has a longitude or latitude that is out of range, an error occurs:

- If a longitude value is not in the range $(-180, 180]$, an `ER_LONGITUDE_OUT_OF_RANGE` error occurs.
- If a latitude value is not in the range $[-90, 90]$, an `ER_LATITUDE_OUT_OF_RANGE` error occurs.

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

GeoJSON geometry, feature, and feature collection objects may have a `crs` property. The parsing function parses named CRS URNs in the `urn:ogc:def:crs:EPSG::srid` and `EPSG:srid` namespaces, but not CRSs given as link objects. Also, `urn:ogc:def:crs:OGC:1.3:CRS84` is recognized as SRID 4326. If an object has a CRS that is not understood, an error occurs, with the exception that if the optional `srid` argument is given, any CRS is ignored even if it is invalid.

If a `crs` member that specifies an SRID different from the top-level object SRID is found at a lower level of the GeoJSON document, an `ER_INVALID_GEOJSON_CRIS_NOT_TOP_LEVEL` error occurs.

As specified in the GeoJSON specification, parsing is case sensitive for the `type` member of the GeoJSON input (`Point`, `LineString`, and so forth). The specification is silent regarding case sensitivity for other parsing, which in MySQL is not case-sensitive.

This example shows the parsing result for a simple GeoJSON object. Observe that the order of coordinates depends on the SRID used.

```
mysql> SET @json = '{ "type": "Point", "coordinates": [102.0, 0.0] }';
mysql> SELECT ST_AsText(ST_GeomFromGeoJSON(@json));
+-----+
| ST_AsText(ST_GeomFromGeoJSON(@json)) |
+-----+
| POINT(0 102)                          |
+-----+
mysql> SELECT ST_SRID(ST_GeomFromGeoJSON(@json));
+-----+
| ST_SRID(ST_GeomFromGeoJSON(@json)) |
+-----+
| 4326                                |
+-----+
mysql> SELECT ST_AsText(ST_SRID(ST_GeomFromGeoJSON(@json),0));
+-----+
| ST_AsText(ST_SRID(ST_GeomFromGeoJSON(@json),0)) |
+-----+
| POINT(102 0)                                   |
+-----+
```

12.17.12 Spatial Convenience Functions

The functions in this section provide convenience operations on geometry values.

Unless otherwise specified, functions in this section handle their arguments as follows:

- If any argument is `NULL`, the return value is `NULL`.
- If any geometry argument is not a syntactically well-formed geometry, an `ER_GIS_INVALID_DATA` error occurs.
- If any geometry argument is a syntactically well-formed geometry in an undefined spatial reference system (SRS), an `ER_SRS_NOT_FOUND` error occurs.
- For functions that take multiple geometry arguments, if those arguments do not have the same SRID, an `ER_GIS_DIFFERENT_SRIDS` error occurs.
- Otherwise, the return value is non-`NULL`.

These convenience functions are available:

- `ST_Distance_Sphere(g1, g2 [, radius])`

Returns the minimum spherical distance between `Point` or `MultiPoint` arguments on a sphere, in meters. (For general-purpose distance calculations, see the `ST_Distance()` function.) The optional `radius` argument should be given in meters.

If both geometry parameters are valid Cartesian `Point` or `MultiPoint` values in SRID 0, the return value is shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is 6,370,986 meters, Point X and Y coordinates are interpreted as longitude and latitude, respectively, in degrees.

If both geometry parameters are valid `Point` or `MultiPoint` values in a geographic spatial reference system (SRS), the return value is the shortest distance between the two geometries on a sphere with the provided radius. If omitted, the default radius is equal to the mean radius, defined as $(2a+b)/3$, where a is the semi-major axis and b is the semi-minor axis of the SRS.

`ST_Distance_Sphere()` handles its arguments as described in the introduction to this section, with these exceptions:

- Supported geometry argument combinations are `Point` and `Point`, or `Point` and `MultiPoint` (in any argument order). If at least one of the geometries is neither `Point` nor `MultiPoint`, and its SRID is 0, an `ER_NOT_IMPLEMENTED_FOR_CARTESIAN_SRS` error occurs. If at least one of the geometries is neither `Point` nor `MultiPoint`, and its SRID refers to a geographic SRS, an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs. If any geometry refers to a projected SRS, an `ER_NOT_IMPLEMENTED_FOR_PROJECTED_SRS` error occurs.
- If any argument has a longitude or latitude that is out of range, an error occurs:
 - If a longitude argument is not in the range $(-180, 180]$, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (`ER_LONGITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).
 - If a latitude argument is not in the range $[-90, 90]$, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

- If the `radius` argument is present but not positive, an `ER_NONPOSITIVE_RADIUS` error occurs.
- If the distance exceeds the range of a double-precision number, an `ER_STD_OVERFLOW_ERROR` error occurs.

```
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
```

```
mysql> SET @pt2 = ST_GeomFromText('POINT(180 0)');
mysql> SELECT ST_Distance_Sphere(@pt1, @pt2);
+-----+
| ST_Distance_Sphere(@pt1, @pt2) |
+-----+
| 20015042.813723423 |
+-----+
```

- `ST_IsValid(g)`

Returns 1 if the argument is geometrically valid, 0 if the argument is not geometrically valid. Geometry validity is defined by the OGC specification.

The only valid empty geometry is represented in the form of an empty geometry collection value. `ST_IsValid()` returns 1 in this case. MySQL does not support GIS `EMPTY` values such as `POINT EMPTY`.

`ST_IsValid()` handles its arguments as described in the introduction to this section, with this exception:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If a longitude argument is not in the range $(-180, 180]$, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (`ER_LONGITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).
 - If a latitude argument is not in the range $[-90, 90]$, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

Ranges shown are in degrees. If an SRS uses another unit, the range uses the corresponding values in its unit. The exact range limits deviate slightly due to floating-point arithmetic.

```
mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0,-0.00 0,0.0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_IsValid(@ls1);
+-----+
| ST_IsValid(@ls1) |
+-----+
| 0 |
+-----+
mysql> SELECT ST_IsValid(@ls2);
+-----+
| ST_IsValid(@ls2) |
+-----+
| 1 |
+-----+
```

- `ST_MakeEnvelope(pt1, pt2)`

Returns the rectangle that forms the envelope around two points, as a `Point`, `LineString`, or `Polygon`.

Calculations are done using the Cartesian coordinate system rather than on a sphere, spheroid, or on earth.

Given two points `pt1` and `pt2`, `ST_MakeEnvelope()` creates the result geometry on an abstract plane like this:

- If `pt1` and `pt2` are equal, the result is the point `pt1`.
- Otherwise, if `(pt1, pt2)` is a vertical or horizontal line segment, the result is the line segment `(pt1, pt2)`.
- Otherwise, the result is a polygon using `pt1` and `pt2` as diagonal points.

The result geometry has an SRID of 0.

`ST_MakeEnvelope()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the arguments are not `Point` values, an `ER_WRONG_ARGUMENTS` error occurs.
- An `ER_GIS_INVALID_DATA` error occurs for the additional condition that any coordinate value of the two points is infinite or `NaN`.
- If any geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```
mysql> SET @pt1 = ST_GeomFromText('POINT(0 0)');
mysql> SET @pt2 = ST_GeomFromText('POINT(1 1)');
mysql> SELECT ST_AsText(ST_MakeEnvelope(@pt1, @pt2));
+-----+
| ST_AsText(ST_MakeEnvelope(@pt1, @pt2)) |
+-----+
| POLYGON((0 0,1 0,1 1,0 1,0 0)) |
+-----+
```

- `ST_Simplify(g, max_distance)`

Simplifies a geometry using the Douglas-Peucker algorithm and returns a simplified value of the same type.

The geometry may be any geometry type, although the Douglas-Peucker algorithm may not actually process every type. A geometry collection is processed by giving its components one by one to the simplification algorithm, and the returned geometries are put into a geometry collection as result.

The `max_distance` argument is the distance (in units of the input coordinates) of a vertex to other segments to be removed. Vertices within this distance of the simplified linestring are removed.

According to Boost.Geometry, geometries might become invalid as a result of the simplification process, and the process might create self-intersections. To check the validity of the result, pass it to `ST_IsValid()`.

`ST_Simplify()` handles its arguments as described in the introduction to this section, with this exception:

- If the `max_distance` argument is not positive, or is `NaN`, an `ER_WRONG_ARGUMENTS` error occurs.

```
mysql> SET @g = ST_GeomFromText('LINESTRING(0 0,0 1,1 1,1 2,2 2,2 3,3 3)');
mysql> SELECT ST_AsText(ST_Simplify(@g, 0.5));
```

```

+-----+
| ST_AsText(ST_Simplify(@g, 0.5)) |
+-----+
| LINESTRING(0 0,0 1,1 1,2 3,3 3) |
+-----+
mysql> SELECT ST_AsText(ST_Simplify(@g, 1.0));
+-----+
| ST_AsText(ST_Simplify(@g, 1.0)) |
+-----+
| LINESTRING(0 0,3 3) |
+-----+

```

- `ST_Validate(g)`

Validates a geometry according to the OGC specification. A geometry can be syntactically well-formed (WKB value plus SRID) but geometrically invalid. For example, this polygon is geometrically invalid: `POLYGON((0 0, 0 0, 0 0, 0 0, 0 0))`

`ST_Validate()` returns the geometry if it is syntactically well-formed and is geometrically valid, `NULL` if the argument is not syntactically well-formed or is not geometrically valid or is `NULL`.

`ST_Validate()` can be used to filter out invalid geometry data, although at a cost. For applications that require more precise results not tainted by invalid data, this penalty may be worthwhile.

If the geometry argument is valid, it is returned as is, except that if an input `Polygon` or `MultiPolygon` has clockwise rings, those rings are reversed before checking for validity. If the geometry is valid, the value with the reversed rings is returned.

The only valid empty geometry is represented in the form of an empty geometry collection value. `ST_Validate()` returns it directly without further checks in this case.

As of MySQL 8.0.13, `ST_Validate()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry has a geographic SRS with a longitude or latitude that is out of range, an error occurs:
 - If a longitude argument is not in the range $(-180, 180]$, an `ER_GEOMETRY_PARAM_LONGITUDE_OUT_OF_RANGE` error occurs (`ER_LONGITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).
 - If a latitude argument is not in the range $[-90, 90]$, an `ER_GEOMETRY_PARAM_LATITUDE_OUT_OF_RANGE` error occurs (`ER_LATITUDE_OUT_OF_RANGE` prior to MySQL 8.0.12).

Ranges shown are in degrees. The exact range limits deviate slightly due to floating-point arithmetic.

Prior to MySQL 8.0.13, `ST_Validate()` handles its arguments as described in the introduction to this section, with these exceptions:

- If the geometry is not syntactically well-formed, the return value is `NULL`. An `ER_GIS_INVALID_DATA` error does not occur.
- If the geometry has an SRID value for a geographic spatial reference system (SRS), an `ER_NOT_IMPLEMENTED_FOR_GEOGRAPHIC_SRS` error occurs.

```

mysql> SET @ls1 = ST_GeomFromText('LINESTRING(0 0)');
mysql> SET @ls2 = ST_GeomFromText('LINESTRING(0 0, 1 1)');
mysql> SELECT ST_AsText(ST_Validate(@ls1));
+-----+
| ST_AsText(ST_Validate(@ls1)) |
+-----+
| NULL |
+-----+

```

```

+-----+
mysql> SELECT ST_AsText(ST_Validate(@ls2));
+-----+
| ST_AsText(ST_Validate(@ls2)) |
+-----+
| LINESTRING(0 0,1 1)          |
+-----+

```

12.18 JSON Functions

The functions described in this section perform operations on JSON values. For discussion of the [JSON](#) data type and additional examples showing how to use these functions, see [Section 11.5, “The JSON Data Type”](#).

For functions that take a JSON argument, an error occurs if the argument is not a valid JSON value. Arguments parsed as JSON are indicated by *json_doc*; arguments indicated by *val* are not parsed.

A set of spatial functions for operating on GeoJSON values is also available. See [Section 12.17.11, “Spatial GeoJSON Functions”](#).

12.18.1 JSON Function Reference

Table 12.22 JSON Functions

Name	Description
<code>-></code>	Return value from JSON column after evaluating path; equivalent to <code>JSON_EXTRACT()</code> .
<code>->></code>	Return value from JSON column after evaluating path and unquoting the result; equivalent to <code>JSON_UNQUOTE(JSON_EXTRACT())</code> .
<code>JSON_ARRAY()</code>	Create JSON array
<code>JSON_ARRAY_APPEND()</code>	Append data to JSON document
<code>JSON_ARRAY_INSERT()</code>	Insert into JSON array
<code>JSON_CONTAINS()</code>	Whether JSON document contains specific object at path
<code>JSON_CONTAINS_PATH()</code>	Whether JSON document contains any data at path
<code>JSON_DEPTH()</code>	Maximum depth of JSON document
<code>JSON_EXTRACT()</code>	Return data from JSON document
<code>JSON_INSERT()</code>	Insert data into JSON document
<code>JSON_KEYS()</code>	Array of keys from JSON document
<code>JSON_LENGTH()</code>	Number of elements in JSON document
<code>JSON_MERGE()</code> (deprecated)	Merge JSON documents, preserving duplicate keys. Deprecated synonym for <code>JSON_MERGE_PRESERVE()</code>
<code>JSON_MERGE_PATCH()</code>	Merge JSON documents, replacing values of duplicate keys
<code>JSON_MERGE_PRESERVE()</code>	Merge JSON documents, preserving duplicate keys
<code>JSON_OBJECT()</code>	Create JSON object
<code>JSON_OVERLAPS()</code> (introduced 8.0.17)	Compares two JSON documents, returns TRUE (1) if these have any key-value pairs or array elements in common, otherwise FALSE (0)
<code>JSON_PRETTY()</code>	Print a JSON document in human-readable format
<code>JSON_QUOTE()</code>	Quote JSON document
<code>JSON_REMOVE()</code>	Remove data from JSON document

Name	Description
<code>JSON_REPLACE()</code>	Replace values in JSON document
<code>JSON_SCHEMA_VALID()</code> (introduced 8.0.17)	Validate JSON document against JSON schema; returns TRUE/1 if document validates against schema, or FALSE/0 if it does not
<code>JSON_SCHEMA_VALIDATION_REPORT()</code> (introduced 8.0.17)	Validate JSON document against JSON schema; returns report in JSON format on outcome on validation including success or failure and reasons for failure
<code>JSON_SEARCH()</code>	Path to value within JSON document
<code>JSON_SET()</code>	Insert data into JSON document
<code>JSON_STORAGE_FREE()</code>	Freed space within binary representation of JSON column value following partial update
<code>JSON_STORAGE_SIZE()</code>	Space used for storage of binary representation of a JSON document
<code>JSON_TABLE()</code>	Return data from a JSON expression as a relational table
<code>JSON_TYPE()</code>	Type of JSON value
<code>JSON_UNQUOTE()</code>	Unquote JSON value
<code>JSON_VALID()</code>	Whether JSON value is valid
<code>JSON_VALUE()</code> (introduced 8.0.21)	Extract value from JSON document at location pointed to by path provided; return this value as VARCHAR(512) or specified type
<code>MEMBER OF()</code> (introduced 8.0.17)	Returns true (1) if first operand matches any element of JSON array passed as second operand, otherwise returns false (0)

MySQL supports two aggregate JSON functions `JSON_ARRAYAGG()` and `JSON_OBJECTAGG()`. See [Section 12.20, “Aggregate Functions”](#), for descriptions of these.

MySQL also supports “pretty-printing” of JSON values in an easy-to-read format, using the `JSON_PRETTY()` function. You can see how much storage space a given JSON value takes up, and how much space remains for additional storage, using `JSON_STORAGE_SIZE()` and `JSON_STORAGE_FREE()`, respectively. For complete descriptions of these functions, see [Section 12.18.8, “JSON Utility Functions”](#).

12.18.2 Functions That Create JSON Values

The functions listed in this section compose JSON values from component elements.

- `JSON_ARRAY([val[, val] ...])`

Evaluates a (possibly empty) list of values and returns a JSON array containing those values.

```
mysql> SELECT JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME());
+-----+
| JSON_ARRAY(1, "abc", NULL, TRUE, CURTIME()) |
+-----+
| [1, "abc", null, true, "11:30:24.000000"] |
+-----+
```

- `JSON_OBJECT([key, val[, key, val] ...])`

Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs. An error occurs if any key name is `NULL` or the number of arguments is odd.

```
mysql> SELECT JSON_OBJECT('id', 87, 'name', 'carrot');
```

```
+-----+
| JSON_OBJECT('id', 87, 'name', 'carrot') |
+-----+
| {"id": 87, "name": "carrot"}           |
+-----+
```

- `JSON_QUOTE(string)`

Quotes a string as a JSON value by wrapping it with double quote characters and escaping interior quote and other characters, then returning the result as a `utf8mb4` string. Returns `NULL` if the argument is `NULL`.

This function is typically used to produce a valid JSON string literal for inclusion within a JSON document.

Certain special characters are escaped with backslashes per the escape sequences shown in [Table 12.23, “JSON_UNQUOTE\(\) Special Character Escape Sequences”](#).

```
mysql> SELECT JSON_QUOTE('null'), JSON_QUOTE('"null"');
+-----+-----+
| JSON_QUOTE('null') | JSON_QUOTE('"null"') |
+-----+-----+
| "null"             | "\"null\""           |
+-----+-----+
mysql> SELECT JSON_QUOTE('[1, 2, 3]');
+-----+
| JSON_QUOTE('[1, 2, 3]') |
+-----+
| "[1, 2, 3]"            |
+-----+
```

You can also obtain JSON values by casting values of other types to the `JSON` type using `CAST(value AS JSON)`; see [Converting between JSON and non-JSON values](#), for more information.

Two aggregate functions generating JSON values are available. `JSON_ARRAYAGG()` returns a result set as a single JSON array, and `JSON_OBJECTAGG()` returns a result set as a single JSON object. For more information, see [Section 12.20, “Aggregate Functions”](#).

12.18.3 Functions That Search JSON Values

The functions in this section perform search or comparison operations on JSON values to extract data from them, report whether data exists at a location within them, or report the path to data within them. The `MEMBER OF()` operator is also documented herein.

- `JSON_CONTAINS(target, candidate[, path])`

Indicates by returning 1 or 0 whether a given *candidate* JSON document is contained within a *target* JSON document, or—if a *path* argument was supplied—whether the candidate is found at a specific path within the target. Returns `NULL` if any argument is `NULL`, or if the path argument does not identify a section of the target document. An error occurs if *target* or *candidate* is not a valid JSON document, or if the *path* argument is not a valid path expression or contains a `*` or `**` wildcard.

To check only whether any data exists at the path, use `JSON_CONTAINS_PATH()` instead.

The following rules define containment:

- A candidate scalar is contained in a target scalar if and only if they are comparable and are equal. Two scalar values are comparable if they have the same `JSON_TYPE()` types, with the exception that values of types `INTEGER` and `DECIMAL` are also comparable to each other.
- A candidate array is contained in a target array if and only if every element in the candidate is contained in some element of the target.

- A candidate nonarray is contained in a target array if and only if the candidate is contained in some element of the target.
- A candidate object is contained in a target object if and only if for each key in the candidate there is a key with the same name in the target and the value associated with the candidate key is contained in the value associated with the target key.

Otherwise, the candidate value is not contained in the target document.

Starting with MySQL 8.0.17, queries using `JSON_CONTAINS()` on `InnoDB` tables can be optimized using multi-valued indexes; see [Multi-Valued Indexes](#), for more information.

```
mysql> SET @j = '{"a": 1, "b": 2, "c": {"d": 4}}';
mysql> SET @j2 = '1';
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');
+-----+
| JSON_CONTAINS(@j, @j2, '$.a') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.b');
+-----+
| JSON_CONTAINS(@j, @j2, '$.b') |
+-----+
| 0 |
+-----+

mysql> SET @j2 = '{"d": 4}';
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.a');
+-----+
| JSON_CONTAINS(@j, @j2, '$.a') |
+-----+
| 0 |
+-----+
mysql> SELECT JSON_CONTAINS(@j, @j2, '$.c');
+-----+
| JSON_CONTAINS(@j, @j2, '$.c') |
+-----+
| 1 |
+-----+
```

- `JSON_CONTAINS_PATH(json_doc, one_or_all, path[, path] ...)`

Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, or `one_or_all` is not `'one'` or `'all'`.

To check for a specific value at a path, use `JSON_CONTAINS()` instead.

The return value is 0 if no specified path exists within the document. Otherwise, the return value depends on the `one_or_all` argument:

- `'one'`: 1 if at least one path exists within the document, 0 otherwise.
- `'all'`: 1 if all paths exist within the document, 0 otherwise.

```
mysql> SET @j = '{"a": 1, "b": 2, "c": {"d": 4}}';
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e');
+-----+
| JSON_CONTAINS_PATH(@j, 'one', '$.a', '$.e') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e');
+-----+
| JSON_CONTAINS_PATH(@j, 'all', '$.a', '$.e') |
+-----+
```

```
+-----+
|                                             0 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.c.d');
+-----+
| JSON_CONTAINS_PATH(@j, 'one', '$.c.d') |
+-----+
|                                             1 |
+-----+
mysql> SELECT JSON_CONTAINS_PATH(@j, 'one', '$.a.d');
+-----+
| JSON_CONTAINS_PATH(@j, 'one', '$.a.d') |
+-----+
|                                             0 |
+-----+
```

- `JSON_EXTRACT(json_doc, path[, path] ...)`

Returns data from a JSON document, selected from the parts of the document matched by the *path* arguments. Returns `NULL` if any argument is `NULL` or no paths locate a value in the document. An error occurs if the *json_doc* argument is not a valid JSON document or any *path* argument is not a valid path expression.

The return value consists of all values matched by the *path* arguments. If it is possible that those arguments could return multiple values, the matched values are autowrapped as an array, in the order corresponding to the paths that produced them. Otherwise, the return value is the single matched value.

```
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]') |
+-----+
| 20 |
+-----+
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[1]', '$[0]') |
+-----+
| [20, 10] |
+-----+
mysql> SELECT JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]');
+-----+
| JSON_EXTRACT('[10, 20, [30, 40]]', '$[2][*]') |
+-----+
| [30, 40] |
+-----+
```

MySQL supports the `->` operator as shorthand for this function as used with 2 arguments where the left hand side is a `JSON` column identifier (not an expression) and the right hand side is the JSON path to be matched within the column.

- *column->path*

The `->` operator serves as an alias for the `JSON_EXTRACT()` function when used with two arguments, a column identifier on the left and a JSON path on the right that is evaluated against the JSON document (the column value). You can use such expressions in place of column identifiers wherever they occur in SQL statements.

The two `SELECT` statements shown here produce the same output:

```
mysql> SELECT c, JSON_EXTRACT(c, "$.id"), g
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY JSON_EXTRACT(c, "$.name");
+-----+-----+-----+
| c | c->"$.id" | g |
+-----+-----+-----+
| {"id": "3", "name": "Barney"} | "3" | 3 |
```

```

| {"id": "4", "name": "Betty"} | "4" | 4 |
| {"id": "2", "name": "Wilma"} | "2" | 2 |
+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT c, c->"$.id", g
> FROM jemp
> WHERE c->"$.id" > 1
> ORDER BY c->"$.name";
+-----+-----+-----+
| c | c->"$.id" | g |
+-----+-----+-----+
| {"id": "3", "name": "Barney"} | "3" | 3 |
| {"id": "4", "name": "Betty"} | "4" | 4 |
| {"id": "2", "name": "Wilma"} | "2" | 2 |
+-----+-----+-----+
3 rows in set (0.00 sec)

```

This functionality is not limited to `SELECT`, as shown here:

```

mysql> ALTER TABLE jemp ADD COLUMN n INT;
Query OK, 0 rows affected (0.68 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> UPDATE jemp SET n=1 WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT c, c->"$.id", g, n
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY c->"$.name";
+-----+-----+-----+-----+
| c | c->"$.id" | g | n |
+-----+-----+-----+-----+
| {"id": "3", "name": "Barney"} | "3" | 3 | NULL |
| {"id": "4", "name": "Betty"} | "4" | 4 | 1 |
| {"id": "2", "name": "Wilma"} | "2" | 2 | NULL |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> DELETE FROM jemp WHERE c->"$.id" = "4";
Query OK, 1 row affected (0.04 sec)

mysql> SELECT c, c->"$.id", g, n
> FROM jemp
> WHERE JSON_EXTRACT(c, "$.id") > 1
> ORDER BY c->"$.name";
+-----+-----+-----+-----+
| c | c->"$.id" | g | n |
+-----+-----+-----+-----+
| {"id": "3", "name": "Barney"} | "3" | 3 | NULL |
| {"id": "2", "name": "Wilma"} | "2" | 2 | NULL |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)

```

(See [Indexing a Generated Column to Provide a JSON Column Index](#), for the statements used to create and populate the table just shown.)

This also works with JSON array values, as shown here:

```

mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10
> VALUES ("[3,10,5,17,44]", 33), ("[3,10,5,17,[22,44,66]]", 0);
Query OK, 1 row affected (0.04 sec)

mysql> SELECT a->"$[4]" FROM tj10;
+-----+
| a->"$[4]" |
+-----+

```

```
+-----+
| 44 |
| [22, 44, 66] |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM tj10 WHERE a->"$[0]" = 3;
+-----+-----+
| a | b |
+-----+-----+
| [3, 10, 5, 17, 44] | 33 |
| [3, 10, 5, 17, [22, 44, 66]] | 0 |
+-----+-----+
2 rows in set (0.00 sec)
```

Nested arrays are supported. An expression using `->` evaluates as `NULL` if no matching key is found in the target JSON document, as shown here:

```
mysql> SELECT * FROM tj10 WHERE a->"$[4][1]" IS NOT NULL;
+-----+-----+
| a | b |
+-----+-----+
| [3, 10, 5, 17, [22, 44, 66]] | 0 |
+-----+-----+

mysql> SELECT a->"$[4][1]" FROM tj10;
+-----+
| a->"$[4][1]" |
+-----+
| NULL |
| 44 |
+-----+
2 rows in set (0.00 sec)
```

This is the same behavior as seen in such cases when using `JSON_EXTRACT()`:

```
mysql> SELECT JSON_EXTRACT(a, "$[4][1]") FROM tj10;
+-----+
| JSON_EXTRACT(a, "$[4][1]") |
+-----+
| NULL |
| 44 |
+-----+
2 rows in set (0.00 sec)
```

- `column->>path`

This is an improved, unquoting extraction operator. Whereas the `->` operator simply extracts a value, the `->>` operator in addition unquotes the extracted result. In other words, given a `JSON` column value `column` and a path expression `path`, the following three expressions return the same value:

- `JSON_UNQUOTE(JSON_EXTRACT(column, path))`
- `JSON_UNQUOTE(column -> path)`
- `column->>path`

The `->>` operator can be used wherever `JSON_UNQUOTE(JSON_EXTRACT())` would be allowed. This includes (but is not limited to) `SELECT` lists, `WHERE` and `HAVING` clauses, and `ORDER BY` and `GROUP BY` clauses.

The next few statements demonstrate some `->>` operator equivalences with other expressions in the `mysql` client:

```
mysql> SELECT * FROM jemp WHERE g > 2;
+-----+-----+
| c | g |
+-----+-----+
```

```

| {"id": "3", "name": "Barney"} | 3 |
| {"id": "4", "name": "Betty"} | 4 |
+-----+-----+
2 rows in set (0.01 sec)

mysql> SELECT c->'$.name' AS name
->      FROM jemp WHERE g > 2;
+-----+
| name |
+-----+
| "Barney" |
| "Betty" |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT JSON_UNQUOTE(c->'$.name') AS name
->      FROM jemp WHERE g > 2;
+-----+
| name |
+-----+
| Barney |
| Betty |
+-----+
2 rows in set (0.00 sec)

mysql> SELECT c->>'$.name' AS name
->      FROM jemp WHERE g > 2;
+-----+
| name |
+-----+
| Barney |
| Betty |
+-----+
2 rows in set (0.00 sec)

```

See [Indexing a Generated Column to Provide a JSON Column Index](#), for the SQL statements used to create and populate the `jemp` table in the set of examples just shown.

This operator can also be used with JSON arrays, as shown here:

```

mysql> CREATE TABLE tj10 (a JSON, b INT);
Query OK, 0 rows affected (0.26 sec)

mysql> INSERT INTO tj10 VALUES
->      ('[3,10,5,"x",44]', 33),
->      ('[3,10,5,17,[22,"y",66]]', 0);
Query OK, 2 rows affected (0.04 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT a->"$[3]", a->"$[4][1]" FROM tj10;
+-----+-----+
| a->"$[3]" | a->"$[4][1]" |
+-----+-----+
| "x"      | NULL         |
| 17       | "y"          |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT a->>"$[3]", a->>"$[4][1]" FROM tj10;
+-----+-----+
| a->>"$[3]" | a->>"$[4][1]" |
+-----+-----+
| x         | NULL         |
| 17        | y            |
+-----+-----+
2 rows in set (0.00 sec)

```

As with `->`, the `->>` operator is always expanded in the output of `EXPLAIN`, as the following example demonstrates:

```

mysql> EXPLAIN SELECT c->>'$.name' AS name

```

```
-> FROM jemp WHERE g > 2\G
***** 1. row *****
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select
json_unquote(json_extract(`jtest`.`jemp`.`c`, '$.name')) AS `name` from
`jtest`.`jemp` where (`jtest`.`jemp`.`g` > 2)
1 row in set (0.00 sec)
```

This is similar to how MySQL expands the `->` operator in the same circumstances.

- `JSON_KEYS(json_doc[, path])`

Returns the keys from the top-level value of a JSON object as a JSON array, or, if a `path` argument is given, the top-level keys from the selected path. Returns `NULL` if any argument is `NULL`, the `json_doc` argument is not an object, or `path`, if given, does not locate an object. An error occurs if the `json_doc` argument is not a valid JSON document or the `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The result array is empty if the selected object is empty. If the top-level value has nested subobjects, the return value does not include keys from those subobjects.

```
mysql> SELECT JSON_KEYS('{ "a": 1, "b": { "c": 30 } }');
+-----+
| JSON_KEYS('{ "a": 1, "b": { "c": 30 } }') |
+-----+
| ["a", "b"] |
+-----+
mysql> SELECT JSON_KEYS('{ "a": 1, "b": { "c": 30 } }', '$.b');
+-----+
| JSON_KEYS('{ "a": 1, "b": { "c": 30 } }', '$.b') |
+-----+
| ["c"] |
+-----+
```

- `JSON_OVERLAPS(json_doc1, json_doc2)`

Compares two JSON documents. Returns true (1) if the two document have any key-value pairs or array elements in common. If both arguments are scalars, the function performs a simple equality test.

This function serves as counterpart to `JSON_CONTAINS()`, which requires all elements of the array searched for to be present in the array searched in. Thus, `JSON_CONTAINS()` performs an `AND` operation on search keys, while `JSON_OVERLAPS()` performs an `OR` operation.

Queries on JSON columns of `InnoDB` tables using `JSON_OVERLAPS()` in the `WHERE` clause can be optimized using multi-valued indexes. [Multi-Valued Indexes](#), provides detailed information and examples.

When comparing two arrays, `JSON_OVERLAPS()` returns true if they share one or more array elements in common, and false if they do not:

```
mysql> SELECT JSON_OVERLAPS("[1,3,5,7]", "[2,5,7]");
+-----+
| JSON_OVERLAPS("[1,3,5,7]", "[2,5,7]") |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS("[1,3,5,7]", "[2,6,7]");
+-----+
| JSON_OVERLAPS("[1,3,5,7]", "[2,6,7]") |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS("[1,3,5,7]", "[2,6,8]");
+-----+
| JSON_OVERLAPS("[1,3,5,7]", "[2,6,8]") |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

Partial matches are treated as no match, as shown here:

```
mysql> SELECT JSON_OVERLAPS('[1,2],[3,4],5]', '[1,[2,3],[4,5]]');
+-----+
| JSON_OVERLAPS('[1,2],[3,4],5]', '[1,[2,3],[4,5]]') |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

When comparing objects, the result is true if they have at least one key-value pair in common.

```
mysql> SELECT JSON_OVERLAPS('{ "a":1,"b":10,"d":10}', '{ "c":1,"e":10,"f":1,"d":10}');
+-----+
| JSON_OVERLAPS('{ "a":1,"b":10,"d":10}', '{ "c":1,"e":10,"f":1,"d":10}') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('{ "a":1,"b":10,"d":10}', '{ "a":5,"e":10,"f":1,"d":20}');
+-----+
| JSON_OVERLAPS('{ "a":1,"b":10,"d":10}', '{ "a":5,"e":10,"f":1,"d":20}') |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

If two scalars are used as the arguments to the function, `JSON_OVERLAPS()` performs a simple test for equality:

```
mysql> SELECT JSON_OVERLAPS('5', '5');
+-----+
| JSON_OVERLAPS('5', '5') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('5', '6');
+-----+
| JSON_OVERLAPS('5', '6') |
+-----+
| 0 |
+-----+
```

```
1 row in set (0.00 sec)
```

When comparing a scalar with an array, `JSON_OVERLAPS()` attempts to treat the scalar as an array element. In this example, the second argument `6` is interpreted as `[6]`, as shown here:

```
mysql> SELECT JSON_OVERLAPS('[4,5,6,7]', '6');
+-----+
| JSON_OVERLAPS('[4,5,6,7]', '6') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

The function does not perform type conversions:

```
mysql> SELECT JSON_OVERLAPS('[4,5,"6",7]', '6');
+-----+
| JSON_OVERLAPS('[4,5,"6",7]', '6') |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT JSON_OVERLAPS('[4,5,6,7]', '"6"');
+-----+
| JSON_OVERLAPS('[4,5,6,7]', '"6"') |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

`JSON_OVERLAPS()` was added in MySQL 8.0.17.

- `JSON_SEARCH(json_doc, one_or_all, search_str[, escape_char[, path] ...])`

Returns the path to the given string within a JSON document. Returns `NULL` if any of the `json_doc`, `search_str`, or `path` arguments are `NULL`; no `path` exists within the document; or `search_str` is not found. An error occurs if the `json_doc` argument is not a valid JSON document, any `path` argument is not a valid path expression, `one_or_all` is not `'one'` or `'all'`, or `escape_char` is not a constant expression.

The `one_or_all` argument affects the search as follows:

- `'one'`: The search terminates after the first match and returns one path string. It is undefined which match is considered first.
- `'all'`: The search returns all matching path strings such that no duplicate paths are included. If there are multiple strings, they are autowrapped as an array. The order of the array elements is undefined.

Within the `search_str` search string argument, the `%` and `_` characters work as for the `LIKE` operator: `%` matches any number of characters (including zero characters), and `_` matches exactly one character.

To specify a literal `%` or `_` character in the search string, precede it by the escape character. The default is `\` if the `escape_char` argument is missing or `NULL`. Otherwise, `escape_char` must be a constant that is empty or one character.

For more information about matching and escape character behavior, see the description of `LIKE` in [Section 12.8.1, “String Comparison Functions and Operators”](#). For escape character handling, a difference from the `LIKE` behavior is that the escape character for `JSON_SEARCH()` must evaluate to a constant at compile time, not just at execution time. For example, if `JSON_SEARCH()` is used

in a prepared statement and the *escape_char* argument is supplied using a *?* parameter, the parameter value might be constant at execution time, but is not at compile time.

```
mysql> SET @j = '["abc", [{"k": "10"}, "def"], {"x": "abc"}, {"y": "bcd"}]';

mysql> SELECT JSON_SEARCH(@j, 'one', 'abc');
+-----+
| JSON_SEARCH(@j, 'one', 'abc') |
+-----+
| "$[0]"                        |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', 'abc');
+-----+
| JSON_SEARCH(@j, 'all', 'abc') |
+-----+
| ["$[0]", "$[2].x"]           |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', 'ghi');
+-----+
| JSON_SEARCH(@j, 'all', 'ghi') |
+-----+
| NULL                          |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10');
+-----+
| JSON_SEARCH(@j, 'all', '10') |
+-----+
| "$[1][0].k"                  |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$');
+-----+
| JSON_SEARCH(@j, 'all', '10', NULL, '$') |
+-----+
| "$[1][0].k"                  |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[*]');
+-----+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[*]') |
+-----+
| "$[1][0].k"                  |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$**.k');
+-----+
| JSON_SEARCH(@j, 'all', '10', NULL, '$**.k') |
+-----+
| "$[1][0].k"                  |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[*][0].k');
+-----+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[*][0].k') |
+-----+
| "$[1][0].k"                  |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[1]');
+-----+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[1]') |
+-----+
| "$[1][0].k"                  |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '10', NULL, '$[1][0]');
+-----+
| JSON_SEARCH(@j, 'all', '10', NULL, '$[1][0]') |
+-----+
```

```

| "$[1][0].k" |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', 'abc', NULL, '$[2]');
+-----+
| JSON_SEARCH(@j, 'all', 'abc', NULL, '$[2]') |
+-----+
| "$[2].x" |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%a%');
+-----+
| JSON_SEARCH(@j, 'all', '%a%') |
+-----+
| ["$[0]", "$[2].x"] |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%');
+-----+
| JSON_SEARCH(@j, 'all', '%b%') |
+-----+
| ["$[0]", "$[2].x", "$[3].y"] |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%', NULL, '$[0]');
+-----+
| JSON_SEARCH(@j, 'all', '%b%', NULL, '$[0]') |
+-----+
| "$[0]" |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%', NULL, '$[2]');
+-----+
| JSON_SEARCH(@j, 'all', '%b%', NULL, '$[2]') |
+-----+
| "$[2].x" |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%', NULL, '$[1]');
+-----+
| JSON_SEARCH(@j, 'all', '%b%', NULL, '$[1]') |
+-----+
| NULL |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%', '', '$[1]');
+-----+
| JSON_SEARCH(@j, 'all', '%b%', '', '$[1]') |
+-----+
| NULL |
+-----+

mysql> SELECT JSON_SEARCH(@j, 'all', '%b%', '', '$[3]');
+-----+
| JSON_SEARCH(@j, 'all', '%b%', '', '$[3]') |
+-----+
| "$[3].y" |
+-----+
    
```

For more information about the JSON path syntax supported by MySQL, including rules governing the wildcard operators `*` and `**`, see [JSON Path Syntax](#).

- `JSON_VALUE(json_doc, path)`

Extracts a value from a JSON document at the path given in the specified document, and returns the extracted value, optionally converting it to a desired type. The complete syntax is shown here:

```

JSON_VALUE(json_doc, path [RETURNING type] [on_empty] [on_error])

on_empty:
{NULL | ERROR | DEFAULT value} ON EMPTY
    
```

```
on_error:
  {NULL | ERROR | DEFAULT value} ON ERROR
```

json_doc is a valid JSON document.

path is a JSON path pointing to a location in the document.

type is one of the following data types:

- `FLOAT`
- `DOUBLE`
- `DECIMAL`
- `SIGNED`
- `UNSIGNED`
- `DATE`
- `TIME`
- `DATETIME`
- `YEAR` (MySQL 8.0.22 and later)

`YEAR` values of one or two digits are not supported.

- `CHAR`
- `JSON`

The types just listed are the same as the (non-array) types supported by the `CAST()` function.

If not specified by a `RETURNING` clause, the `JSON_VALUE()` function's return type is `VARCHAR(512)`. When no character set is specified for the return type, `JSON_VALUE()` uses `utf8mb4` with the binary collation, which is case-sensitive; if `utf8mb4` is specified as the character

set for the result, the server uses the default collation for this character set, which is not case-sensitive.

When the data at the specified path consists of or resolves to a JSON null literal, the function returns SQL `NULL`.

`on_empty`, if specified, determines how `JSON_VALUE()` behaves when no data is found at the path given; this clause takes one of the following values:

- `NULL ON EMPTY`: The function returns `NULL`; this is the default `ON EMPTY` behavior.
- `DEFAULT value ON EMPTY`: the provided `value` is returned. The value's type must match that of the return type.
- `ERROR ON EMPTY`: The function throws an error.

If used, `on_error` takes one of the following values with the corresponding outcome when an error occurs, as listed here:

- `NULL ON ERROR`: `JSON_VALUE()` returns `NULL`; this is the default behavior if no `ON ERROR` clause is used.
- `DEFAULT value ON ERROR`: This is the value returned; its value must match that of the return type.
- `ERROR ON ERROR`: An error is thrown.

`ON EMPTY`, if used, must precede any `ON ERROR` clause. Specifying them in the wrong order results in a syntax error.

Error handling. In general, errors are handled by `JSON_VALUE()` as follows:

- All JSON input (document and path) is checked for validity. If any of it is not valid, an SQL error is thrown without triggering the `ON ERROR` clause.
- `ON ERROR` is triggered whenever any of the following events occur:
 - Attempting to extract an object or an array, such as that resulting from a path that resolves to multiple locations within the JSON document
 - Conversion errors, such as attempting to convert `'asdf'` to an `UNSIGNED` value
 - Truncation of values
- A conversion error always triggers a warning even if `NULL ON ERROR` or `DEFAULT ... ON ERROR` is specified.
- The `ON EMPTY` clause is triggered when the source JSON document (`expr`) contains no data at the specified location (`path`).

`JSON_VALUE()` was introduced in MySQL 8.0.21.

Examples. Two simple examples are shown here:

```
mysql> SELECT JSON_VALUE('{ "fname": "Joe", "lname": "Palmer"}', '$.fname');
+-----+
| JSON_VALUE('{ "fname": "Joe", "lname": "Palmer"}', '$.fname') |
+-----+
| Joe |
+-----+

mysql> SELECT JSON_VALUE('{ "item": "shoes", "price": "49.95"}', '$.price'
-> RETURNING DECIMAL(4,2)) AS price;
```

```
+-----+
| price |
+-----+
| 49.95 |
+-----+
```

The statement `SELECT JSON_VALUE(json_doc, path RETURNING type)` is equivalent to the following statement:

```
SELECT CAST(
  JSON_UNQUOTE( JSON_EXTRACT(json_doc, path) )
  AS type
);
```

`JSON_VALUE()` simplifies creating indexes on JSON columns by making it unnecessary in many cases to create a generated column and then an index on the generated column. You can do this when creating a table `t1` that has a `JSON` column by creating an index on an expression that uses `JSON_VALUE()` operating on that column (with a path that matches a value in that column), as shown here:

```
CREATE TABLE t1(
  j JSON,
  INDEX i1 ( (JSON_VALUE(j, '$.id' RETURNING UNSIGNED)) )
);
```

The following `EXPLAIN` output shows that a query against `t1` employing the index expression in the `WHERE` clause uses the index thus created:

```
mysql> EXPLAIN SELECT * FROM t1
->      WHERE JSON_VALUE(j, '$.id' RETURNING UNSIGNED) = 123\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: t1
   partitions: NULL
         type: ref
possible_keys: i1
          key: i1
        key_len: 9
           ref: const
            rows: 1
    filtered: 100.00
       Extra: NULL
```

This achieves much the same effect as creating a table `t2` with an index on a generated column (see [Indexing a Generated Column to Provide a JSON Column Index](#)), like this one:

```
CREATE TABLE t2 (
  j JSON,
  g INT GENERATED ALWAYS AS (j->"$.id"),
  INDEX i1 (j)
);
```

The `EXPLAIN` output for a query against this table, referencing the generated column, shows that the index is used in the same way as for the previous query against table `t1`:

```
mysql> EXPLAIN SELECT * FROM t2 WHERE g = 123\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: t2
   partitions: NULL
         type: ref
possible_keys: i1
          key: i1
        key_len: 5
           ref: const
            rows: 1
    filtered: 100.00
```

Extra: NULL

For information about using indexes on generated columns for indirect indexing of `JSON` columns, see [Indexing a Generated Column to Provide a JSON Column Index](#).

- `value MEMBER OF(json_array)`

Returns true (1) if `value` is an element of `json_array`, otherwise returns false (0). `value` must be a scalar or a JSON document; if it is a scalar, the operator attempts to treat it as an element of a JSON array.

Queries using `MEMBER OF()` on JSON columns of `InnoDB` tables in the `WHERE` clause can be optimized using multi-valued indexes. See [Multi-Valued Indexes](#), for detailed information and examples.

Simple scalars are treated as array values, as shown here:

```
mysql> SELECT 17 MEMBER OF('[23, "abc", 17, "ab", 10]');
+-----+
| 17 MEMBER OF('[23, "abc", 17, "ab", 10]') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT 'ab' MEMBER OF('[23, "abc", 17, "ab", 10]');
+-----+
| 'ab' MEMBER OF('[23, "abc", 17, "ab", 10]') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

Partial matches of array element values do not match:

```
mysql> SELECT 7 MEMBER OF('[23, "abc", 17, "ab", 10]');
+-----+
| 7 MEMBER OF('[23, "abc", 17, "ab", 10]') |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)

mysql> SELECT 'a' MEMBER OF('[23, "abc", 17, "ab", 10]');
+-----+
| 'a' MEMBER OF('[23, "abc", 17, "ab", 10]') |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

Conversions to and from string types are not performed:

```
mysql> SELECT
  -> 17 MEMBER OF('[23, "abc", "17", "ab", 10]'),
  -> "17" MEMBER OF('[23, "abc", 17, "ab", 10]')\G
***** 1. row *****
17 MEMBER OF('[23, "abc", "17", "ab", 10]'): 0
"17" MEMBER OF('[23, "abc", 17, "ab", 10]'): 0
1 row in set (0.00 sec)
```

To use this operator with a value which itself an array, it is necessary to cast it explicitly as a JSON array. You can do this with `CAST(... AS JSON)`:

```
mysql> SELECT CAST('[4,5]' AS JSON) MEMBER OF('[[3,4],[4,5]]');
+-----+
| CAST('[4,5]' AS JSON) MEMBER OF('[[3,4],[4,5]]') |
+-----+
```

```
| 1 |
+-----+
1 row in set (0.00 sec)
```

It is also possible to perform the necessary cast using the `JSON_ARRAY()` function, like this:

```
mysql> SELECT JSON_ARRAY(4,5) MEMBER OF('[[3,4],[4,5]]');
+-----+
| JSON_ARRAY(4,5) MEMBER OF('[[3,4],[4,5]]') |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

Any JSON objects used as values to be tested or which appear in the target array must be coerced to the correct type using `CAST(... AS JSON)` or `JSON_OBJECT()`. In addition, a target array containing JSON objects must itself be cast using `JSON_ARRAY`. This is demonstrated in the following sequence of statements:

```
mysql> SET @a = CAST('{\"a\":1}' AS JSON);
Query OK, 0 rows affected (0.00 sec)

mysql> SET @b = JSON_OBJECT("b", 2);
Query OK, 0 rows affected (0.00 sec)

mysql> SET @c = JSON_ARRAY(17, @b, "abc", @a, 23);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a MEMBER OF(@c), @b MEMBER OF(@c);
+-----+-----+
| @a MEMBER OF(@c) | @b MEMBER OF(@c) |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

The `MEMBER OF()` operator was added in MySQL 8.0.17.

12.18.4 Functions That Modify JSON Values

The functions in this section modify JSON values and return the result.

- `JSON_ARRAY_APPEND(json_doc, path, val[, path, val] ...)`

Appends values to the end of the indicated arrays within a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

If a path selects a scalar or object value, that value is autowrapped within an array and the new value is added to that array. Pairs for which the path does not identify any value in the JSON document are ignored.

```
mysql> SET @j = '['a', ['b', 'c'], 'd'];
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1]', 1);
+-----+
| JSON_ARRAY_APPEND(@j, '$[1]', 1) |
+-----+
| ['a', ['b', 'c', 1], 'd'] |
+-----+
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[0]', 2);
+-----+
| JSON_ARRAY_APPEND(@j, '$[0]', 2) |
+-----+
| [['a', 2], ['b', 'c'], 'd'] |
+-----+
```

```
mysql> SELECT JSON_ARRAY_APPEND(@j, '$[1][0]', 3);
+-----+
| JSON_ARRAY_APPEND(@j, '$[1][0]', 3) |
+-----+
| ["a", [{"b": 3}, "c"], "d"]          |
+-----+

mysql> SET @j = '{"a": 1, "b": [2, 3], "c": 4}';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$.b', 'x');
+-----+
| JSON_ARRAY_APPEND(@j, '$.b', 'x') |
+-----+
| {"a": 1, "b": [2, 3, "x"], "c": 4} |
+-----+

mysql> SELECT JSON_ARRAY_APPEND(@j, '$.c', 'y');
+-----+
| JSON_ARRAY_APPEND(@j, '$.c', 'y') |
+-----+
| {"a": 1, "b": [2, 3], "c": [4, "y"]} |
+-----+

mysql> SET @j = '{"a": 1}';
mysql> SELECT JSON_ARRAY_APPEND(@j, '$', 'z');
+-----+
| JSON_ARRAY_APPEND(@j, '$', 'z') |
+-----+
| [{"a": 1}, "z"]                  |
+-----+
```

In MySQL 5.7, this function was named `JSON_APPEND()`. That name is no longer supported in MySQL 8.0.

- `JSON_ARRAY_INSERT(json_doc, path, val[, path, val] ...)`

Updates a JSON document, inserting into an array within the document and returning the modified document. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard or does not end with an array element identifier.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

Pairs for which the path does not identify any array in the JSON document are ignored. If a path identifies an array element, the corresponding value is inserted at that element position, shifting any following values to the right. If a path identifies an array position past the end of an array, the value is inserted at the end of the array.

```
mysql> SET @j = '{"a", {"b": [1, 2]}, [3, 4]}';
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[1]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[1]', 'x') |
+-----+
| ["a", "x", {"b": [1, 2]}, [3, 4]] |
+-----+

mysql> SELECT JSON_ARRAY_INSERT(@j, '$[100]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[100]', 'x') |
+-----+
| ["a", {"b": [1, 2]}, [3, 4], "x"] |
+-----+

mysql> SELECT JSON_ARRAY_INSERT(@j, '$[1].b[0]', 'x');
+-----+
| JSON_ARRAY_INSERT(@j, '$[1].b[0]', 'x') |
+-----+
| ["a", {"b": ["x", 1, 2]}, [3, 4]] |
+-----+

mysql> SELECT JSON_ARRAY_INSERT(@j, '$[2][1]', 'y');
+-----+
| JSON_ARRAY_INSERT(@j, '$[2][1]', 'y') |
+-----+
```

```
+-----+
| ["a", {"b": [1, 2]}, [3, "y", 4]] |
+-----+
mysql> SELECT JSON_ARRAY_INSERT(@j, '$[0]', 'x', '$[2][1]', 'y');
+-----+
| JSON_ARRAY_INSERT(@j, '$[0]', 'x', '$[2][1]', 'y') |
+-----+
| ["x", "a", {"b": [1, 2]}, [3, 4]] |
+-----+
```

Earlier modifications affect the positions of the following elements in the array, so subsequent paths in the same `JSON_ARRAY_INSERT()` call should take this into account. In the final example, the second path inserts nothing because the path no longer matches anything after the first insert.

- `JSON_INSERT(json_doc, path, val[, path, val] ...)`

Inserts data into a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document is ignored and does not overwrite the existing document value. A path-value pair for a nonexisting path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexisting path in the document is ignored and has no effect.

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

```
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 1, "b": [2, 3], "c": "[true, false]"} |
+-----+
```

The third and final value listed in the result is a quoted string and not an array like the second one (which is not quoted in the output); no casting of values to the JSON type is performed. To insert the array as an array, you must perform such casts explicitly, as shown here:

```
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON));
+-----+
| JSON_INSERT(@j, '$.a', 10, '$.c', CAST('[true, false]' AS JSON)) |
+-----+
| {"a": 1, "b": [2, 3], "c": [true, false]} |
+-----+
1 row in set (0.00 sec)
```

- `JSON_MERGE(json_doc, json_doc[, json_doc] ...)`

Merges two or more JSON documents. Synonym for `JSON_MERGE_PRESERVE()`; deprecated in MySQL 8.0.3 and subject to removal in a future release.

```
mysql> SELECT JSON_MERGE('[1, 2]', '[true, false]');
+-----+
| JSON_MERGE('[1, 2]', '[true, false]') |
+-----+
```

```
+-----+
| [1, 2, true, false] |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1287
Message: 'JSON_MERGE' is deprecated and will be removed in a future release. \
Please use JSON_MERGE_PRESERVE/JSON_MERGE_PATCH instead
1 row in set (0.00 sec)
```

For additional examples, see the entry for [JSON_MERGE_PRESERVE\(\)](#).

- [JSON_MERGE_PATCH\(*json_doc*, *json_doc*\[, *json_doc*\] ...\)](#)

Performs an [RFC 7396](#) compliant merge of two or more JSON documents and returns the merged result, without preserving members having duplicate keys. Raises an error if at least one of the documents passed as arguments to this function is not valid.

Note

For an explanation and example of the differences between this function and [JSON_MERGE_PRESERVE\(\)](#), see [JSON_MERGE_PATCH\(\) compared with JSON_MERGE_PRESERVE\(\)](#).

[JSON_MERGE_PATCH\(\)](#) performs a merge as follows:

1. If the first argument is not an object, the result of the merge is the same as if an empty object had been merged with the second argument.
2. If the second argument is not an object, the result of the merge is the second argument.
3. If both arguments are objects, the result of the merge is an object with the following members:
 - All members of the first object which do not have a corresponding member with the same key in the second object.
 - All members of the second object which do not have a corresponding key in the first object, and whose value is not the JSON `null` literal.
 - All members with a key that exists in both the first and the second object, and whose value in the second object is not the JSON `null` literal. The values of these members are the results of recursively merging the value in the first object with the value in the second object.

For additional information, see [Normalization, Merging, and Autowrapping of JSON Values](#).

```
mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '[true, false]');
+-----+
| JSON_MERGE_PATCH('[1, 2]', '[true, false]') |
+-----+
| [true, false] |
+-----+

mysql> SELECT JSON_MERGE_PATCH('{\"name\": \"x\"}', '{\"id\": 47}');
+-----+
| JSON_MERGE_PATCH('{\"name\": \"x\"}', '{\"id\": 47}') |
+-----+
| {\"id\": 47, \"name\": \"x\"} |
+-----+

mysql> SELECT JSON_MERGE_PATCH('1', 'true');
+-----+
| JSON_MERGE_PATCH('1', 'true') |
+-----+
```

```
| true |
+-----+

mysql> SELECT JSON_MERGE_PATCH('[1, 2]', '{"id": 47}');
+-----+
| JSON_MERGE_PATCH('[1, 2]', '{"id": 47}') |
+-----+
| {"id": 47} |
+-----+

mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }',
>      '{ "a": 3, "c":4 }');
+-----+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }', '{ "a": 3, "c":4 }') |
+-----+
| {"a": 3, "b": 2, "c": 4} |
+-----+

mysql> SELECT JSON_MERGE_PATCH('{ "a": 1, "b":2 }', '{ "a": 3, "c":4 }',
>      '{ "a": 5, "d":6 }');
+-----+
| JSON_MERGE_PATCH('{ "a": 1, "b":2 }', '{ "a": 3, "c":4 }', '{ "a": 5, "d":6 }') |
+-----+
| {"a": 5, "b": 2, "c": 4, "d": 6} |
+-----+
```

You can use this function to remove a member by specifying `null` as the value of the same member in the second argument, as shown here:

```
mysql> SELECT JSON_MERGE_PATCH('{ "a":1, "b":2}', '{"b":null}');
+-----+
| JSON_MERGE_PATCH('{ "a":1, "b":2}', '{"b":null}') |
+-----+
| {"a": 1} |
+-----+
```

This example shows that the function operates in a recursive fashion; that is, values of members are not limited to scalars, but rather can themselves be JSON documents:

```
mysql> SELECT JSON_MERGE_PATCH('{ "a":{"x":1}}', '{"a":{"y":2}}');
+-----+
| JSON_MERGE_PATCH('{ "a":{"x":1}}', '{"a":{"y":2}}') |
+-----+
| {"a": { "x": 1, "y": 2}} |
+-----+
```

`JSON_MERGE_PATCH()` is supported in MySQL 8.0.3 and later.

JSON_MERGE_PATCH() compared with JSON_MERGE_PRESERVE(). The behavior of `JSON_MERGE_PATCH()` is the same as that of `JSON_MERGE_PRESERVE()`, with the following two exceptions:

- `JSON_MERGE_PATCH()` removes any member in the first object with a matching key in the second object, provided that the value associated with the key in the second object is not JSON `null`.
- If the second object has a member with a key matching a member in the first object, `JSON_MERGE_PATCH()` *replaces* the value in the first object with the value in the second object, whereas `JSON_MERGE_PRESERVE()` *appends* the second value to the first value.

This example compares the results of merging the same 3 JSON objects, each having a matching key "a", with each of these two functions:

```
mysql> SET @x = '{ "a": 1, "b": 2 }',
>      @y = '{ "a": 3, "c": 4 }',
>      @z = '{ "a": 5, "d": 6 }';

mysql> SELECT  JSON_MERGE_PATCH(@x, @y, @z)      AS Patch,
->      JSON_MERGE_PRESERVE(@x, @y, @z) AS Preserve\G
```

```
***** 1. row *****
Patch: { "a": 5, "b": 2, "c": 4, "d": 6 }
Preserve: { "a": [1, 3, 5], "b": 2, "c": 4, "d": 6 }
```

- `JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)`

Merges two or more JSON documents and returns the merged result. Returns `NULL` if any argument is `NULL`. An error occurs if any argument is not a valid JSON document.

Merging takes place according to the following rules. For additional information, see [Normalization, Merging, and Autowrapping of JSON Values](#).

- Adjacent arrays are merged to a single array.
- Adjacent objects are merged to a single object.
- A scalar value is autowrapped as an array and merged as an array.
- An adjacent array and object are merged by autowrapping the object as an array and merging the two arrays.

```
mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '[true, false]');
+-----+
| JSON_MERGE_PRESERVE('[1, 2]', '[true, false]') |
+-----+
| [1, 2, true, false] |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('{ "name": "x" }', '{ "id": 47 }');
+-----+
| JSON_MERGE_PRESERVE('{ "name": "x" }', '{ "id": 47 }') |
+-----+
| { "id": 47, "name": "x" } |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('1', 'true');
+-----+
| JSON_MERGE_PRESERVE('1', 'true') |
+-----+
| [1, true] |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('[1, 2]', '{ "id": 47 }');
+-----+
| JSON_MERGE_PRESERVE('[1, 2]', '{ "id": 47 }') |
+-----+
| [1, 2, { "id": 47 }] |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }',
>   '{ "a": 3, "c": 4 }');
+-----+
| JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }', '{ "a": 3, "c": 4 }') |
+-----+
| { "a": [1, 3], "b": 2, "c": 4 } |
+-----+

mysql> SELECT JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }', '{ "a": 3, "c": 4 }',
>   '{ "a": 5, "d": 6 }');
+-----+
| JSON_MERGE_PRESERVE('{ "a": 1, "b": 2 }', '{ "a": 3, "c": 4 }', '{ "a": 5, "d": 6 }') |
+-----+
| { "a": [1, 3, 5], "b": 2, "c": 4, "d": 6 } |
+-----+
```

This function was added in MySQL 8.0.3 as a synonym for `JSON_MERGE()`. The `JSON_MERGE()` function is now deprecated, and is subject to removal in a future release of MySQL.

This function is similar to but differs from `JSON_MERGE_PATCH()` in significant respects; see [JSON_MERGE_PATCH\(\) compared with JSON_MERGE_PRESERVE\(\)](#), for more information.

- `JSON_REMOVE(json_doc, path[, path] ...)`

Removes data from a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or is `$` or contains a `*` or `**` wildcard.

The `path` arguments are evaluated left to right. The document produced by evaluating one path becomes the new value against which the next path is evaluated.

It is not an error if the element to be removed does not exist in the document; in that case, the path does not affect the document.

```
mysql> SET @j = '["a", ["b", "c"], "d"]';
mysql> SELECT JSON_REMOVE(@j, '$[1]');
+-----+
| JSON_REMOVE(@j, '$[1]') |
+-----+
| ["a", "d"]              |
+-----+
```

- `JSON_REPLACE(json_doc, path, val[, path, val] ...)`

Replaces existing values in a JSON document and returns the result. Returns `NULL` if any argument is `NULL`. An error occurs if the `json_doc` argument is not a valid JSON document or any `path` argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexisting path in the document is ignored and has no effect.

In MySQL 8.0.4, the optimizer can perform a partial, in-place update of a `JSON` column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the `JSON_REPLACE()` function and meets the conditions outlined in [Partial Updates of JSON Values](#).

For a comparison of `JSON_INSERT()`, `JSON_REPLACE()`, and `JSON_SET()`, see the discussion of `JSON_SET()`.

```
mysql> SET @j = '{ "a": 1, "b": [2, 3] }';
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| { "a": 10, "b": [2, 3] }                             |
+-----+
```

- `JSON_SET(json_doc, path, val[, path, val] ...)`

Inserts or updates data in a JSON document and returns the result. Returns `NULL` if any argument is `NULL` or `path`, if given, does not locate an object. An error occurs if the `json_doc` argument is not

a valid JSON document or any [path](#) argument is not a valid path expression or contains a `*` or `**` wildcard.

The path-value pairs are evaluated left to right. The document produced by evaluating one pair becomes the new value against which the next pair is evaluated.

A path-value pair for an existing path in the document overwrites the existing document value with the new value. A path-value pair for a nonexistent path in the document adds the value to the document if the path identifies one of these types of values:

- A member not present in an existing object. The member is added to the object and associated with the new value.
- A position past the end of an existing array. The array is extended with the new value. If the existing value is not an array, it is autowrapped as an array, then extended with the new value.

Otherwise, a path-value pair for a nonexistent path in the document is ignored and has no effect.

In MySQL 8.0.4, the optimizer can perform a partial, in-place update of a [JSON](#) column instead of removing the old document and writing the new document in its entirety to the column. This optimization can be performed for an update statement that uses the [JSON_SET\(\)](#) function and meets the conditions outlined in [Partial Updates of JSON Values](#).

The [JSON_SET\(\)](#), [JSON_INSERT\(\)](#), and [JSON_REPLACE\(\)](#) functions are related:

- [JSON_SET\(\)](#) replaces existing values and adds nonexistent values.
- [JSON_INSERT\(\)](#) inserts values without replacing existing values.
- [JSON_REPLACE\(\)](#) replaces *only* existing values.

The following examples illustrate these differences, using one path that does exist in the document (`$.a`) and another that does not exist (`$.c`):

```
mysql> SET @j = '{ "a": 1, "b": [2, 3]}';
mysql> SELECT JSON_SET(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_SET(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 10, "b": [2, 3], "c": "[true, false]"}      |
+-----+
mysql> SELECT JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_INSERT(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 1, "b": [2, 3], "c": "[true, false]"}        |
+-----+
mysql> SELECT JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]');
+-----+
| JSON_REPLACE(@j, '$.a', 10, '$.c', '[true, false]') |
+-----+
| {"a": 10, "b": [2, 3]}                               |
+-----+
```

- [JSON_UNQUOTE\(json_val\)](#)

Unquotes JSON value and returns the result as a [utf8mb4](#) string. Returns [NULL](#) if the argument is [NULL](#). An error occurs if the value starts and ends with double quotes but is not a valid JSON string literal.

Within a string, certain sequences have special meaning unless the [NO_BACKSLASH_ESCAPES](#) SQL mode is enabled. Each of these sequences begins with a backslash (`\`), known as the *escape character*. MySQL recognizes the escape sequences shown in [Table 12.23, “JSON_UNQUOTE\(\) Special Character Escape Sequences”](#). For all other escape sequences, backslash is ignored. That

is, the escaped character is interpreted as if it was not escaped. For example, `\x` is just `x`. These sequences are case-sensitive. For example, `\b` is interpreted as a backspace, but `\B` is interpreted as `B`.

Table 12.23 JSON_UNQUOTE() Special Character Escape Sequences

Escape Sequence	Character Represented by Sequence
<code>\ "</code>	A double quote (") character
<code>\b</code>	A backspace character
<code>\f</code>	A formfeed character
<code>\n</code>	A newline (linefeed) character
<code>\r</code>	A carriage return character
<code>\t</code>	A tab character
<code>\\</code>	A backslash (\) character
<code>\uXXXX</code>	UTF-8 bytes for Unicode value <code>XXXX</code>

Two simple examples of the use of this function are shown here:

```
mysql> SET @j = '"abc"';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----+-----+
| @j      | JSON_UNQUOTE(@j) |
+-----+-----+
| "abc"   | abc               |
+-----+-----+
mysql> SET @j = '[1, 2, 3]';
mysql> SELECT @j, JSON_UNQUOTE(@j);
+-----+-----+
| @j      | JSON_UNQUOTE(@j) |
+-----+-----+
| [1, 2, 3] | [1, 2, 3]        |
+-----+-----+
```

The following set of examples shows how `JSON_UNQUOTE` handles escapes with `NO_BACKSLASH_ESCAPES` disabled and enabled:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+

mysql> SELECT JSON_UNQUOTE('"\\t\\u0032"');
+-----+
| JSON_UNQUOTE('"\\t\\u0032"') |
+-----+
| 2                             |
+-----+

mysql> SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';
mysql> SELECT JSON_UNQUOTE('"\\t\\u0032"');
+-----+
| JSON_UNQUOTE('"\\t\\u0032"') |
+-----+
| \\t\\u0032                    |
+-----+

mysql> SELECT JSON_UNQUOTE('"\\t\\u0032"');
+-----+
| JSON_UNQUOTE('"\\t\\u0032"') |
+-----+
| 2                             |
+-----+
```

12.18.5 Functions That Return JSON Value Attributes

The functions in this section return attributes of JSON values.

- `JSON_DEPTH(json_doc)`

Returns the maximum depth of a JSON document. Returns `NULL` if the argument is `NULL`. An error occurs if the argument is not a valid JSON document.

An empty array, empty object, or scalar value has depth 1. A nonempty array containing only elements of depth 1 or nonempty object containing only member values of depth 1 has depth 2. Otherwise, a JSON document has depth greater than 2.

```
mysql> SELECT JSON_DEPTH('{}'), JSON_DEPTH('[]'), JSON_DEPTH('true');
+-----+-----+-----+
| JSON_DEPTH('{}') | JSON_DEPTH('[]') | JSON_DEPTH('true') |
+-----+-----+-----+
| 1 | 1 | 1 |
+-----+-----+-----+
mysql> SELECT JSON_DEPTH('[10, 20]'), JSON_DEPTH('[[[], {}]]');
+-----+-----+
| JSON_DEPTH('[10, 20]') | JSON_DEPTH('[[[], {}]]') |
+-----+-----+
| 2 | 2 |
+-----+-----+
mysql> SELECT JSON_DEPTH('[10, {"a": 20}]');
+-----+
| JSON_DEPTH('[10, {"a": 20}]') |
+-----+
| 3 |
+-----+
```

- `JSON_LENGTH(json_doc[, path])`

Returns the length of a JSON document, or, if a *path* argument is given, the length of the value within the document identified by the path. Returns `NULL` if any argument is `NULL` or the *path* argument does not identify a value in the document. An error occurs if the *json_doc* argument is not a valid JSON document or the *path* argument is not a valid path expression or contains a `*` or `**` wildcard.

The length of a document is determined as follows:

- The length of a scalar is 1.
- The length of an array is the number of array elements.
- The length of an object is the number of object members.
- The length does not count the length of nested arrays or objects.

```
mysql> SELECT JSON_LENGTH('[1, 2, {"a": 3}]');
+-----+
| JSON_LENGTH('[1, 2, {"a": 3}]') |
+-----+
| 3 |
+-----+
mysql> SELECT JSON_LENGTH('{ "a": 1, "b": {"c": 30} }');
+-----+
| JSON_LENGTH('{ "a": 1, "b": {"c": 30} }') |
+-----+
| 2 |
+-----+
mysql> SELECT JSON_LENGTH('{ "a": 1, "b": {"c": 30} }', '$.b');
+-----+
| JSON_LENGTH('{ "a": 1, "b": {"c": 30} }', '$.b') |
+-----+
```

	1

- `JSON_TYPE(json_val)`

Returns a `utf8mb4` string indicating the type of a JSON value. This can be an object, an array, or a scalar type, as shown here:

```
mysql> SET @j = '{"a": [10, true]}';
mysql> SELECT JSON_TYPE(@j);
+-----+
| JSON_TYPE(@j) |
+-----+
| OBJECT        |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a')) |
+-----+
| ARRAY                                |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[0]')) |
+-----+
| INTEGER                                |
+-----+
mysql> SELECT JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]'));
+-----+
| JSON_TYPE(JSON_EXTRACT(@j, '$.a[1]')) |
+-----+
| BOOLEAN                                |
+-----+
```

`JSON_TYPE()` returns `NULL` if the argument is `NULL`:

```
mysql> SELECT JSON_TYPE(NULL);
+-----+
| JSON_TYPE(NULL) |
+-----+
| NULL            |
+-----+
```

An error occurs if the argument is not a valid JSON value:

```
mysql> SELECT JSON_TYPE(1);
ERROR 3146 (22032): Invalid data type for JSON data in argument 1
to function json_type; a JSON string or JSON type is required.
```

For a non-`NULL`, non-error result, the following list describes the possible `JSON_TYPE()` return values:

- Purely JSON types:
 - `OBJECT`: JSON objects
 - `ARRAY`: JSON arrays
 - `BOOLEAN`: The JSON true and false literals
 - `NULL`: The JSON null literal

- Numeric types:
 - **INTEGER**: MySQL **TINYINT**, **SMALLINT**, **MEDIUMINT** and **INT** and **BIGINT** scalars
 - **DOUBLE**: MySQL **DOUBLE** **FLOAT** scalars
 - **DECIMAL**: MySQL **DECIMAL** and **NUMERIC** scalars
- Temporal types:
 - **DATETIME**: MySQL **DATETIME** and **TIMESTAMP** scalars
 - **DATE**: MySQL **DATE** scalars
 - **TIME**: MySQL **TIME** scalars
- String types:
 - **STRING**: MySQL **utf8** character type scalars: **CHAR**, **VARCHAR**, **TEXT**, **ENUM**, and **SET**
- Binary types:
 - **BLOB**: MySQL binary type scalars including **BINARY**, **VARBINARY**, **BLOB**, and **BIT**
- All other types:
 - **OPAQUE** (raw bits)

• **JSON_VALID(val)**

Returns 0 or 1 to indicate whether a value is valid JSON. Returns **NULL** if the argument is **NULL**.

```
mysql> SELECT JSON_VALID('{\"a\": 1}');
+-----+
| JSON_VALID('{\"a\": 1}') |
+-----+
| 1 |
+-----+
mysql> SELECT JSON_VALID('hello'), JSON_VALID('\"hello\"');
+-----+-----+
| JSON_VALID('hello') | JSON_VALID('\"hello\"') |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

12.18.6 JSON Table Functions

This section contains information about JSON functions that convert JSON data to tabular data. In MySQL 8.0.4 and later, one such function—**JSON_TABLE()**—is supported.

- **JSON_TABLE(expr, path COLUMNS (column_list) [AS] alias)**

Extracts data from a JSON document and returns it as a relational table having the specified columns. The complete syntax for this function is shown here:

```
JSON_TABLE(
  expr,
  path COLUMNS (column_list)
) [AS] alias

column_list:
  column[, column][, ...]

column:
  name FOR ORDINALITY
```

```

| name type PATH string path [on_empty] [on_error]
| name type EXISTS PATH string path
| NESTED [PATH] path COLUMNS (column_list)

on_empty:
{NULL | DEFAULT json_string | ERROR} ON EMPTY

on_error:
{NULL | DEFAULT json_string | ERROR} ON ERROR

```

expr: This is an expression that returns JSON data. This can be a constant (`'{"a":1}'`), a column (`t1.json_data`, given table `t1` specified prior to `JSON_TABLE()` in the `FROM` clause), or a function call (`JSON_EXTRACT(t1.json_data, '$.post.comments')`).

path: A JSON path expression, which is applied to the data source. We refer to the JSON value matching the path as the *row source*; this is used to generate a row of relational data. The `COLUMNS` clause evaluates the row source, finds specific JSON values within the row source, and returns those JSON values as SQL values in individual columns of a row of relational data.

The *alias* is required. The usual rules for table aliases apply (see [Section 9.2, “Schema Object Names”](#)).

`JSON_TABLE()` supports four types of columns, described in the following list:

1. *name* FOR ORDINALITY: This type enumerates rows in the `COLUMNS` clause; the column named *name* is a counter whose type is `UNSIGNED INT`, and whose initial value is 1. This is equivalent to specifying a column as `AUTO_INCREMENT` in a `CREATE TABLE` statement, and can be used to distinguish parent rows with the same value for multiple rows generated by a `NESTED [PATH]` clause.
2. *name* type PATH string path [on_empty] [on_error]: Columns of this type are used to extract values specified by *string_path*. *type* is a MySQL scalar data type (that is, it cannot be an object or array). `JSON_TABLE()` extracts data as JSON then coerces it to the column type, using the regular automatic type conversion applying to JSON data in MySQL. A missing value triggers the *on_empty* clause. Saving an object or array triggers the optional *on error* clause; this also occurs when an error takes place during coercion from the value saved as JSON to the table column, such as trying to save the string `'asd'` to an integer column.
3. *name* type EXISTS PATH path: This column returns 1 if any data is present at the location specified by *path*, and 0 otherwise. *type* can be any valid MySQL data type, but should normally be specified as some variety of `INT`.
4. NESTED [PATH] path COLUMNS (column_list): This flattens nested objects or arrays in JSON data into a single row along with the JSON values from the parent object or array. Using multiple `PATH` options allows projection of JSON values from multiple levels of nesting into a single row.

The *path* is relative to the parent path row path of `JSON_TABLE()`, or the path of the parent `NESTED [PATH]` clause in the event of nested paths.

on empty, if specified, determines what `JSON_TABLE()` does in the event that data is missing (depending on type). This clause is also triggered on a column in a `NESTED PATH` clause when the latter has no match and a `NULL` complemented row is produced for it. *on empty* takes one of the following values:

- `NULL ON EMPTY`: The column is set to `NULL`; this is the default behavior.
- `DEFAULT json_string ON EMPTY`: the provided *json_string* is parsed as JSON, as long as it is valid, and stored instead of the missing value. Column type rules also apply to the default value.

- `ERROR ON EMPTY`: An error is thrown.

If used, `on_error` takes one of the following values with the corresponding result as shown here:

- `NULL ON ERROR`: The column is set to `NULL`; this is the default behavior.
- `DEFAULT json_string ON ERROR`: The `json_string` is parsed as JSON (provided that it is valid) and stored instead of the object or array.
- `ERROR ON ERROR`: An error is thrown.

Prior to MySQL 8.0.20, a warning was thrown if a type conversion error occurred with `NULL ON ERROR` or `DEFAULT ... ON ERROR` was specified or implied. In MySQL 8.0.20 and later, this is no longer the case. (Bug #30628330)

Previously, it was possible to specify `ON EMPTY` and `ON ERROR` clauses in either order. This runs counter to the SQL standard, which stipulates that `ON EMPTY`, if specified, must precede any `ON ERROR` clause. For this reason, beginning with MySQL 8.0.20, specifying `ON ERROR` before `ON EMPTY` is deprecated; trying to do so causes the server to issue a warning. Support for the nonstandard syntax will be removed in a future version of MySQL.

When a value saved to a column is truncated, such as saving 3.14159 in a `DECIMAL(10,1)` column, a warning is issued independently of any `ON ERROR` option. When multiple values are truncated in a single statement, the warning is issued only once.

Prior to MySQL 8.0.21, when the expression and path passed to this function resolved to JSON null, `JSON_TABLE()` raised an error. In MySQL 8.0.21 and later, it returns SQL `NULL` in such cases, in accordance with the SQL standard, as shown here (Bug #31345503, Bug #99557):

```
mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     '[{"c1": null}]',
->     '$[*]' COLUMNS( c1 INT PATH '$.c1' ERROR ON ERROR )
->   ) as jt;
+-----+
| c1 |
+-----+
| NULL |
+-----+
1 row in set (0.00 sec)
```

The following query demonstrates the use of `ON EMPTY` and `ON ERROR`. The row corresponding to `{"b":1}` is empty for the path `"$.a"`, and attempting to save `[1,2]` as a scalar produces an error; these rows are highlighted in the output shown.

```
mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     '[{"a":"3"}, {"a":2}, {"b":1}, {"a":0}, {"a":[1,2]}]',
->     "$[*]"
->     COLUMNS(
->       rowid FOR ORDINALITY,
->       ac VARCHAR(100) PATH "$.a" DEFAULT '111' ON EMPTY DEFAULT '999' ON ERROR,
->       aj JSON PATH "$.a" DEFAULT '{"x": 333}' ON EMPTY,
->       bx INT EXISTS PATH "$.b"
->     )
->   ) AS tt;
+-----+-----+-----+-----+
| rowid | ac   | aj      | bx |
+-----+-----+-----+-----+
| 1     | 3    | "3"     | 0  |
| 2     | 2    | 2        | 0  |
| 3     | 111  | {"x": 333} | 1  |
```

```

+-----+-----+-----+-----+
|      4 | 0      | 0      |      0 |
|      5 | 999    | [1, 2]  |      0 |
+-----+-----+-----+-----+
5 rows in set (0.00 sec)

```

Column names are subject to the usual rules and limitations governing table column names. See [Section 9.2, “Schema Object Names”](#).

All JSON and JSON path expressions are checked for validity; an invalid expression of either type causes an error.

Each match for the *path* preceding the *COLUMNS* keyword maps to an individual row in the result table. For example, the following query gives the result shown here:

```

mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     ' [{"x":2,"y":8},{ "x": "3", "y": "7"}, {"x": "4", "y": 6}] ',
->     "$[*]" COLUMNS(
->       xval VARCHAR(100) PATH "$.x",
->       yval VARCHAR(100) PATH "$.y"
->     )
->   ) AS jt1;

```

xval	yval
2	8
3	7
4	6

The expression `"$[*]"` matches each element of the array. You can filter the rows in the result by modifying the path. For example, using `"$[1]"` limits extraction to the second element of the JSON array used as the source, as shown here:

```

mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     ' [{"x":2,"y":8},{ "x": "3", "y": "7"}, {"x": "4", "y": 6}] ',
->     "$[1]" COLUMNS(
->       xval VARCHAR(100) PATH "$.x",
->       yval VARCHAR(100) PATH "$.y"
->     )
->   ) AS jt1;

```

xval	yval
3	7

Within a column definition, `"$"` passes the entire match to the column; `"$.x"` and `"$.y"` pass only the values corresponding to the keys *x* and *y*, respectively, within that match. For more information, see [JSON Path Syntax](#).

NESTED PATH (or simply **NESTED**; **PATH** is optional) produces a set of records for each match in the **COLUMNS** clause to which it belongs. If there is no match, all columns of the nested path are set to **NULL**. This implements an outer join between the topmost clause and **NESTED [PATH]**. An inner join can be emulated by applying a suitable condition in the **WHERE** clause, as shown here:

```

mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     '[ {"a": 1, "b": [11,111]}, {"a": 2, "b": [22,222]}, {"a":3}] ',
->     '$[*]' COLUMNS(
->       a INT PATH '$.a',
->       NESTED PATH '$.b[*]' COLUMNS (b INT PATH '$')

```

```

->      )
->    ) AS jt
-> WHERE b IS NOT NULL;

```

a	b
1	11
1	111
2	22
2	222

Sibling nested paths—that is, two or more instances of `NESTED [PATH]` in the same `COLUMNS` clause—are processed one after another, one at a time. While one nested path is producing records, columns of any sibling nested path expressions are set to `NULL`. This means that the total number of records for a single match within a single containing `COLUMNS` clause is the sum and not the product of all records produced by `NESTED [PATH]` modifiers, as shown here:

```

mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     '["a": 1, "b": [11,111]], {"a": 2, "b": [22,222]}' ,
->     '$[*]' COLUMNS(
->       a INT PATH '$.a',
->       NESTED PATH '$.b[*]' COLUMNS (b1 INT PATH '$'),
->       NESTED PATH '$.b[*]' COLUMNS (b2 INT PATH '$')
->     )
-> ) AS jt;

```

a	b1	b2
1	11	NULL
1	111	NULL
1	NULL	11
1	NULL	111
2	22	NULL
2	222	NULL
2	NULL	22
2	NULL	222

A `FOR ORDINALITY` column enumerates records produced by the `COLUMNS` clause, and can be used to distinguish parent records of a nested path, especially if values in parent records are the same, as can be seen here:

```

mysql> SELECT *
-> FROM
->   JSON_TABLE(
->     '["a": "a_val",
->      "b": [{"c": "c_val", "l": [1,2]}]},
->     {"a": "a_val",
->      "b": [{"c": "c_val", "l": [11]}, {"c": "c_val", "l": [22]}]}',
->     '$[*]' COLUMNS(
->       top_ord FOR ORDINALITY,
->       apath VARCHAR(10) PATH '$.a',
->       NESTED PATH '$.b[*]' COLUMNS (
->         bpath VARCHAR(10) PATH '$.c',
->         ord FOR ORDINALITY,
->         NESTED PATH '$.l[*]' COLUMNS (lpath varchar(10) PATH '$')
->       )
->     )
-> ) as jt;

```

top_ord	apath	bpath	ord	lpath
1	a_val	c_val	1	1
1	a_val	c_val	1	2

2	a_val	c_val	1	11
2	a_val	c_val	2	22

The source document contains an array of two elements; each of these elements produces two rows. The values of `apath` and `bpath` are the same over the entire result set; this means that they cannot be used to determine whether `lpath` values came from the same or different parents. The value of the `ord` column remains the same as the set of records having `top_ord` equal to 1, so these two values are from a single object. The remaining two values are from different objects, since they have different values in the `ord` column.

12.18.7 JSON Schema Validation Functions

Beginning with MySQL 8.0.17, MySQL supports validation of JSON documents against JSON schemas conforming to [Draft 4 of the JSON Schema specification](#). This can be done using either of the functions detailed in this section, both of which take two arguments, a JSON schema, and a JSON document which is validated against the schema. `JSON_SCHEMA_VALID()` returns true if the document validates against the schema, and false if it does not; `JSON_SCHEMA_VALIDATION_REPORT()` provides a report in JSON format on the validation.

Both functions handle null or invalid input as follows:

- If at least one of the arguments is `NULL`, the function returns `NULL`.
- If at least one of the arguments is not valid JSON, the function raises an error (`ER_INVALID_TYPE_FOR_JSON`)
- In addition, if the schema is not a valid JSON object, the function returns `ER_INVALID_JSON_TYPE`.

MySQL supports the `required` attribute in JSON schemas to enforce the inclusion of required properties (see the examples in the function descriptions).

MySQL supports the `id`, `$schema`, `description`, and `type` attributes in JSON schemas but does not require any of these.

MySQL does not support external resources in JSON schemas; using the `$ref` keyword causes `JSON_SCHEMA_VALID()` to fail with `ER_NOT_SUPPORTED_YET`.

Note

MySQL supports regular expression patterns in JSON schema, which supports but silently ignores invalid patterns (see the description of `JSON_SCHEMA_VALID()` for an example).

These functions are described in detail in the following list:

- `JSON_SCHEMA_VALID(schema, document)`

Validates a JSON *document* against a JSON *schema*. Both *schema* and *document* are required. The schema must be a valid JSON object; the document must be a valid JSON document. Provided that these conditions are met: If the document validates against the schema, the function returns true (1); otherwise, it returns false (0).

In this example, we set a user variable `@schema` to the value of a JSON schema for geographical coordinates, and another one `@document` to the value of a JSON document containing one such coordinate. We then verify that `@document` validates according to `@schema` by using them as the arguments to `JSON_SCHEMA_VALID()`:

```
mysql> SET @schema = '{
  >   "id": "http://json-schema.org/geo",
  >   "$schema": "http://json-schema.org/draft-04/schema#",
  >   "description": "A geographical coordinate",
  >   "type": "object",
  >   "properties": {
```

```

'>   "latitude": {
'>     "type": "number",
'>     "minimum": -90,
'>     "maximum": 90
'>   },
'>   "longitude": {
'>     "type": "number",
'>     "minimum": -180,
'>     "maximum": 180
'>   }
'> },
'> "required": ["latitude", "longitude"]
'> }';
Query OK, 0 rows affected (0.01 sec)

mysql> SET @document = '{
'>   "latitude": 63.444697,
'>   "longitude": 10.445118
'> }';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+-----+
| JSON_SCHEMA_VALID(@schema, @document) |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

```

Since `@schema` contains the `required` attribute, we can set `@document` to a value that is otherwise valid but does not contain the required properties, then test it against `@schema`, like this:

```

mysql> SET @document = '{}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+-----+
| JSON_SCHEMA_VALID(@schema, @document) |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)

```

If we now set the value of `@schema` to the same JSON schema but without the `required` attribute, `@document` validates because it is a valid JSON object, even though it contains no properties, as shown here:

```

mysql> SET @schema = '{
'>   "id": "http://json-schema.org/geo",
'>   "$schema": "http://json-schema.org/draft-04/schema#",
'>   "description": "A geographical coordinate",
'>   "type": "object",
'>   "properties": {
'>     "latitude": {
'>       "type": "number",
'>       "minimum": -90,
'>       "maximum": 90
'>     },
'>     "longitude": {
'>       "type": "number",
'>       "minimum": -180,
'>       "maximum": 180
'>     }
'>   }
'> }';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALID(@schema, @document);
+-----+
| JSON_SCHEMA_VALID(@schema, @document) |
+-----+

```

```
+-----+
|                                             1 |
+-----+
1 row in set (0.00 sec)
```

JSON_SCHEMA_VALID() and CHECK constraints. `JSON_SCHEMA_VALID()` can also be used to enforce `CHECK` constraints.

Consider the table `geo` created as shown here, with a JSON column `coordinate` representing a point of latitude and longitude on a map, governed by the JSON schema used as an argument in a `JSON_SCHEMA_VALID()` call which is passed as the expression for a `CHECK` constraint on this table:

```
mysql> CREATE TABLE geo (
->     coordinate JSON,
->     CHECK(
->         JSON_SCHEMA_VALID(
->             '{
->                 "type":"object",
->                 "properties":{
->                     "latitude":{"type":"number", "minimum":-90, "maximum":90},
->                     "longitude":{"type":"number", "minimum":-180, "maximum":180}
->                 },
->                 "required": ["latitude", "longitude"]
->             },
->             coordinate
->         )
-> );
Query OK, 0 rows affected (0.45 sec)
```

Note

Because a MySQL `CHECK` constraint cannot contain references to variables, you must pass the JSON schema to `JSON_SCHEMA_VALID()` inline when using it to specify such a constraint for a table.

We assign JSON values representing coordinates to three variables, as shown here:

```
mysql> SET @point1 = '{"latitude":59, "longitude":18}';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @point2 = '{"latitude":91, "longitude":0}';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @point3 = '{"longitude":120}';
Query OK, 0 rows affected (0.00 sec)
```

The first of these values is valid, as can be seen in the following `INSERT` statement:

```
mysql> INSERT INTO geo VALUES(@point1);
Query OK, 1 row affected (0.05 sec)
```

The second JSON value is invalid and so fails the constraint, as shown here:

```
mysql> INSERT INTO geo VALUES(@point2);
ERROR 3819 (HY000): Check constraint 'geo_chk_1' is violated.
```

In MySQL 8.0.19 and later, you can obtain precise information about the nature of the failure—in this case, that the `latitude` value exceeds the maximum defined in the schema—by issuing a `SHOW WARNINGS` statement:

```
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Error
Code: 3934
Message: The JSON document location '#/latitude' failed requirement 'maximum' at
```

```

JSON Schema location '#/properties/latitude'.
***** 2. row *****
Level: Error
Code: 3819
Message: Check constraint 'geo_chk_1' is violated.
2 rows in set (0.00 sec)

```

The third coordinate value defined above is also invalid, since it is missing the required `latitude` property. As before, you can see this by attempting to insert the value into the `geo` table, then issuing `SHOW WARNINGS` afterwards:

```

mysql> INSERT INTO geo VALUES(@point3);
ERROR 3819 (HY000): Check constraint 'geo_chk_1' is violated.
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Error
Code: 3934
Message: The JSON document location '#' failed requirement 'required' at JSON
Schema location '#'.
***** 2. row *****
Level: Error
Code: 3819
Message: Check constraint 'geo_chk_1' is violated.
2 rows in set (0.00 sec)

```

See [Section 13.1.20.6, “CHECK Constraints”](#), for more information.

JSON Schema has support for specifying regular expression patterns for strings, but the implementation used by MySQL silently ignores invalid patterns. This means that `JSON_SCHEMA_VALID()` can return true even when a regular expression pattern is invalid, as shown here:

```

mysql> SELECT JSON_SCHEMA_VALID('{ "type": "string", "pattern": "(", "abc" }');
+-----+
| JSON_SCHEMA_VALID('{ "type": "string", "pattern": "(", "abc" }') |
+-----+
|                                                                    1 |
+-----+
1 row in set (0.04 sec)

```

- `JSON_SCHEMA_VALIDATION_REPORT(schema, document)`

Validates a JSON *document* against a JSON *schema*. Both *schema* and *document* are required. As with `JSON_VALID_SCHEMA()`, the schema must be a valid JSON object, and the document must be a valid JSON document. Provided that these conditions are met, the function returns a report, as a JSON document, on the outcome of the validation. If the JSON document is considered valid according to the JSON Schema, the function returns a JSON object with one property `valid` having the value `"true"`. If the JSON document fails validation, the function returns a JSON object which includes the properties listed here:

- `valid`: Always `"false"` for a failed schema validation
- `reason`: A human-readable string containing the reason for the failure
- `schema-location`: A JSON pointer URI fragment identifier indicating where in the JSON schema the validation failed (see Note following this list)
- `document-location`: A JSON pointer URI fragment identifier indicating where in the JSON document the validation failed (see Note following this list)

- `schema-failed-keyword`: A string containing the name of the keyword or property in the JSON schema that was violated

Note

JSON pointer URI fragment identifiers are defined in [RFC 6901 - JavaScript Object Notation \(JSON\) Pointer](#). (These are *not* the same as the JSON path notation used by `JSON_EXTRACT()` and other MySQL JSON functions.) In this notation, `#` represents the entire document, and `#/myprop` represents the portion of the document included in the top-level property named `myprop`. See the specification just cited and the examples shown later in this section for more information.

In this example, we set a user variable `@schema` to the value of a JSON schema for geographical coordinates, and another one `@document` to the value of a JSON document containing one such coordinate. We then verify that `@document` validates according to `@schema` by using them as the arguments to `JSON_SCHEMA_VALIDATION_REPORT()`:

```
mysql> SET @schema = '{
  > "id": "http://json-schema.org/geo",
  > "$schema": "http://json-schema.org/draft-04/schema#",
  > "description": "A geographical coordinate",
  > "type": "object",
  > "properties": {
  >   "latitude": {
  >     "type": "number",
  >     "minimum": -90,
  >     "maximum": 90
  >   },
  >   "longitude": {
  >     "type": "number",
  >     "minimum": -180,
  >     "maximum": 180
  >   }
  > },
  > "required": ["latitude", "longitude"]
  > }';

Query OK, 0 rows affected (0.01 sec)

mysql> SET @document = '{
  > "latitude": 63.444697,
  > "longitude": 10.445118
  > }';

Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document);
+-----+
| JSON_SCHEMA_VALIDATION_REPORT(@schema, @document) |
+-----+
| {"valid": true}                                     |
+-----+
1 row in set (0.00 sec)
```

Now we set `@document` such that it specifies an illegal value for one of its properties, like this:

```
mysql> SET @document = '{
  > "latitude": 63.444697,
  > "longitude": 310.445118
  > }';
```

Validation of `@document` now fails when tested with `JSON_SCHEMA_VALIDATION_REPORT()`. The output from the function call contains detailed information about the failure (with the function wrapped by `JSON_PRETTY()` to provide better formatting), as shown here:

```
mysql> SELECT JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document))\G
***** 1. row *****
```

```

JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document)): {
  "valid": false,
  "reason": "The JSON document location '#/longitude' failed requirement 'maximum' at JSON Schema location '#/properties/longitude'",
  "schema-location": "#/properties/longitude",
  "document-location": "#/longitude",
  "schema-failed-keyword": "maximum"
}
1 row in set (0.00 sec)

```

Since `@schema` contains the `required` attribute, we can set `@document` to a value that is otherwise valid but does not contain the required properties, then test it against `@schema`. The output of `JSON_SCHEMA_VALIDATION_REPORT()` shows that validation fails due to lack of a required element, like this:

```

mysql> SET @document = '{}';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document))\G
***** 1. row *****
JSON_PRETTY(JSON_SCHEMA_VALIDATION_REPORT(@schema, @document)): {
  "valid": false,
  "reason": "The JSON document location '#' failed requirement 'required' at JSON Schema location '#'",
  "schema-location": "#",
  "document-location": "#",
  "schema-failed-keyword": "required"
}
1 row in set (0.00 sec)

```

If we now set the value of `@schema` to the same JSON schema but without the `required` attribute, `@document` validates because it is a valid JSON object, even though it contains no properties, as shown here:

```

mysql> SET @schema = '{
  > "id": "http://json-schema.org/geo",
  > "$schema": "http://json-schema.org/draft-04/schema#",
  > "description": "A geographical coordinate",
  > "type": "object",
  > "properties": {
  >   "latitude": {
  >     "type": "number",
  >     "minimum": -90,
  >     "maximum": 90
  >   },
  >   "longitude": {
  >     "type": "number",
  >     "minimum": -180,
  >     "maximum": 180
  >   }
  > }
  > }';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT JSON_SCHEMA_VALIDATION_REPORT(@schema, @document);
+-----+
| JSON_SCHEMA_VALIDATION_REPORT(@schema, @document) |
+-----+
| {"valid": true}                                     |
+-----+
1 row in set (0.00 sec)

```

12.18.8 JSON Utility Functions

This section documents utility functions that act on JSON values, or strings that can be parsed as JSON values. `JSON_PRETTY()` prints out a JSON value in a format that is easy to read. `JSON_STORAGE_SIZE()` and `JSON_STORAGE_FREE()` show, respectively, the amount of storage space used by a given JSON value and the amount of space remaining in a `JSON` column following a partial update.

- `JSON_PRETTY(json_val)`

Provides pretty-printing of JSON values similar to that implemented in PHP and by other languages and database systems. The value supplied must be a JSON value or a valid string representation of a JSON value. Extraneous whitespaces and newlines present in this value have no effect on the output. For a `NULL` value, the function returns `NULL`. If the value is not a JSON document, or if it cannot be parsed as one, the function fails with an error.

Formatting of the output from this function adheres to the following rules:

- Each array element or object member appears on a separate line, indented by one additional level as compared to its parent.
- Each level of indentation adds two leading spaces.
- A comma separating individual array elements or object members is printed before the newline that separates the two elements or members.
- The key and the value of an object member are separated by a colon followed by a space (`' : '`).
- An empty object or array is printed on a single line. No space is printed between the opening and closing brace.
- Special characters in string scalars and key names are escaped employing the same rules used by the `JSON_QUOTE()` function.

```
mysql> SELECT JSON_PRETTY('123'); # scalar
+-----+
| JSON_PRETTY('123') |
+-----+
| 123                |
+-----+

mysql> SELECT JSON_PRETTY("[1,3,5]"); # array
+-----+
| JSON_PRETTY("[1,3,5]") |
+-----+
| [
|   1,
|   3,
|   5
| ] |
+-----+

mysql> SELECT JSON_PRETTY('{ "a": "10", "b": "15", "x": "25" }'); # object
+-----+
| JSON_PRETTY(' { "a": "10", "b": "15", "x": "25" } ') |
+-----+
| {
|   "a": "10",
|   "b": "15",
|   "x": "25"
| } |
+-----+

mysql> SELECT JSON_PRETTY('["a",1,{"key1":
  > "value1"},"5", "77" ,
  > {"key2":["value3","valueX",
  > "valueY"]},"j", "2"   ]')\G # nested arrays and objects
***** 1. row *****
JSON_PRETTY('["a",1,{"key1":
      "value1"},"5", "77" ,
      {"key2":["value3","valueX",
      "valueY"]},"j", "2"   ]'): [
  "a",
  1,
  {
    "key1": "value1"
```

```

    },
    "5",
    "77",
    {
      "key2": [
        "value3",
        "valuex",
        "valuey"
      ]
    },
    "j",
    "2"
  ]

```

- `JSON_STORAGE_FREE(json_val)`

For a `JSON` column value, this function shows how much storage space was freed in its binary representation after it was updated in place using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The argument can also be a valid JSON document or a string which can be parsed as one—either as a literal value or as the value of a user variable—in which case the function returns 0. It returns a positive, nonzero value if the argument is a `JSON` column value which has been updated as described previously, such that its binary representation takes up less space than it did prior to the update. For a `JSON` column which has been updated such that its binary representation is the same as or larger than before, or if the update was not able to take advantage of a partial update, it returns 0; it returns `NULL` if the argument is `NULL`.

If `json_val` is not `NULL`, and neither is a valid JSON document nor can be successfully parsed as one, an error results.

In this example, we create a table containing a `JSON` column, then insert a row containing a JSON object:

```

mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.38 sec)

mysql> INSERT INTO jtable VALUES
->      ('{"a": 10, "b": "wxyz", "c": "[true, false]"}');
Query OK, 1 row affected (0.04 sec)

mysql> SELECT * FROM jtable;
+-----+
| jcol                                     |
+-----+
| {"a": 10, "b": "wxyz", "c": "[true, false]"} |
+-----+
1 row in set (0.00 sec)

```

Now we update the column value using `JSON_SET()` such that a partial update can be performed; in this case, we replace the value pointed to by the `c` key (the array `[true, false]`) with one that takes up less space (the integer `1`):

```

mysql> UPDATE jtable
->      SET jcol = JSON_SET(jcol, "$.a", 10, "$.b", "wxyz", "$.c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT * FROM jtable;
+-----+
| jcol                                     |
+-----+
| {"a": 10, "b": "wxyz", "c": 1} |
+-----+
1 row in set (0.00 sec)

mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-----+
| JSON_STORAGE_FREE(jcol) |
+-----+

```

```
| 14 |
+-----+
1 row in set (0.00 sec)
```

The effects of successive partial updates on this free space are cumulative, as shown in this example using `JSON_SET()` to reduce the space taken up by the value having key `b` (and making no other changes):

```
mysql> UPDATE jtable
-> SET jcol = JSON_SET(jcol, "$.a", 10, "$.b", "wx", "$.c", 1);
Query OK, 1 row affected (0.03 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-----+
| JSON_STORAGE_FREE(jcol) |
+-----+
| 16 |
+-----+
1 row in set (0.00 sec)
```

Updating the column without using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()` means that the optimizer cannot perform the update in place; in this case, `JSON_STORAGE_FREE()` returns 0, as shown here:

```
mysql> UPDATE jtable SET jcol = '{"a": 10, "b": 1}';
Query OK, 1 row affected (0.05 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT JSON_STORAGE_FREE(jcol) FROM jtable;
+-----+
| JSON_STORAGE_FREE(jcol) |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

Partial updates of JSON documents can be performed only on column values. For a user variable that stores a JSON value, the value is always completely replaced, even when the update is performed using `JSON_SET()`:

```
mysql> SET @j = '{"a": 10, "b": "wxyz", "c": "[true, false]"}';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$.a', 10, '$.b', 'wxyz', '$.c', '1');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_FREE(@j) AS Free;
+-----+-----+
| @j | Free |
+-----+-----+
| {"a": 10, "b": "wxyz", "c": "1"} | 0 |
+-----+-----+
1 row in set (0.00 sec)
```

For a JSON literal, this function always returns 0:

```
mysql> SELECT JSON_STORAGE_FREE('{"a": 10, "b": "wxyz", "c": "1"}') AS Free;
+-----+
| Free |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

- `JSON_STORAGE_SIZE(json_val)`

This function returns the number of bytes used to store the binary representation of a JSON document. When the argument is a `JSON` column, this is the space used to store the JSON

document as it was inserted into the column, prior to any partial updates that may have been performed on it afterwards. `json_val` must be a valid JSON document or a string which can be parsed as one. In the case where it is string, the function returns the amount of storage space in the JSON binary representation that is created by parsing the string as JSON and converting it to binary. It returns `NULL` if the argument is `NULL`.

An error results when `json_val` is not `NULL`, and is not—or cannot be successfully parsed as—a JSON document.

To illustrate this function's behavior when used with a `JSON` column as its argument, we create a table named `jtable` containing a `JSON` column `jcol`, insert a JSON value into the table, then obtain the storage space used by this column with `JSON_STORAGE_SIZE()`, as shown here:

```
mysql> CREATE TABLE jtable (jcol JSON);
Query OK, 0 rows affected (0.42 sec)

mysql> INSERT INTO jtable VALUES
-> ('{"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"}');
Query OK, 1 row affected (0.04 sec)

mysql> SELECT
->     jcol,
->     JSON_STORAGE_SIZE(jcol) AS Size,
->     JSON_STORAGE_FREE(jcol) AS Free
-> FROM jtable;
```

jcol	Size	Free
{"a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]"}	47	0

```
1 row in set (0.00 sec)
```

According to the output of `JSON_STORAGE_SIZE()`, the JSON document inserted into the column takes up 47 bytes. We also checked the amount of space freed by any previous partial updates of the column using `JSON_STORAGE_FREE()`; since no updates have yet been performed, this is 0, as expected.

Next we perform an `UPDATE` on the table that should result in a partial update of the document stored in `jcol`, and then test the result as shown here:

```
mysql> UPDATE jtable SET jcol =
->     JSON_SET(jcol, "$.b", "a");
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT
->     jcol,
->     JSON_STORAGE_SIZE(jcol) AS Size,
->     JSON_STORAGE_FREE(jcol) AS Free
-> FROM jtable;
```

jcol	Size	Free
{"a": 1000, "b": "a", "c": "[1, 3, 5, 7]"}	47	3

```
1 row in set (0.00 sec)
```

The value returned by `JSON_STORAGE_FREE()` in the previous query indicates that a partial update of the JSON document was performed, and that this freed 3 bytes of space used to store it. The result returned by `JSON_STORAGE_SIZE()` is unchanged by the partial update.

Partial updates are supported for updates using `JSON_SET()`, `JSON_REPLACE()`, or `JSON_REMOVE()`. The direct assignment of a value to a `JSON` column cannot be partially updated;

following such an update, `JSON_STORAGE_SIZE()` always shows the storage used for the newly-set value:

```
mysql> UPDATE jtable
mysql> SET jcol = '{"a": 4.55, "b": "wxyz", "c": "[true, false]"}';
Query OK, 1 row affected (0.04 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT
-> jcol,
-> JSON_STORAGE_SIZE(jcol) AS Size,
-> JSON_STORAGE_FREE(jcol) AS Free
-> FROM jtable;
```

jcol	Size	Free
{ "a": 4.55, "b": "wxyz", "c": "[true, false]" }	56	0

```
1 row in set (0.00 sec)
```

A JSON user variable cannot be partially updated. This means that this function always shows the space currently used to store a JSON document in a user variable:

```
mysql> SET @j = '[100, "sakila", [1, 3, 5], 425.05]';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
```

@j	Size
[100, "sakila", [1, 3, 5], 425.05]	45

```
1 row in set (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$[1]', "json");
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
```

@j	Size
[100, "json", [1, 3, 5], 425.05]	43

```
1 row in set (0.00 sec)

mysql> SET @j = JSON_SET(@j, '$[2][0]', JSON_ARRAY(10, 20, 30));
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @j, JSON_STORAGE_SIZE(@j) AS Size;
```

@j	Size
[100, "json", [[10, 20, 30], 3, 5], 425.05]	56

```
1 row in set (0.00 sec)
```

For a JSON literal, this function always returns the current storage space used:

```
mysql> SELECT
-> JSON_STORAGE_SIZE('[100, "sakila", [1, 3, 5], 425.05]') AS A,
-> JSON_STORAGE_SIZE('{ "a": 1000, "b": "a", "c": "[1, 3, 5, 7]" }') AS B,
-> JSON_STORAGE_SIZE('{ "a": 1000, "b": "wxyz", "c": "[1, 3, 5, 7]" }') AS C,
-> JSON_STORAGE_SIZE('[100, "json", [[10, 20, 30], 3, 5], 425.05]') AS D;
```

A	B	C	D
45	44	47	56

```
1 row in set (0.00 sec)
```

12.19 Functions Used with Global Transaction Identifiers (GTIDs)

The functions described in this section are used with GTID-based replication. It is important to keep in mind that all of these functions take string representations of GTID sets as arguments. As such, the GTID sets must always be quoted when used with them. See [GTID Sets](#) for more information.

The union of two GTID sets is simply their representations as strings, joined together with an interposed comma. In other words, you can define a very simple function for obtaining the union of two GTID sets, similar to that created here:

```
CREATE FUNCTION GTID_UNION(g1 TEXT, g2 TEXT)
  RETURNS TEXT DETERMINISTIC
  RETURN CONCAT(g1,',',g2);
```

For more information about GTIDs and how these GTID functions are used in practice, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

Table 12.24 GTID Functions

Name	Description
GTID_SUBSET()	Return true if all GTIDs in subset are also in set; otherwise false.
GTID_SUBTRACT()	Return all GTIDs in set that are not in subset.
WAIT_FOR_EXECUTED_GTID_SET()	Wait until the given GTIDs have executed on the replica.
WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS() (deprecated 8.0.18)	Use WAIT_FOR_EXECUTED_GTID_SET() .

- [GTID_SUBSET\(set1,set2\)](#)

Given two sets of global transaction identifiers *set1* and *set2*, returns true if all GTIDs in *set1* are also in *set2*. Returns false otherwise.

The GTID sets used with this function are represented as strings, as shown in the following examples:

```
mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:23-25',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 1
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57')\G
***** 1. row *****
GTID_SUBSET('3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57'): 0
1 row in set (0.00 sec)
```

- [GTID_SUBTRACT\(set1,set2\)](#)

Given two sets of global transaction identifiers *set1* and *set2*, returns only those GTIDs from *set1* that are not in *set2*.

All GTID sets used with this function are represented as strings and must be quoted, as shown in these examples:

```

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:21')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:21'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:22-57
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:20-25'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:26-57
1 row in set (0.00 sec)

mysql> SELECT GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
-> '3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24')\G
***** 1. row *****
GTID_SUBTRACT('3E11FA47-71CA-11E1-9E33-C80AA9429562:21-57',
'3E11FA47-71CA-11E1-9E33-C80AA9429562:23-24'): 3e11fa47-71ca-11e1-9e33-c80aa9429562:21-22:25-57
1 row in set (0.01 sec)

```

- `WAIT_FOR_EXECUTED_GTID_SET(gtid_set [, timeout])`

Wait until the server has applied all of the transactions whose global transaction identifiers are contained in *gtid_set*; that is, until the condition `GTID_SUBSET(gtid_subset, @@GLOBAL.gtid_executed)` holds. See [Section 17.1.3.1, “GTID Format and Storage”](#) for a definition of GTID sets.

If a timeout is specified, and *timeout* seconds elapse before all of the transactions in the GTID set have been applied, the function stops waiting. *timeout* is optional, and the default timeout is 0 seconds, in which case the function always waits until all of the transactions in the GTID set have been applied.

`WAIT_FOR_EXECUTED_GTID_SET()` monitors all the GTIDs that are applied on the server, including transactions that arrive from all replication channels and user clients. It does not take into account whether replication channels have been started or stopped.

For more information, see [Section 17.1.3, “Replication with Global Transaction Identifiers”](#).

GTID sets used with this function are represented as strings and so must be quoted as shown in the following example:

```

mysql> SELECT WAIT_FOR_EXECUTED_GTID_SET('3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5');
-> 0

```

For a syntax description for GTID sets, see [Section 17.1.3.1, “GTID Format and Storage”](#).

For `WAIT_FOR_EXECUTED_GTID_SET()`, the return value is the state of the query, where 0 represents success, and 1 represents timeout. Any other failures generate an error.

gtid_mode cannot be changed to OFF while any client is using this function to wait for GTIDs to be applied.

- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS(gtid_set [, timeout] [, channel])`

`WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()` is deprecated. Use `WAIT_FOR_EXECUTED_GTID_SET()` instead, which works regardless of the replication channel or user client through which the specified transactions arrive on the server.

12.20 Aggregate Functions

Aggregate functions operate on sets of values. They are often used with a `GROUP BY` clause to group values into subsets.

12.20.1 Aggregate Function Descriptions

This section describes aggregate functions that operate on sets of values. They are often used with a `GROUP BY` clause to group values into subsets.

Table 12.25 Aggregate Functions

Name	Description
<code>AVG()</code>	Return the average value of the argument
<code>BIT_AND()</code>	Return bitwise AND
<code>BIT_OR()</code>	Return bitwise OR
<code>BIT_XOR()</code>	Return bitwise XOR
<code>COUNT()</code>	Return a count of the number of rows returned
<code>COUNT(DISTINCT)</code>	Return the count of a number of different values
<code>GROUP_CONCAT()</code>	Return a concatenated string
<code>JSON_ARRAYAGG()</code>	Return result set as a single JSON array
<code>JSON_OBJECTAGG()</code>	Return result set as a single JSON object
<code>MAX()</code>	Return the maximum value
<code>MIN()</code>	Return the minimum value
<code>STD()</code>	Return the population standard deviation
<code>STDDEV()</code>	Return the population standard deviation
<code>STDDEV_POP()</code>	Return the population standard deviation
<code>STDDEV_SAMP()</code>	Return the sample standard deviation
<code>SUM()</code>	Return the sum
<code>VAR_POP()</code>	Return the population standard variance
<code>VAR_SAMP()</code>	Return the sample variance
<code>VARIANCE()</code>	Return the population standard variance

Unless otherwise stated, aggregate functions ignore `NULL` values.

If you use an aggregate function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows. For more information, see [Section 12.20.3, “MySQL Handling of GROUP BY”](#).

Most aggregate functions can be used as window functions. Those that can be used this way are signified in their syntax description by `[over_clause]`, representing an optional `OVER` clause. `over_clause` is described in [Section 12.21.2, “Window Function Concepts and Syntax”](#), which also includes other information about window function usage.

For numeric arguments, the variance and standard deviation functions return a `DOUBLE` value. The `SUM()` and `AVG()` functions return a `DECIMAL` value for exact-value arguments (integer or `DECIMAL`), and a `DOUBLE` value for approximate-value arguments (`FLOAT` or `DOUBLE`).

The `SUM()` and `AVG()` aggregate functions do not work with temporal values. (They convert the values to numbers, losing everything after the first nonnumeric character.) To work around this problem, convert to numeric units, perform the aggregate operation, and convert back to a temporal value. Examples:

```
SELECT SEC_TO_TIME(SUM(TIME_TO_SEC(time_col))) FROM tbl_name;
SELECT FROM_DAYS(SUM(TO_DAYS(date_col))) FROM tbl_name;
```

Functions such as `SUM()` or `AVG()` that expect a numeric argument cast the argument to a number if necessary. For `SET` or `ENUM` values, the cast operation causes the underlying numeric value to be used.

The `BIT_AND()`, `BIT_OR()`, and `BIT_XOR()` aggregate functions perform bit operations. Prior to MySQL 8.0, bit functions and operators required `BIGINT` (64-bit integer) arguments and returned `BIGINT` values, so they had a maximum range of 64 bits. Non-`BIGINT` arguments were converted to `BIGINT` prior to performing the operation and truncation could occur.

In MySQL 8.0, bit functions and operators permit binary string type arguments (`BINARY`, `VARBINARY`, and the `BLOB` types) and return a value of like type, which enables them to take arguments and produce return values larger than 64 bits. For discussion about argument evaluation and result types for bit operations, see the introductory discussion in [Section 12.13, “Bit Functions and Operators”](#).

- `AVG([DISTINCT] expr) [over_clause]`

Returns the average value of *expr*. The `DISTINCT` option can be used to return the average of the distinct values of *expr*.

If there are no matching rows, `AVG()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

```
mysql> SELECT student_name, AVG(test_score)
       FROM student
       GROUP BY student_name;
```

- `BIT_AND(expr) [over_clause]`

Returns the bitwise `AND` of all bits in *expr*.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_AND()` returns a neutral value (all bits set to 1) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in [Section 12.13, “Bit Functions and Operators”](#).

As of MySQL 8.0.12, this function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `BIT_OR(expr) [over_clause]`

Returns the bitwise `OR` of all bits in *expr*.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_OR()` returns a neutral value (all bits set to 0) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in [Section 12.13, “Bit Functions and Operators”](#).

As of MySQL 8.0.12, this function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `BIT_XOR(expr) [over_clause]`

Returns the bitwise `XOR` of all bits in `expr`.

The result type depends on whether the function argument values are evaluated as binary strings or numbers:

- Binary-string evaluation occurs when the argument values have a binary string type, and the argument is not a hexadecimal literal, bit literal, or `NULL` literal. Numeric evaluation occurs otherwise, with argument value conversion to unsigned 64-bit integers as necessary.
- Binary-string evaluation produces a binary string of the same length as the argument values. If argument values have unequal lengths, an `ER_INVALID_BITWISE_OPERANDS_SIZE` error occurs. If the argument size exceeds 511 bytes, an `ER_INVALID_BITWISE_AGGREGATE_OPERANDS_SIZE` error occurs. Numeric evaluation produces an unsigned 64-bit integer.

If there are no matching rows, `BIT_XOR()` returns a neutral value (all bits set to 0) having the same length as the argument values.

`NULL` values do not affect the result unless all values are `NULL`. In that case, the result is a neutral value having the same length as the argument values.

For more information discussion about argument evaluation and result types, see the introductory discussion in [Section 12.13, “Bit Functions and Operators”](#).

As of MySQL 8.0.12, this function executes as a window function if `over_clause` is present. `over_clause` is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `COUNT(expr) [over_clause]`

Returns a count of the number of non-`NULL` values of *expr* in the rows retrieved by a `SELECT` statement. The result is a `BIGINT` value.

If there are no matching rows, `COUNT()` returns 0.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

```
mysql> SELECT student.student_name,COUNT(*)
        FROM student,course
        WHERE student.student_id=course.student_id
        GROUP BY student_name;
```

`COUNT(*)` is somewhat different in that it returns a count of the number of rows retrieved, whether or not they contain `NULL` values.

For transactional storage engines such as `InnoDB`, storing an exact row count is problematic. Multiple transactions may be occurring at the same time, each of which may affect the count.

`InnoDB` does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

As of MySQL 8.0.13, `SELECT COUNT(*) FROM tbl_name` query performance for `InnoDB` tables is optimized for single-threaded workloads if there are no extra clauses such as `WHERE` or `GROUP BY`.

`InnoDB` processes `SELECT COUNT(*)` statements by traversing the smallest available secondary index unless an index or optimizer hint directs the optimizer to use a different index. If a secondary index is not present, `InnoDB` processes `SELECT COUNT(*)` statements by scanning the clustered index.

Processing `SELECT COUNT(*)` statements takes some time if index records are not entirely in the buffer pool. For a faster count, create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, use `SHOW TABLE STATUS`.

`InnoDB` handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

For `MyISAM` tables, `COUNT(*)` is optimized to return very quickly if the `SELECT` retrieves from one table, no other columns are retrieved, and there is no `WHERE` clause. For example:

```
mysql> SELECT COUNT(*) FROM student;
```

This optimization only applies to `MyISAM` tables, because an exact row count is stored for this storage engine and can be accessed very quickly. `COUNT(1)` is only subject to the same optimization if the first column is defined as `NOT NULL`.

- `COUNT(DISTINCT expr, [expr...])`

Returns a count of the number of rows with different non-`NULL` *expr* values.

If there are no matching rows, `COUNT(DISTINCT)` returns 0.

```
mysql> SELECT COUNT(DISTINCT results) FROM student;
```

In MySQL, you can obtain the number of distinct expression combinations that do not contain `NULL` by giving a list of expressions. In standard SQL, you would have to do a concatenation of all expressions inside `COUNT(DISTINCT ...)`.

- `GROUP_CONCAT(expr)`

This function returns a string result with the concatenated non-`NULL` values from a group. It returns `NULL` if there are no non-`NULL` values. The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
               [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val])
```

```
mysql> SELECT student_name,
           GROUP_CONCAT(test_score)
FROM student
GROUP BY student_name;
```

Or:

```
mysql> SELECT student_name,
           GROUP_CONCAT(DISTINCT test_score
                        ORDER BY test_score DESC SEPARATOR ' ')
FROM student
GROUP BY student_name;
```

In MySQL, you can get the concatenated values of expression combinations. To eliminate duplicate values, use the `DISTINCT` clause. To sort values in the result, use the `ORDER BY` clause. To sort in reverse order, add the `DESC` (descending) keyword to the name of the column you are sorting by in the `ORDER BY` clause. The default is ascending order; this may be specified explicitly using the `ASC` keyword. The default separator between values in a group is comma (,). To specify a separator explicitly, use `SEPARATOR` followed by the string literal value that should be inserted between group values. To eliminate the separator altogether, specify `SEPARATOR ''`.

The result is truncated to the maximum length that is given by the `group_concat_max_len` system variable, which has a default value of 1024. The value can be set higher, although the effective maximum length of the return value is constrained by the value of `max_allowed_packet`. The syntax to change the value of `group_concat_max_len` at runtime is as follows, where *val* is an unsigned integer:

```
SET [GLOBAL | SESSION] group_concat_max_len = val;
```

The return value is a nonbinary or binary string, depending on whether the arguments are nonbinary or binary strings. The result type is `TEXT` or `BLOB` unless `group_concat_max_len` is less than or equal to 512, in which case the result type is `VARCHAR` or `VARBINARY`.

See also `CONCAT()` and `CONCAT_WS()`: [Section 12.8, “String Functions and Operators”](#).

- `JSON_ARRAYAGG(col_or_expr) [over_clause]`

Aggregates a result set as a single `JSON` array whose elements consist of the rows. The order of elements in this array is undefined. The function acts on a column or an expression that evaluates to a single value. Returns `NULL` if the result contains no rows, or in the event of an error.

As of MySQL 8.0.14, this function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

```
mysql> SELECT o_id, attribute, value FROM t3;
+-----+-----+-----+
| o_id | attribute | value |
+-----+-----+-----+
|    2 | color    | red   |
|    2 | fabric   | silk  |
|    3 | color    | green |
|    3 | shape    | square|
+-----+-----+-----+
4 rows in set (0.00 sec)
```

```
mysql> SELECT o_id, JSON_ARRAYAGG(attribute) AS attributes
> FROM t3 GROUP BY o_id;
+-----+-----+
| o_id | attributes |
+-----+-----+
|    2 | ["color", "fabric"] |
|    3 | ["color", "shape"] |
+-----+-----+
2 rows in set (0.00 sec)
```

- `JSON_OBJECTAGG(key, value) [over_clause]`

Takes two column names or expressions as arguments, the first of these being used as a key and the second as a value, and returns a JSON object containing key-value pairs. Returns `NULL` if the result contains no rows, or in the event of an error. An error occurs if any key name is `NULL` or the number of arguments is not equal to 2.

As of MySQL 8.0.14, this function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

```
mysql> SELECT o_id, attribute, value FROM t3;
+-----+-----+-----+
| o_id | attribute | value |
+-----+-----+-----+
|    2 | color    | red   |
|    2 | fabric   | silk  |
|    3 | color    | green |
|    3 | shape    | square|
+-----+-----+-----+
4 rows in set (0.00 sec)
```

```
mysql> SELECT o_id, JSON_OBJECTAGG(attribute, value)
> FROM t3 GROUP BY o_id;
+-----+-----+
| o_id | JSON_OBJECTAGG(attribute, value) |
+-----+-----+
|    2 | {"color": "red", "fabric": "silk"} |
|    3 | {"color": "green", "shape": "square"} |
+-----+-----+
2 rows in set (0.00 sec)
```

Duplicate key handling. When the result of this function is normalized, values having duplicate keys are discarded. In keeping with the MySQL `JSON` data type specification that does not permit duplicate keys, only the last value encountered is used with that key in the returned object (“last

duplicate key wins"). This means that the result of using this function on columns from a `SELECT` can depend on the order in which the rows are returned, which is not guaranteed.

When used as a window function, if there are duplicate keys within a frame, only the last value for the key is present in the result. The value for the key from the last row in the frame is deterministic if the `ORDER BY` specification guarantees that the values have a specific order. If not, the resulting value of the key is nondeterministic.

Consider the following:

```
mysql> CREATE TABLE t(c VARCHAR(10), i INT);
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 4), ('key', 5);
Query OK, 3 rows affected (0.10 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c, i FROM t;
+-----+-----+
| c     | i     |
+-----+-----+
| key   | 3     |
| key   | 4     |
| key   | 5     |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+-----+
| JSON_OBJECTAGG(c, i) |
+-----+
| {"key": 5}           |
+-----+
1 row in set (0.00 sec)

mysql> DELETE FROM t;
Query OK, 3 rows affected (0.08 sec)

mysql> INSERT INTO t VALUES ('key', 3), ('key', 5), ('key', 4);
Query OK, 3 rows affected (0.06 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT c, i FROM t;
+-----+-----+
| c     | i     |
+-----+-----+
| key   | 3     |
| key   | 5     |
| key   | 4     |
+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT JSON_OBJECTAGG(c, i) FROM t;
+-----+
| JSON_OBJECTAGG(c, i) |
+-----+
| {"key": 4}           |
+-----+
1 row in set (0.00 sec)
```

The key chosen from the last query is nondeterministic. If you prefer a particular key ordering, you can invoke `JSON_OBJECTAGG()` as a window function by including an `OVER` clause with an `ORDER BY` specification to impose a particular order on frame rows. The following examples show what happens with and without `ORDER BY` for a few different frame specifications.

Without `ORDER BY`, the frame is the entire partition:

```
mysql> SELECT JSON_OBJECTAGG(c, i)
       OVER () AS json_object FROM t;
```

```
+-----+
| json_object |
+-----+
| {"key": 4} |
| {"key": 4} |
| {"key": 4} |
+-----+
```

With `ORDER BY`, where the frame is the default of `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW` (in both ascending and descending order):

```
mysql> SELECT JSON_OBJECTAGG(c, i)
        OVER (ORDER BY i) AS json_object FROM t;
+-----+
| json_object |
+-----+
| {"key": 3} |
| {"key": 4} |
| {"key": 5} |
+-----+

mysql> SELECT JSON_OBJECTAGG(c, i)
        OVER (ORDER BY i DESC) AS json_object FROM t;
+-----+
| json_object |
+-----+
| {"key": 5} |
| {"key": 4} |
| {"key": 3} |
+-----+
```

With `ORDER BY` and an explicit frame of the entire partition:

```
mysql> SELECT JSON_OBJECTAGG(c, i)
        OVER (ORDER BY i
              ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING)
        AS json_object
        FROM t;
+-----+
| json_object |
+-----+
| {"key": 5} |
| {"key": 5} |
| {"key": 5} |
+-----+
```

To return a particular key value (such as the smallest or largest), include a `LIMIT` clause in the appropriate query. For example:

```
mysql> SELECT JSON_OBJECTAGG(c, i)
        OVER (ORDER BY i) AS json_object FROM t LIMIT 1;
+-----+
| json_object |
+-----+
| {"key": 3} |
+-----+

mysql> SELECT JSON_OBJECTAGG(c, i)
        OVER (ORDER BY i DESC) AS json_object FROM t LIMIT 1;
+-----+
| json_object |
+-----+
| {"key": 5} |
+-----+
```

See [Normalization, Merging, and Autowrapping of JSON Values](#), for additional information and examples.

- `MAX([DISTINCT] expr) [over_clause]`

Returns the maximum value of *expr*. `MAX()` may take a string argument; in such cases, it returns the maximum string value. See [Section 8.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MAX()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
       FROM student
       GROUP BY student_name;
```

For `MAX()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- `MIN([DISTINCT] expr) [over_clause]`

Returns the minimum value of *expr*. `MIN()` may take a string argument; in such cases, it returns the minimum string value. See [Section 8.3.1, “How MySQL Uses Indexes”](#). The `DISTINCT` keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

If there are no matching rows, `MIN()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

```
mysql> SELECT student_name, MIN(test_score), MAX(test_score)
       FROM student
       GROUP BY student_name;
```

For `MIN()`, MySQL currently compares `ENUM` and `SET` columns by their string value rather than by the string's relative position in the set. This differs from how `ORDER BY` compares them.

- `STD(expr) [over_clause]`

Returns the population standard deviation of *expr*. `STD()` is a synonym for the standard SQL function `STDDEV_POP()`, provided as a MySQL extension.

If there are no matching rows, `STD()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `STDDEV(expr) [over_clause]`

Returns the population standard deviation of *expr*. `STDDEV()` is a synonym for the standard SQL function `STDDEV_POP()`, provided for compatibility with Oracle.

If there are no matching rows, `STDDEV()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `STDDEV_POP(expr) [over_clause]`

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

If there are no matching rows, `STDDEV_POP()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `STDDEV_SAMP(expr) [over_clause]`

Returns the sample standard deviation of *expr* (the square root of `VAR_SAMP()`).

If there are no matching rows, `STDDEV_SAMP()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `SUM([DISTINCT] expr) [over_clause]`

Returns the sum of *expr*. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of *expr*.

If there are no matching rows, `SUM()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#); it cannot be used with `DISTINCT`.

- `VAR_POP(expr) [over_clause]`

Returns the population standard variance of *expr*. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use `VARIANCE()`, which is equivalent but is not standard SQL.

If there are no matching rows, `VAR_POP()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `VAR_SAMP(expr) [over_clause]`

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one.

If there are no matching rows, `VAR_SAMP()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `VARIANCE(expr) [over_clause]`

Returns the population standard variance of *expr*. `VARIANCE()` is a synonym for the standard SQL function `VAR_POP()`, provided as a MySQL extension.

If there are no matching rows, `VARIANCE()` returns `NULL`.

This function executes as a window function if *over_clause* is present. *over_clause* is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

The `GROUP BY` clause permits a `WITH ROLLUP` modifier that causes summary output to include extra rows that represent higher-level (that is, super-aggregate) summary operations. `ROLLUP` thus enables you to answer questions at multiple levels of analysis with a single query. For example, `ROLLUP` can be used to provide support for OLAP (Online Analytical Processing) operations.

Suppose that a `sales` table has `year`, `country`, `product`, and `profit` columns for recording sales profitability:

```
CREATE TABLE sales
(
    year      INT,
    country   VARCHAR(20),
    product   VARCHAR(32),
    profit    INT
);
```

To summarize table contents per year, use a simple `GROUP BY` like this:

```
mysql> SELECT year, SUM(profit) AS profit
        FROM sales
        GROUP BY year;
+-----+-----+
| year | profit |
+-----+-----+
| 2000 | 4525   |
| 2001 | 3010   |
+-----+-----+
```

The output shows the total (aggregate) profit for each year. To also determine the total profit summed over all years, you must add up the individual values yourself or run an additional query. Or you can use `ROLLUP`, which provides both levels of analysis with a single query. Adding a `WITH ROLLUP` modifier to the `GROUP BY` clause causes the query to produce another (super-aggregate) row that shows the grand total over all year values:

```
mysql> SELECT year, SUM(profit) AS profit
        FROM sales
        GROUP BY year WITH ROLLUP;
+-----+-----+
| year | profit |
+-----+-----+
| 2000 | 4525   |
| 2001 | 3010   |
| NULL | 7535   |
+-----+-----+
```

The `NULL` value in the `year` column identifies the grand total super-aggregate line.

`ROLLUP` has a more complex effect when there are multiple `GROUP BY` columns. In this case, each time there is a change in value in any but the last grouping column, the query produces an extra super-aggregate summary row.

For example, without `ROLLUP`, a summary of the `sales` table based on `year`, `country`, and `product` might look like this, where the output indicates summary values only at the year/country/product level of analysis:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
        FROM sales
        GROUP BY year, country, product;
+-----+-----+-----+-----+
| year | country | product | profit |
+-----+-----+-----+-----+
| 2000 | Finland | Computer | 1500   |
| 2000 | Finland | Phone   | 100    |
| 2000 | India   | Calculator | 150    |
| 2000 | India   | Computer | 1200   |
| 2000 | USA     | Calculator | 75     |
| 2000 | USA     | Computer | 1500   |
| 2001 | Finland | Phone   | 10     |
```

2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250

With `ROLLUP` added, the query produces several extra rows:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP;
```

year	country	product	profit
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200
2000	India	NULL	1350
2000	USA	Calculator	75
2000	USA	Computer	1500
2000	USA	NULL	1575
2000	NULL	NULL	4525
2001	Finland	Phone	10
2001	Finland	NULL	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250
2001	USA	NULL	3000
2001	NULL	NULL	3010
NULL	NULL	NULL	7535

Now the output includes summary information at four levels of analysis, not just one:

- Following each set of product rows for a given year and country, an extra super-aggregate summary row appears showing the total for all products. These rows have the `product` column set to `NULL`.
- Following each set of rows for a given year, an extra super-aggregate summary row appears showing the total for all countries and products. These rows have the `country` and `products` columns set to `NULL`.
- Finally, following all other rows, an extra super-aggregate summary row appears showing the grand total for all years, countries, and products. This row has the `year`, `country`, and `products` columns set to `NULL`.

The `NULL` indicators in each super-aggregate row are produced when the row is sent to the client. The server looks at the columns named in the `GROUP BY` clause following the leftmost one that has changed value. For any column in the result set with a name that matches any of those names, its value is set to `NULL`. (If you specify grouping columns by column position, the server identifies which columns to set to `NULL` by position.)

Because the `NULL` values in the super-aggregate rows are placed into the result set at such a late stage in query processing, you can test them as `NULL` values only in the select list or `HAVING` clause. You cannot test them as `NULL` values in join conditions or the `WHERE` clause to determine which rows to select. For example, you cannot add `WHERE product IS NULL` to the query to eliminate from the output all but the super-aggregate rows.

The `NULL` values do appear as `NULL` on the client side and can be tested as such using any MySQL client programming interface. However, at this point, you cannot distinguish whether a `NULL` represents a regular grouped value or a super-aggregate value. To test the distinction, use the `GROUPING()` function, described later.

Previously, MySQL did not allow the use of `DISTINCT` or `ORDER BY` in a query having a `WITH ROLLUP` option. This restriction is lifted in MySQL 8.0.12 and later. (Bug #87450, Bug #86311, Bug #26640100, Bug #26073513)

For `GROUP BY ... WITH ROLLUP` queries, to test whether `NULL` values in the result represent super-aggregate values, the `GROUPING()` function is available for use in the select list, `HAVING` clause, and (as of MySQL 8.0.12) `ORDER BY` clause. For example, `GROUPING(year)` returns 1 when `NULL` in the `year` column occurs in a super-aggregate row, and 0 otherwise. Similarly, `GROUPING(country)` and `GROUPING(product)` return 1 for super-aggregate `NULL` values in the `country` and `product` columns, respectively:

```
mysql> SELECT
    year, country, product, SUM(profit) AS profit,
    GROUPING(year) AS grp_year,
    GROUPING(country) AS grp_country,
    GROUPING(product) AS grp_product
FROM sales
GROUP BY year, country, product WITH ROLLUP;
```

year	country	product	profit	grp_year	grp_country	grp_product
2000	Finland	Computer	1500	0	0	0
2000	Finland	Phone	100	0	0	0
2000	Finland	NULL	1600	0	0	1
2000	India	Calculator	150	0	0	0
2000	India	Computer	1200	0	0	0
2000	India	NULL	1350	0	0	1
2000	USA	Calculator	75	0	0	0
2000	USA	Computer	1500	0	0	0
2000	USA	NULL	1575	0	0	1
2000	NULL	NULL	4525	0	1	1
2001	Finland	Phone	10	0	0	0
2001	Finland	NULL	10	0	0	1
2001	USA	Calculator	50	0	0	0
2001	USA	Computer	2700	0	0	0
2001	USA	TV	250	0	0	0
2001	USA	NULL	3000	0	0	1
2001	NULL	NULL	3010	0	1	1
NULL	NULL	NULL	7535	1	1	1

Instead of displaying the `GROUPING()` results directly, you can use `GROUPING()` to substitute labels for super-aggregate `NULL` values:

```
mysql> SELECT
    IF(GROUPING(year), 'All years', year) AS year,
    IF(GROUPING(country), 'All countries', country) AS country,
    IF(GROUPING(product), 'All products', product) AS product,
    SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP;
```

year	country	product	profit
2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	All products	1600
2000	India	Calculator	150
2000	India	Computer	1200
2000	India	All products	1350
2000	USA	Calculator	75
2000	USA	Computer	1500
2000	USA	All products	1575
2000	All countries	All products	4525
2001	Finland	Phone	10
2001	Finland	All products	10
2001	USA	Calculator	50
2001	USA	Computer	2700
2001	USA	TV	250
2001	USA	All products	3000
2001	All countries	All products	3010
All years	All countries	All products	7535

With multiple expression arguments, `GROUPING()` returns a result representing a bitmask the combines the results for each expression, with the lowest-order bit corresponding to the result for the rightmost expression. For example, `GROUPING(year, country, product)` is evaluated like this:

```
result for GROUPING(product)
+ result for GROUPING(country) << 1
+ result for GROUPING(year) << 2
```

The result of such a `GROUPING()` is nonzero if any of the expressions represents a super-aggregate `NULL`, so you can return only the super-aggregate rows and filter out the regular grouped rows like this:

```
mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP
HAVING GROUPING(year, country, product) <> 0;
```

year	country	product	profit
2000	Finland	NULL	1600
2000	India	NULL	1350
2000	USA	NULL	1575
2000	NULL	NULL	4525
2001	Finland	NULL	10
2001	USA	NULL	3000
2001	NULL	NULL	3010
NULL	NULL	NULL	7535

The `sales` table contains no `NULL` values, so all `NULL` values in a `ROLLUP` result represent super-aggregate values. When the data set contains `NULL` values, `ROLLUP` summaries may contain `NULL` values not only in super-aggregate rows, but also in regular grouped rows. `GROUPING()` enables these to be distinguished. Suppose that table `t1` contains a simple data set with two grouping factors for a set of quantity values, where `NULL` indicates something like “other” or “unknown”:

```
mysql> SELECT * FROM t1;
```

name	size	quantity
ball	small	10
ball	large	20
ball	NULL	5
hoop	small	15
hoop	large	5
hoop	NULL	3

A simple `ROLLUP` operation produces these results, in which it is not so easy to distinguish `NULL` values in super-aggregate rows from `NULL` values in regular grouped rows:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

name	size	quantity
ball	NULL	5
ball	large	20
ball	small	10
ball	NULL	35
hoop	NULL	3
hoop	large	5
hoop	small	15
hoop	NULL	23
NULL	NULL	58

Using `GROUPING()` to substitute labels for the super-aggregate `NULL` values makes the result easier to interpret:

```
mysql> SELECT
```

```

        IF(GROUPING(name) = 1, 'All items', name) AS name,
        IF(GROUPING(size) = 1, 'All sizes', size) AS size,
        SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;

```

name	size	quantity
ball	NULL	5
ball	large	20
ball	small	10
ball	All sizes	35
hoop	NULL	3
hoop	large	5
hoop	small	15
hoop	All sizes	23
All items	All sizes	58

Other Considerations When using ROLLUP

The following discussion lists some behaviors specific to the MySQL implementation of `ROLLUP`.

Prior to MySQL 8.0.12, when you use `ROLLUP`, you cannot also use an `ORDER BY` clause to sort the results. In other words, `ROLLUP` and `ORDER BY` were mutually exclusive in MySQL. However, you still have some control over sort order. To work around the restriction that prevents using `ROLLUP` with `ORDER BY` and achieve a specific sort order of grouped results, generate the grouped result set as a derived table and apply `ORDER BY` to it. For example:

```

mysql> SELECT * FROM
        (SELECT year, SUM(profit) AS profit
         FROM sales GROUP BY year WITH ROLLUP) AS dt
        ORDER BY year DESC;

```

year	profit
2001	3010
2000	4525
NULL	7535

As of MySQL 8.0.12, `ORDER BY` and `ROLLUP` can be used together, which enables the use of `ORDER BY` and `GROUPING()` to achieve a specific sort order of grouped results. For example:

```

mysql> SELECT year, SUM(profit) AS profit
FROM sales
GROUP BY year WITH ROLLUP
ORDER BY GROUPING(year) DESC;

```

year	profit
NULL	7535
2000	4525
2001	3010

In both cases, the super-aggregate summary rows sort with the rows from which they are calculated, and their placement depends on sort order (at the end for ascending sort, at the beginning for descending sort).

`LIMIT` can be used to restrict the number of rows returned to the client. `LIMIT` is applied after `ROLLUP`, so the limit applies against the extra rows added by `ROLLUP`. For example:

```

mysql> SELECT year, country, product, SUM(profit) AS profit
FROM sales
GROUP BY year, country, product WITH ROLLUP
LIMIT 5;

```

year	country	product	profit
------	---------	---------	--------

2000	Finland	Computer	1500
2000	Finland	Phone	100
2000	Finland	NULL	1600
2000	India	Calculator	150
2000	India	Computer	1200

Using `LIMIT` with `ROLLUP` may produce results that are more difficult to interpret, because there is less context for understanding the super-aggregate rows.

A MySQL extension permits a column that does not appear in the `GROUP BY` list to be named in the select list. (For information about nonaggregated columns and `GROUP BY`, see [Section 12.20.3, “MySQL Handling of GROUP BY”](#).) In this case, the server is free to choose any value from this nonaggregated column in summary rows, and this includes the extra rows added by `WITH ROLLUP`. For example, in the following query, `country` is a nonaggregated column that does not appear in the `GROUP BY` list and values chosen for this column are nondeterministic:

```
mysql> SELECT year, country, SUM(profit) AS profit
FROM sales
GROUP BY year WITH ROLLUP;
```

year	country	profit
2000	India	4525
2001	USA	3010
NULL	USA	7535

This behavior is permitted when the `ONLY_FULL_GROUP_BY` SQL mode is not enabled. If that mode is enabled, the server rejects the query as illegal because `country` is not listed in the `GROUP BY` clause. With `ONLY_FULL_GROUP_BY` enabled, you can still execute the query by using the `ANY_VALUE()` function for nondeterministic-value columns:

```
mysql> SELECT year, ANY_VALUE(country) AS country, SUM(profit) AS profit
FROM sales
GROUP BY year WITH ROLLUP;
```

year	country	profit
2000	India	4525
2001	USA	3010
NULL	USA	7535

12.20.3 MySQL Handling of GROUP BY

SQL-92 and earlier does not permit queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are not named in the `GROUP BY` clause. For example, this query is illegal in standard SQL-92 because the nonaggregated `name` column in the select list does not appear in the `GROUP BY`:

```
SELECT o.custid, c.name, MAX(o.payment)
FROM orders AS o, customers AS c
WHERE o.custid = c.custid
GROUP BY o.custid;
```

For the query to be legal in SQL-92, the `name` column must be omitted from the select list or named in the `GROUP BY` clause.

SQL:1999 and later permits such nonaggregates per optional feature T301 if they are functionally dependent on `GROUP BY` columns: If such a relationship exists between `name` and `custid`, the query is legal. This would be the case, for example, were `custid` a primary key of `customers`.

MySQL implements detection of functional dependence. If the `ONLY_FULL_GROUP_BY` SQL mode is enabled (which it is by default), MySQL rejects queries for which the select list, `HAVING` condition, or

`ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on them.

MySQL also permits a nonaggregate column not named in a `GROUP BY` clause when SQL `ONLY_FULL_GROUP_BY` mode is enabled, provided that this column is limited to a single value, as shown in the following example:

```
mysql> CREATE TABLE mytable (
->   id INT UNSIGNED NOT NULL PRIMARY KEY,
->   a VARCHAR(10),
->   b INT
-> );

mysql> INSERT INTO mytable
-> VALUES (1, 'abc', 1000),
->         (2, 'abc', 2000),
->         (3, 'def', 4000);

mysql> SET SESSION sql_mode = sys.list_add(@@session.sql_mode, 'ONLY_FULL_GROUP_BY');

mysql> SELECT a, SUM(b) FROM mytable WHERE a = 'abc';
+-----+-----+
| a    | SUM(b) |
+-----+-----+
| abc  | 3000   |
+-----+-----+
```

It is also possible to have more than one nonaggregate column in the `SELECT` list when employing `ONLY_FULL_GROUP_BY`. In this case, every such column must be limited to a single value in the `WHERE` clause, and all such limiting conditions must be joined by logical `AND`, as shown here:

```
mysql> DROP TABLE IF EXISTS mytable;

mysql> CREATE TABLE mytable (
->   id INT UNSIGNED NOT NULL PRIMARY KEY,
->   a VARCHAR(10),
->   b VARCHAR(10),
->   c INT
-> );

mysql> INSERT INTO mytable
-> VALUES (1, 'abc', 'qrs', 1000),
->         (2, 'abc', 'tuv', 2000),
->         (3, 'def', 'qrs', 4000),
->         (4, 'def', 'tuv', 8000),
->         (5, 'abc', 'qrs', 16000),
->         (6, 'def', 'tuv', 32000);

mysql> SELECT @@session.sql_mode;
+-----+-----+
| @@session.sql_mode |
+-----+-----+
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION |
+-----+-----+

mysql> SELECT a, b, SUM(c) FROM mytable
->       WHERE a = 'abc' AND b = 'qrs';
+-----+-----+-----+
| a    | b    | SUM(c) |
+-----+-----+-----+
| abc  | qrs  | 17000  |
+-----+-----+-----+
```

If `ONLY_FULL_GROUP_BY` is disabled, a MySQL extension to the standard SQL use of `GROUP BY` permits the select list, `HAVING` condition, or `ORDER BY` list to refer to nonaggregated columns even if the columns are not functionally dependent on `GROUP BY` columns. This causes MySQL to accept the preceding query. In this case, the server is free to choose any value from each group, so unless they are the same, the values chosen are nondeterministic, which is probably not what you want. Furthermore, the selection of values from each group cannot be influenced by adding an `ORDER BY`

clause. Result set sorting occurs after values have been chosen, and `ORDER BY` does not affect which value within each group the server chooses. Disabling `ONLY_FULL_GROUP_BY` is useful primarily when you know that, due to some property of the data, all values in each nonaggregated column not named in the `GROUP BY` are the same for each group.

You can achieve the same effect without disabling `ONLY_FULL_GROUP_BY` by using `ANY_VALUE()` to refer to the nonaggregated column.

The following discussion demonstrates functional dependence, the error message MySQL produces when functional dependence is absent, and ways of causing MySQL to accept a query in the absence of functional dependence.

This query might be invalid with `ONLY_FULL_GROUP_BY` enabled because the nonaggregated `address` column in the select list is not named in the `GROUP BY` clause:

```
SELECT name, address, MAX(age) FROM t GROUP BY name;
```

The query is valid if `name` is a primary key of `t` or is a unique `NOT NULL` column. In such cases, MySQL recognizes that the selected column is functionally dependent on a grouping column. For example, if `name` is a primary key, its value determines the value of `address` because each group has only one value of the primary key and thus only one row. As a result, there is no randomness in the choice of `address` value in a group and no need to reject the query.

The query is invalid if `name` is not a primary key of `t` or a unique `NOT NULL` column. In this case, no functional dependency can be inferred and an error occurs:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

If you know that, *for a given data set*, each `name` value in fact uniquely determines the `address` value, `address` is effectively functionally dependent on `name`. To tell MySQL to accept the query, you can use the `ANY_VALUE()` function:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

Alternatively, disable `ONLY_FULL_GROUP_BY`.

The preceding example is quite simple, however. In particular, it is unlikely you would group on a single primary key column because every group would contain only one row. For additional examples demonstrating functional dependence in more complex queries, see [Section 12.20.4, “Detection of Functional Dependence”](#).

If a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list, `HAVING` condition, or `ORDER BY` list with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'mydb.t.name'; this
is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. Here, too, `ANY_VALUE()` can be used, if it is immaterial which `name` value MySQL chooses:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

`ONLY_FULL_GROUP_BY` also affects handling of queries that use `DISTINCT` and `ORDER BY`. Consider the case of a table `t` with three columns `c1`, `c2`, and `c3` that contains these rows:

```
c1 c2 c3
1  2  A
3  4  B
1  2  C
```

Suppose that we execute the following query, expecting the results to be ordered by `c3`:

```
SELECT DISTINCT c1, c2 FROM t ORDER BY c3;
```

To order the result, duplicates must be eliminated first. But to do so, should we keep the first row or the third? This arbitrary choice influences the retained value of `c3`, which in turn influences ordering and makes it arbitrary as well. To prevent this problem, a query that has `DISTINCT` and `ORDER BY` is rejected as invalid if any `ORDER BY` expression does not satisfy at least one of these conditions:

- The expression is equal to one in the select list
- All columns referenced by the expression and belonging to the query's selected tables are elements of the select list

Another MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. For example, the following query returns `name` values that occur only once in table `orders`:

```
SELECT name, COUNT(name) FROM orders
GROUP BY name
HAVING COUNT(name) = 1;
```

The MySQL extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```
SELECT name, COUNT(name) AS c FROM orders
GROUP BY name
HAVING c = 1;
```

Standard SQL permits only column expressions in `GROUP BY` clauses, so a statement such as this is invalid because `FLOOR(value/100)` is a noncolumn expression:

```
SELECT id, FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

MySQL extends standard SQL to permit noncolumn expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. MySQL extends standard SQL to permit aliases, so another way to write the query is as follows:

```
SELECT id, FLOOR(value/100) AS val
FROM tbl_name
GROUP BY id, val;
```

The alias `val` is considered a column expression in the `GROUP BY` clause.

In the presence of a noncolumn expression in the `GROUP BY` clause, MySQL recognizes equality between that expression and expressions in the select list. This means that with `ONLY_FULL_GROUP_BY` SQL mode enabled, the query containing `GROUP BY id, FLOOR(value/100)` is valid because that same `FLOOR()` expression occurs in the select list. However, MySQL does not try to recognize functional dependence on `GROUP BY` noncolumn expressions, so the following query is invalid with `ONLY_FULL_GROUP_BY` enabled, even though the third selected expression is a simple formula of the `id` column and the `FLOOR()` expression in the `GROUP BY` clause:

```
SELECT id, FLOOR(value/100), id+FLOOR(value/100)
FROM tbl_name
GROUP BY id, FLOOR(value/100);
```

A workaround is to use a derived table:

```
SELECT id, F, id+F
FROM
  (SELECT id, FLOOR(value/100) AS F
   FROM tbl_name
   GROUP BY id, FLOOR(value/100)) AS dt;
```

12.20.4 Detection of Functional Dependence

The following discussion provides several examples of the ways in which MySQL detects functional dependencies. The examples use this notation:

```
{X} -> {Y}
```

Understand this as “*X* uniquely determines *Y*,” which also means that *Y* is functionally dependent on *X*.

The examples use the `world` database, which can be downloaded from <https://dev.mysql.com/doc/index-other.html>. You can find details on how to install the database on the same page.

- [Functional Dependencies Derived from Keys](#)
- [Functional Dependencies Derived from Multiple-Column Keys and from Equalities](#)
- [Functional Dependency Special Cases](#)
- [Functional Dependencies and Views](#)
- [Combinations of Functional Dependencies](#)

Functional Dependencies Derived from Keys

The following query selects, for each country, a count of spoken languages:

```
SELECT co.Name, COUNT(*)
FROM countrylanguage cl, country co
WHERE cl.CountryCode = co.Code
GROUP BY co.Code;
```

`co.Code` is a primary key of `co`, so all columns of `co` are functionally dependent on it, as expressed using this notation:

```
{co.Code} -> {co.*}
```

Thus, `co.name` is functionally dependent on `GROUP BY` columns and the query is valid.

A `UNIQUE` index over a `NOT NULL` column could be used instead of a primary key and the same functional dependence would apply. (This is not true for a `UNIQUE` index that permits `NULL` values because it permits multiple `NULL` values and in that case uniqueness is lost.)

Functional Dependencies Derived from Multiple-Column Keys and from Equalities

This query selects, for each country, a list of all spoken languages and how many people speak them:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population / 100.0 AS SpokenBy
FROM countrylanguage cl, country co
WHERE cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

The pair (`cl.CountryCode`, `cl.Language`) is a two-column composite primary key of `cl`, so that column pair uniquely determines all columns of `cl`:

```
{cl.CountryCode, cl.Language} -> {cl.*}
```

Moreover, because of the equality in the `WHERE` clause:

```
{cl.CountryCode} -> {co.Code}
```

And, because `co.Code` is primary key of `co`:

```
{co.Code} -> {co.*}
```

“Uniquely determines” relationships are transitive, therefore:

```
{cl.CountryCode, cl.Language} -> {cl.*, co.*}
```

As a result, the query is valid.

As with the previous example, a **UNIQUE** key over **NOT NULL** columns could be used instead of a primary key.

An **INNER JOIN** condition can be used instead of **WHERE**. The same functional dependencies apply:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl INNER JOIN country co
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

Functional Dependency Special Cases

Whereas an equality test in a **WHERE** condition or **INNER JOIN** condition is symmetric, an equality test in an outer join condition is not, because tables play different roles.

Assume that referential integrity has been accidentally broken and there exists a row of **countrylanguage** without a corresponding row in **country**. Consider the same query as in the previous example, but with a **LEFT JOIN**:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population/100.0 AS SpokenBy
FROM countrylanguage cl LEFT JOIN country co
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

For a given value of **cl.CountryCode**, the value of **co.Code** in the join result is either found in a matching row (determined by **cl.CountryCode**) or is **NULL**-complemented if there is no match (also determined by **cl.CountryCode**). In each case, this relationship applies:

```
{cl.CountryCode} -> {co.Code}
```

cl.CountryCode is itself functionally dependent on {**cl.CountryCode**, **cl.Language**} which is a primary key.

If in the join result **co.Code** is **NULL**-complemented, **co.Name** is as well. If **co.Code** is not **NULL**-complemented, then because **co.Code** is a primary key, it determines **co.Name**. Therefore, in all cases:

```
{co.Code} -> {co.Name}
```

Which yields:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

As a result, the query is valid.

However, suppose that the tables are swapped, as in this query:

```
SELECT co.Name, cl.Language,
cl.Percentage * co.Population/100.0 AS SpokenBy
FROM country co LEFT JOIN countrylanguage cl
ON cl.CountryCode = co.Code
GROUP BY cl.CountryCode, cl.Language;
```

Now this relationship does *not* apply:

```
{cl.CountryCode, cl.Language} -> {cl.*,co.*}
```

Indeed, all **NULL**-complemented rows made for **cl** will be put into a single group (they have both **GROUP BY** columns equal to **NULL**), and inside this group the value of **co.Name** can vary. The query is invalid and MySQL rejects it.

Functional dependence in outer joins is thus linked to whether determinant columns belong to the left or right side of the **LEFT JOIN**. Determination of functional dependence becomes more complex if there are nested outer joins or the join condition does not consist entirely of equality comparisons.

Functional Dependencies and Views

Suppose that a view on countries produces their code, their name in uppercase, and how many different official languages they have:

```
CREATE VIEW country2 AS
SELECT co.Code, UPPER(co.Name) AS UpperName,
COUNT(cl.Language) AS OfficialLanguages
FROM country AS co JOIN countrylanguage AS cl
ON cl.CountryCode = co.Code
WHERE cl.isOfficial = 'T'
GROUP BY co.Code;
```

This definition is valid because:

```
{co.Code} -> {co.*}
```

In the view result, the first selected column is `co.Code`, which is also the group column and thus determines all other selected expressions:

```
{country2.Code} -> {country2.*}
```

MySQL understands this and uses this information, as described following.

This query displays countries, how many different official languages they have, and how many cities they have, by joining the view with the `city` table:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM country2 AS co2 JOIN city ci
ON ci.CountryCode = co2.Code
GROUP BY co2.Code;
```

This query is valid because, as seen previously:

```
{co2.Code} -> {co2.*}
```

MySQL is able to discover a functional dependency in the result of a view and use that to validate a query which uses the view. The same would be true if `country2` were a derived table (or common table expression), as in:

```
SELECT co2.Code, co2.UpperName, co2.OfficialLanguages,
COUNT(*) AS Cities
FROM
(
  SELECT co.Code, UPPER(co.Name) AS UpperName,
  COUNT(cl.Language) AS OfficialLanguages
  FROM country AS co JOIN countrylanguage AS cl
  ON cl.CountryCode=co.Code
  WHERE cl.isOfficial='T'
  GROUP BY co.Code
) AS co2
JOIN city ci ON ci.CountryCode = co2.Code
GROUP BY co2.Code;
```

Combinations of Functional Dependencies

MySQL is able to combine all of the preceding types of functional dependencies (key based, equality based, view based) to validate more complex queries.

12.21 Window Functions

MySQL supports window functions that, for each row from a query, perform a calculation using rows related to that row. The following sections discuss how to use window functions, including descriptions of the `OVER` and `WINDOW` clauses. The first section provides descriptions of the nonaggregate window functions. For descriptions of the aggregate window functions, see [Section 12.20.1, “Aggregate Function Descriptions”](#).

For information about optimization and window functions, see [Section 8.2.1.21, “Window Function Optimization”](#).

12.21.1 Window Function Descriptions

This section describes nonaggregate window functions that, for each row from a query, perform a calculation using rows related to that row. Most aggregate functions also can be used as window functions; see [Section 12.20.1, “Aggregate Function Descriptions”](#).

For window function usage information and examples, and definitions of terms such as the [OVER](#) clause, window, partition, frame, and peer, see [Section 12.21.2, “Window Function Concepts and Syntax”](#).

Table 12.26 Window Functions

Name	Description
CUME_DIST()	Cumulative distribution value
DENSE_RANK()	Rank of current row within its partition, without gaps
FIRST_VALUE()	Value of argument from first row of window frame
LAG()	Value of argument from row lagging current row within partition
LAST_VALUE()	Value of argument from last row of window frame
LEAD()	Value of argument from row leading current row within partition
NTH_VALUE()	Value of argument from N-th row of window frame
NTILE()	Bucket number of current row within its partition.
PERCENT_RANK()	Percentage rank value
RANK()	Rank of current row within its partition, with gaps
ROW_NUMBER()	Number of current row within its partition

In the following function descriptions, *over_clause* represents the [OVER](#) clause, described in [Section 12.21.2, “Window Function Concepts and Syntax”](#). Some window functions permit a *null_treatment* clause that specifies how to handle [NULL](#) values when calculating results. This clause is optional. It is part of the SQL standard, but the MySQL implementation permits only [RESPECT NULLS](#) (which is also the default). This means that [NULL](#) values are considered when calculating results. [IGNORE NULLS](#) is parsed, but produces an error.

- [CUME_DIST\(\)](#) *over_clause*

Returns the cumulative distribution of a value within a group of values; that is, the percentage of partition values less than or equal to the value in the current row. This represents the number of rows preceding or peer with the current row in the window ordering of the window partition divided by the total number of rows in the window partition. Return values range from 0 to 1.

This function should be used with [ORDER BY](#) to sort partition rows into the desired order. Without [ORDER BY](#), all rows are peers and have value $N/N = 1$, where *N* is the partition size.

over_clause is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

The following query shows, for the set of values in the `val` column, the [CUME_DIST\(\)](#) value for each row, as well as the percentage rank value returned by the similar [PERCENT_RANK\(\)](#) function. For reference, the query also displays row numbers using [ROW_NUMBER\(\)](#):

```
mysql> SELECT
    val,
    ROW_NUMBER() OVER w AS 'row_number',
```

```

CUME_DIST() OVER w AS 'cume_dist',
PERCENT_RANK() OVER w AS 'percent_rank'
FROM numbers
WINDOW w AS (ORDER BY val);

```

val	row_number	cume_dist	percent_rank
1	1	0.2222222222222222	0
1	2	0.2222222222222222	0
2	3	0.3333333333333333	0.25
3	4	0.6666666666666666	0.375
3	5	0.6666666666666666	0.375
3	6	0.6666666666666666	0.375
4	7	0.8888888888888888	0.75
4	8	0.8888888888888888	0.75
5	9	1	1

- `DENSE_RANK()` *over_clause*

Returns the rank of the current row within its partition, without gaps. Peers are considered ties and receive the same rank. This function assigns consecutive ranks to peer groups; the result is that groups of size greater than one do not produce noncontiguous rank numbers. For an example, see the `RANK()` function description.

This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

over_clause is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

- `FIRST_VALUE(expr)` [*null_treatment*] *over_clause*

Returns the value of *expr* from the first row of the window frame.

over_clause is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

null_treatment is as described in the section introduction.

The following query demonstrates `FIRST_VALUE()`, `LAST_VALUE()`, and two instances of `NTH_VALUE()`:

```

mysql> SELECT
    time, subject, val,
    FIRST_VALUE(val) OVER w AS 'first',
    LAST_VALUE(val) OVER w AS 'last',
    NTH_VALUE(val, 2) OVER w AS 'second',
    NTH_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time
              ROWS UNBOUNDED PRECEDING);

```

time	subject	val	first	last	second	fourth
07:00:00	st113	10	10	10	NULL	NULL
07:15:00	st113	9	10	9	9	NULL
07:30:00	st113	25	10	25	9	NULL
07:45:00	st113	20	10	20	9	20
07:00:00	xh458	0	0	0	NULL	NULL
07:15:00	xh458	10	0	10	10	NULL
07:30:00	xh458	5	0	5	10	NULL
07:45:00	xh458	30	0	30	10	30
08:00:00	xh458	25	0	25	10	30

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the `NTH_VALUE()` calls, the current frame does not always include the requested row; in such cases, the return value is `NULL`.

- `LAG(expr [, N[, default]])` [*null_treatment*] *over_clause*

Returns the value of *expr* from the row that lags (precedes) the current row by *N* rows within its partition. If there is no such row, the return value is *default*. For example, if *N* is 3, the return value is *default* for the first two rows. If *N* or *default* are missing, the defaults are 1 and `NULL`, respectively.

N must be a literal nonnegative integer. If *N* is 0, *expr* is evaluated for the current row.

Beginning with MySQL 8.0.22, *N* cannot be `NULL`. In addition, it must now be an integer in the range 1 to 2^{63} , inclusive, in any of the following forms:

- an unsigned integer constant literal
- a positional parameter marker (?)
- a user-defined variable
- a local variable in a stored routine

over_clause is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

null_treatment is as described in the section introduction.

`LAG()` (and the similar `LEAD()` function) are often used to compute differences between rows. The following query shows a set of time-ordered observations and, for each one, the `LAG()` and `LEAD()` values from the adjoining rows, as well as the differences between the current and adjoining rows:

```
mysql> SELECT
      t, val,
      LAG(val)          OVER w AS 'lag',
      LEAD(val)         OVER w AS 'lead',
      val - LAG(val)    OVER w AS 'lag diff',
      val - LEAD(val)   OVER w AS 'lead diff'
FROM series
WINDOW w AS (ORDER BY t);
```

t	val	lag	lead	lag diff	lead diff
12:00:00	100	NULL	125	NULL	-25
13:00:00	125	100	132	25	-7
14:00:00	132	125	145	7	-13
15:00:00	145	132	140	13	5
16:00:00	140	145	150	-5	-10
17:00:00	150	140	200	10	-50
18:00:00	200	150	NULL	50	NULL

In the example, the `LAG()` and `LEAD()` calls use the default *N* and *default* values of 1 and `NULL`, respectively.

The first row shows what happens when there is no previous row for `LAG()`: The function returns the *default* value (in this case, `NULL`). The last row shows the same thing when there is no next row for `LEAD()`.

`LAG()` and `LEAD()` also serve to compute sums rather than differences. Consider this data set, which contains the first few numbers of the Fibonacci series:

```
mysql> SELECT n FROM fib ORDER BY n;
```

n
1
1
2
3
5
8

+-----+

The following query shows the `LAG()` and `LEAD()` values for the rows adjacent to the current row. It also uses those functions to add to the current row value the values from the preceding and following rows. The effect is to generate the next number in the Fibonacci series, and the next number after that:

```
mysql> SELECT
      n,
      LAG(n, 1, 0)      OVER w AS 'lag',
      LEAD(n, 1, 0)     OVER w AS 'lead',
      n + LAG(n, 1, 0) OVER w AS 'next_n',
      n + LEAD(n, 1, 0) OVER w AS 'next_next_n'
FROM fib
WINDOW w AS (ORDER BY n);
```

n	lag	lead	next_n	next_next_n
1	0	1	1	2
1	1	2	2	3
2	1	3	3	5
3	2	5	5	8
5	3	8	8	13
8	5	0	13	8

One way to generate the initial set of Fibonacci numbers is to use a recursive common table expression. For an example, see [Fibonacci Series Generation](#).

Beginning with MySQL 8.0.22, you cannot use a negative value for the rows argument of this function within a prepared statement.

- `LAST_VALUE(expr) [null_treatment] over_clause`

Returns the value of `expr` from the last row of the window frame.

`over_clause` is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

`null_treatment` is as described in the section introduction.

For an example, see the `FIRST_VALUE()` function description.

- `LEAD(expr [, N[, default]]) [null_treatment] over_clause`

Returns the value of `expr` from the row that leads (follows) the current row by `N` rows within its partition. If there is no such row, the return value is `default`. For example, if `N` is 3, the return value is `default` for the last two rows. If `N` or `default` are missing, the defaults are 1 and `NULL`, respectively.

`N` must be a literal nonnegative integer. If `N` is 0, `expr` is evaluated for the current row.

Beginning with MySQL 8.0.22, `N` cannot be `NULL`. In addition, it must now be an integer in the range 1 to 2^{63} , inclusive, in any of the following forms:

- an unsigned integer constant literal
- a positional parameter marker (?)
- a user-defined variable
- a local variable in a stored routine

`over_clause` is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

`null_treatment` is as described in the section introduction.

For an example, see the `LAG()` function description.

In MySQL 8.0.22 and later, use of a negative value for the rows argument of this function is not permitted in prepared statements.

- `NTH_VALUE(expr, N) [from_first_last] [null_treatment] over_clause`

Returns the value of `expr` from the `N`-th row of the window frame. If there is no such row, the return value is `NULL`.

`N` must be a literal positive integer.

`from_first_last` is part of the SQL standard, but the MySQL implementation permits only `FROM FIRST` (which is also the default). This means that calculations begin at the first row of the window. `FROM LAST` is parsed, but produces an error. To obtain the same effect as `FROM LAST` (begin calculations at the last row of the window), use `ORDER BY` to sort in reverse order.

`over_clause` is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).
`null_treatment` is as described in the section introduction.

For an example, see the `FIRST_VALUE()` function description.

In MySQL 8.0.22 and later, you cannot use `NULL` for the row argument of this function within a prepared statement.

- `NTILE(N) over_clause`

Divides a partition into `N` groups (buckets), assigns each row in the partition its bucket number, and returns the bucket number of the current row within its partition. For example, if `N` is 4, `NTILE()` divides rows into four buckets. If `N` is 100, `NTILE()` divides rows into 100 buckets.

`N` must be a literal positive integer. Bucket number return values range from 1 to `N`.

Beginning with MySQL 8.0.22, `N` cannot be `NULL`. In addition, it must be an integer in the range 1 to 2^{63} , inclusive, in any of the following forms:

- an unsigned integer constant literal
- a positional parameter marker (?)
- a user-defined variable
- a local variable in a stored routine

This function should be used with `ORDER BY` to sort partition rows into the desired order.

`over_clause` is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

The following query shows, for the set of values in the `val` column, the percentile values resulting from dividing the rows into two or four groups. For reference, the query also displays row numbers using `ROW_NUMBER()`:

```
mysql> SELECT
    val,
    ROW_NUMBER() OVER w AS 'row_number',
    NTILE(2)     OVER w AS 'ntile2',
    NTILE(4)     OVER w AS 'ntile4'
  FROM numbers
  WINDOW w AS (ORDER BY val);
```

val	row_number	ntile2	ntile4
1	1	1	1
1	2	1	1
2	3	1	1

3	4	1	2
3	5	1	2
3	6	2	3
4	7	2	3
4	8	2	4
5	9	2	4

Beginning with MySQL 8.0.22, the construct `NTILE(NULL)` is no longer permitted in prepared statements.

- `PERCENT_RANK() over_clause`

Returns the percentage of partition values less than the value in the current row, excluding the highest value. Return values range from 0 to 1 and represent the row relative rank, calculated as the result of this formula, where *rank* is the row rank and *rows* is the number of partition rows:

```
(rank - 1) / (rows - 1)
```

This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

over_clause is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

For an example, see the `CUME_DIST()` function description.

- `RANK() over_clause`

Returns the rank of the current row within its partition, with gaps. Peers are considered ties and receive the same rank. This function does not assign consecutive ranks to peer groups if groups of size greater than one exist; the result is noncontiguous rank numbers.

This function should be used with `ORDER BY` to sort partition rows into the desired order. Without `ORDER BY`, all rows are peers.

over_clause is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

The following query shows the difference between `RANK()`, which produces ranks with gaps, and `DENSE_RANK()`, which produces ranks without gaps. The query shows rank values for each member of a set of values in the `val` column, which contains some duplicates. `RANK()` assigns peers (the duplicates) the same rank value, and the next greater value has a rank higher by the number of peers minus one. `DENSE_RANK()` also assigns peers the same rank value, but the next higher value has a rank one greater. For reference, the query also displays row numbers using `ROW_NUMBER()`:

```
mysql> SELECT
    val,
    ROW_NUMBER() OVER w AS 'row_number',
    RANK() OVER w AS 'rank',
    DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);
```

val	row_number	rank	dense_rank
1	1	1	1
1	2	1	1
2	3	3	2
3	4	4	3
3	5	4	3
3	6	4	3
4	7	7	4
4	8	7	4
5	9	9	5

- `ROW_NUMBER() over_clause`

Returns the number of the current row within its partition. Rows numbers range from 1 to the number of partition rows.

`ORDER BY` affects the order in which rows are numbered. Without `ORDER BY`, row numbering is nondeterministic.

`ROW_NUMBER()` assigns peers different row numbers. To assign peers the same value, use `RANK()` or `DENSE_RANK()`. For an example, see the `RANK()` function description.

`over_clause` is as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#).

12.21.2 Window Function Concepts and Syntax

This section describes how to use window functions. Examples use the same sales information data set as found in the discussion of the `GROUPING()` function in [Section 12.20.2, “GROUP BY Modifiers”](#):

```
mysql> SELECT * FROM sales ORDER BY country, year, product;
```

year	country	product	profit
2000	Finland	Computer	1500
2000	Finland	Phone	100
2001	Finland	Phone	10
2000	India	Calculator	75
2000	India	Calculator	75
2000	India	Computer	1200
2000	USA	Calculator	75
2000	USA	Computer	1500
2001	USA	Calculator	50
2001	USA	Computer	1500
2001	USA	Computer	1200
2001	USA	TV	150
2001	USA	TV	100

A window function performs an aggregate-like operation on a set of query rows. However, whereas an aggregate operation groups query rows into a single result row, a window function produces a result for each query row:

- The row for which function evaluation occurs is called the current row.
- The query rows related to the current row over which function evaluation occurs comprise the window for the current row.

For example, using the sales information table, these two queries perform aggregate operations that produce a single global sum for all rows taken as a group, and sums grouped per country:

```
mysql> SELECT SUM(profit) AS total_profit
FROM sales;
```

total_profit
7535

```
mysql> SELECT country, SUM(profit) AS country_profit
FROM sales
GROUP BY country
ORDER BY country;
```

country	country_profit
Finland	1610
India	1350
USA	4575

By contrast, window operations do not collapse groups of query rows to a single output row. Instead, they produce a result for each row. Like the preceding queries, the following query uses `SUM()`, but this time as a window function:

```
mysql> SELECT
    year, country, product, profit,
    SUM(profit) OVER() AS total_profit,
    SUM(profit) OVER(PARTITION BY country) AS country_profit
FROM sales
ORDER BY country, year, product, profit;
```

year	country	product	profit	total_profit	country_profit
2000	Finland	Computer	1500	7535	1610
2000	Finland	Phone	100	7535	1610
2001	Finland	Phone	10	7535	1610
2000	India	Calculator	75	7535	1350
2000	India	Calculator	75	7535	1350
2000	India	Computer	1200	7535	1350
2000	USA	Calculator	75	7535	4575
2000	USA	Computer	1500	7535	4575
2001	USA	Calculator	50	7535	4575
2001	USA	Computer	1200	7535	4575
2001	USA	Computer	1500	7535	4575
2001	USA	TV	100	7535	4575
2001	USA	TV	150	7535	4575

Each window operation in the query is signified by inclusion of an `OVER` clause that specifies how to partition query rows into groups for processing by the window function:

- The first `OVER` clause is empty, which treats the entire set of query rows as a single partition. The window function thus produces a global sum, but does so for each row.
- The second `OVER` clause partitions rows by country, producing a sum per partition (per country). The function produces this sum for each partition row.

Window functions are permitted only in the select list and `ORDER BY` clause. Query result rows are determined from the `FROM` clause, after `WHERE`, `GROUP BY`, and `HAVING` processing, and windowing execution occurs before `ORDER BY`, `LIMIT`, and `SELECT DISTINCT`.

The `OVER` clause is permitted for many aggregate functions, which therefore can be used as window or nonwindow functions, depending on whether the `OVER` clause is present or absent:

```
AVG()
BIT_AND()
BIT_OR()
BIT_XOR()
COUNT()
JSON_ARRAYAGG()
JSON_OBJECTAGG()
MAX()
MIN()
STDDEV_POP(), STDDEV(), STD()
STDDEV_SAMP()
SUM()
VAR_POP(), VARIANCE()
VAR_SAMP()
```

For details about each aggregate function, see [Section 12.20.1, “Aggregate Function Descriptions”](#).

MySQL also supports nonaggregate functions that are used only as window functions. For these, the `OVER` clause is mandatory:

```
CUME_DIST()
DENSE_RANK()
FIRST_VALUE()
LAG()
```

```

LAST_VALUE ( )
LEAD ( )
NTH_VALUE ( )
NTILE ( )
PERCENT_RANK ( )
RANK ( )
ROW_NUMBER ( )

```

For details about each nonaggregate function, see [Section 12.21.1, “Window Function Descriptions”](#).

As an example of one of those nonaggregate window functions, this query uses `ROW_NUMBER ()`, which produces the row number of each row within its partition. In this case, rows are numbered per country. By default, partition rows are unordered and row numbering is nondeterministic. To sort partition rows, include an `ORDER BY` clause within the window definition. The query uses unordered and ordered partitions (the `row_num1` and `row_num2` columns) to illustrate the difference between omitting and including `ORDER BY`:

```

mysql> SELECT
    year, country, product, profit,
    ROW_NUMBER() OVER(PARTITION BY country) AS row_num1,
    ROW_NUMBER() OVER(PARTITION BY country ORDER BY year, product) AS row_num2
FROM sales;

```

year	country	product	profit	row_num1	row_num2
2000	Finland	Computer	1500	2	1
2000	Finland	Phone	100	1	2
2001	Finland	Phone	10	3	3
2000	India	Calculator	75	2	1
2000	India	Calculator	75	3	2
2000	India	Computer	1200	1	3
2000	USA	Calculator	75	5	1
2000	USA	Computer	1500	4	2
2001	USA	Calculator	50	2	3
2001	USA	Computer	1500	3	4
2001	USA	Computer	1200	7	5
2001	USA	TV	150	1	6
2001	USA	TV	100	6	7

As mentioned previously, to use a window function (or treat an aggregate function as a window function), include an `OVER` clause following the function call. The `OVER` clause has two forms:

```

over_clause:
    { OVER (window_spec) | OVER window_name }

```

Both forms define how the window function should process query rows. They differ in whether the window is defined directly in the `OVER` clause, or supplied by a reference to a named window defined elsewhere in the query:

- In the first case, the window specification appears directly in the `OVER` clause, between the parentheses.
- In the second case, `window_name` is the name for a window specification defined by a `WINDOW` clause elsewhere in the query. For details, see [Section 12.21.4, “Named Windows”](#).

For `OVER (window_spec)` syntax, the window specification has several parts, all optional:

```

window_spec:
    [window_name] [partition_clause] [order_clause] [frame_clause]

```

If `OVER ()` is empty, the window consists of all query rows and the window function computes a result using all rows. Otherwise, the clauses present within the parentheses determine which query rows are used to compute the function result and how they are partitioned and ordered:

- `window_name`: The name of a window defined by a `WINDOW` clause elsewhere in the query. If `window_name` appears by itself within the `OVER` clause, it completely defines the window. If

partitioning, ordering, or framing clauses are also given, they modify interpretation of the named window. For details, see [Section 12.21.4, “Named Windows”](#).

- *partition_clause*: A `PARTITION BY` clause indicates how to divide the query rows into groups. The window function result for a given row is based on the rows of the partition that contains the row. If `PARTITION BY` is omitted, there is a single partition consisting of all query rows.

Note

Partitioning for window functions differs from table partitioning. For information about table partitioning, see [Chapter 23, Partitioning](#).

partition_clause has this syntax:

```
partition_clause:
  PARTITION BY expr [, expr] ...
```

Standard SQL requires `PARTITION BY` to be followed by column names only. A MySQL extension is to permit expressions, not just column names. For example, if a table contains a `TIMESTAMP` column named `ts`, standard SQL permits `PARTITION BY ts` but not `PARTITION BY HOUR(ts)`, whereas MySQL permits both.

- *order_clause*: An `ORDER BY` clause indicates how to sort rows in each partition. Partition rows that are equal according to the `ORDER BY` clause are considered peers. If `ORDER BY` is omitted, partition rows are unordered, with no processing order implied, and all partition rows are peers.

order_clause has this syntax:

```
order_clause:
  ORDER BY expr [ASC|DESC] [, expr [ASC|DESC]] ...
```

Each `ORDER BY` expression optionally can be followed by `ASC` or `DESC` to indicate sort direction. The default is `ASC` if no direction is specified. `NULL` values sort first for ascending sorts, last for descending sorts.

An `ORDER BY` in a window definition applies within individual partitions. To sort the result set as a whole, include an `ORDER BY` at the query level.

- *frame_clause*: A frame is a subset of the current partition and the frame clause specifies how to define the subset. The frame clause has many subclauses of its own. For details, see [Section 12.21.3, “Window Function Frame Specification”](#).

12.21.3 Window Function Frame Specification

The definition of a window used with a window function can include a frame clause. A frame is a subset of the current partition and the frame clause specifies how to define the subset.

Frames are determined with respect to the current row, which enables a frame to move within a partition depending on the location of the current row within its partition. Examples:

- By defining a frame to be all rows from the partition start to the current row, you can compute running totals for each row.
- By defining a frame as extending `N` rows on either side of the current row, you can compute rolling averages.

The following query demonstrates the use of moving frames to compute running totals within each group of time-ordered `level` values, as well as rolling averages computed from the current row and the rows that immediately precede and follow it:

```
mysql> SELECT
  time, subject, val,
  SUM(val) OVER (PARTITION BY subject ORDER BY time
```

```

        ROWS UNBOUNDED PRECEDING)
    AS running_total,
    AVG(val) OVER (PARTITION BY subject ORDER BY time
        ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING)
    AS running_average
FROM observations;

```

time	subject	val	running_total	running_average
07:00:00	st113	10	10	9.5000
07:15:00	st113	9	19	14.6667
07:30:00	st113	25	44	18.0000
07:45:00	st113	20	64	22.5000
07:00:00	xh458	0	0	5.0000
07:15:00	xh458	10	10	5.0000
07:30:00	xh458	5	15	15.0000
07:45:00	xh458	30	45	20.0000
08:00:00	xh458	25	70	27.5000

For the `running_average` column, there is no frame row preceding the first one or following the last. In these cases, `AVG()` computes the average of the rows that are available.

Aggregate functions used as window functions operate on rows in the current row frame, as do these nonaggregate window functions:

```

FIRST_VALUE()
LAST_VALUE()
NTH_VALUE()

```

Standard SQL specifies that window functions that operate on the entire partition should have no frame clause. MySQL permits a frame clause for such functions but ignores it. These functions use the entire partition even if a frame is specified:

```

CUME_DIST()
DENSE_RANK()
LAG()
LEAD()
NTILE()
PERCENT_RANK()
RANK()
ROW_NUMBER()

```

The frame clause, if given, has this syntax:

```

frame_clause:
    frame_units frame_extent

frame_units:
    {ROWS | RANGE}

```

In the absence of a frame clause, the default frame depends on whether an `ORDER BY` clause is present, as described later in this section.

The `frame_units` value indicates the type of relationship between the current row and frame rows:

- **ROWS:** The frame is defined by beginning and ending row positions. Offsets are differences in row numbers from the current row number.
- **RANGE:** The frame is defined by rows within a value range. Offsets are differences in row values from the current row value.

The `frame_extent` value indicates the start and end points of the frame. You can specify just the start of the frame (in which case the current row is implicitly the end) or use `BETWEEN` to specify both frame endpoints:

```

frame_extent:
    {frame_start | frame_between}

```

```

frame_between:
    BETWEEN frame_start AND frame_end

frame_start, frame_end: {
    CURRENT ROW
    | UNBOUNDED PRECEDING
    | UNBOUNDED FOLLOWING
    | expr PRECEDING
    | expr FOLLOWING
}

```

With **BETWEEN** syntax, *frame_start* must not occur later than *frame_end*.

The permitted *frame_start* and *frame_end* values have these meanings:

- **CURRENT ROW**: For **ROWS**, the bound is the current row. For **RANGE**, the bound is the peers of the current row.
- **UNBOUNDED PRECEDING**: The bound is the first partition row.
- **UNBOUNDED FOLLOWING**: The bound is the last partition row.
- **expr PRECEDING**: For **ROWS**, the bound is *expr* rows before the current row. For **RANGE**, the bound is the rows with values equal to the current row value minus *expr*; if the current row value is **NULL**, the bound is the peers of the row.

For **expr PRECEDING** (and **expr FOLLOWING**), *expr* can be a **?** parameter marker (for use in a prepared statement), a nonnegative numeric literal, or a temporal interval of the form **INTERVAL val unit**. For **INTERVAL** expressions, *val* specifies nonnegative interval value, and *unit* is a keyword indicating the units in which the value should be interpreted. (For details about the permitted *units* specifiers, see the description of the **DATE_ADD()** function in [Section 12.7, “Date and Time Functions”](#).)

RANGE on a numeric or temporal *expr* requires **ORDER BY** on a numeric or temporal expression, respectively.

Examples of valid **expr PRECEDING** and **expr FOLLOWING** indicators:

```

10 PRECEDING
INTERVAL 5 DAY PRECEDING
5 FOLLOWING
INTERVAL '2:30' MINUTE_SECOND FOLLOWING

```

- **expr FOLLOWING**: For **ROWS**, the bound is *expr* rows after the current row. For **RANGE**, the bound is the rows with values equal to the current row value plus *expr*; if the current row value is **NULL**, the bound is the peers of the row.

For permitted values of *expr*, see the description of **expr PRECEDING**.

The following query demonstrates **FIRST_VALUE()**, **LAST_VALUE()**, and two instances of **NTH_VALUE()**:

```

mysql> SELECT
    time, subject, val,
    FIRST_VALUE(val) OVER w AS 'first',
    LAST_VALUE(val) OVER w AS 'last',
    NTH_VALUE(val, 2) OVER w AS 'second',
    NTH_VALUE(val, 4) OVER w AS 'fourth'
FROM observations
WINDOW w AS (PARTITION BY subject ORDER BY time
              ROWS UNBOUNDED PRECEDING);

```

time	subject	val	first	last	second	fourth
07:00:00	st113	10	10	10	NULL	NULL

07:15:00	st113	9	10	9	9	NULL	
07:30:00	st113	25	10	25	9	NULL	
07:45:00	st113	20	10	20	9	20	
07:00:00	xh458	0	0	0	NULL	NULL	
07:15:00	xh458	10	0	10	10	NULL	
07:30:00	xh458	5	0	5	10	NULL	
07:45:00	xh458	30	0	30	10	30	
08:00:00	xh458	25	0	25	10	30	

Each function uses the rows in the current frame, which, per the window definition shown, extends from the first partition row to the current row. For the `NTH_VALUE()` calls, the current frame does not always include the requested row; in such cases, the return value is `NULL`.

In the absence of a frame clause, the default frame depends on whether an `ORDER BY` clause is present:

- With `ORDER BY`: The default frame includes rows from the partition start through the current row, including all peers of the current row (rows equal to the current row according to the `ORDER BY` clause). The default is equivalent to this frame specification:

```
RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
```

- Without `ORDER BY`: The default frame includes all partition rows (because, without `ORDER BY`, all partition rows are peers). The default is equivalent to this frame specification:

```
RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING
```

Because the default frame differs depending on presence or absence of `ORDER BY`, adding `ORDER BY` to a query to get deterministic results may change the results. (For example, the values produced by `SUM()` might change.) To obtain the same results but ordered per `ORDER BY`, provide an explicit frame specification to be used regardless of whether `ORDER BY` is present.

The meaning of a frame specification can be nonobvious when the current row value is `NULL`. Assuming that to be the case, these examples illustrate how various frame specifications apply:

- `ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND 15 FOLLOWING`

The frame starts at `NULL` and stops at `NULL`, thus includes only rows with value `NULL`.

- `ORDER BY X ASC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING`

The frame starts at `NULL` and stops at the end of the partition. Because an `ASC` sort puts `NULL` values first, the frame is the entire partition.

- `ORDER BY X DESC RANGE BETWEEN 10 FOLLOWING AND UNBOUNDED FOLLOWING`

The frame starts at `NULL` and stops at the end of the partition. Because a `DESC` sort puts `NULL` values last, the frame is only the `NULL` values.

- `ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND UNBOUNDED FOLLOWING`

The frame starts at `NULL` and stops at the end of the partition. Because an `ASC` sort puts `NULL` values first, the frame is the entire partition.

- `ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 10 FOLLOWING`

The frame starts at `NULL` and stops at `NULL`, thus includes only rows with value `NULL`.

- `ORDER BY X ASC RANGE BETWEEN 10 PRECEDING AND 1 PRECEDING`

The frame starts at `NULL` and stops at `NULL`, thus includes only rows with value `NULL`.

- `ORDER BY X ASC RANGE BETWEEN UNBOUNDED PRECEDING AND 10 FOLLOWING`

The frame starts at the beginning of the partition and stops at rows with value `NULL`. Because an `ASC` sort puts `NULL` values first, the frame is only the `NULL` values.

12.21.4 Named Windows

Windows can be defined and given names by which to refer to them in `OVER` clauses. To do this, use a `WINDOW` clause. If present in a query, the `WINDOW` clause falls between the positions of the `HAVING` and `ORDER BY` clauses, and has this syntax:

```
WINDOW window_name AS (window_spec)
    [, window_name AS (window_spec)] ...
```

For each window definition, `window_name` is the window name, and `window_spec` is the same type of window specification as given between the parentheses of an `OVER` clause, as described in [Section 12.21.2, “Window Function Concepts and Syntax”](#):

```
window_spec:
    [window_name] [partition_clause] [order_clause] [frame_clause]
```

A `WINDOW` clause is useful for queries in which multiple `OVER` clauses would otherwise define the same window. Instead, you can define the window once, give it a name, and refer to the name in the `OVER` clauses. Consider this query, which defines the same window multiple times:

```
SELECT
    val,
    ROW_NUMBER() OVER (ORDER BY val) AS 'row_number',
    RANK() OVER (ORDER BY val) AS 'rank',
    DENSE_RANK() OVER (ORDER BY val) AS 'dense_rank'
FROM numbers;
```

The query can be written more simply by using `WINDOW` to define the window once and referring to the window by name in the `OVER` clauses:

```
SELECT
    val,
    ROW_NUMBER() OVER w AS 'row_number',
    RANK() OVER w AS 'rank',
    DENSE_RANK() OVER w AS 'dense_rank'
FROM numbers
WINDOW w AS (ORDER BY val);
```

A named window also makes it easier to experiment with the window definition to see the effect on query results. You need only modify the window definition in the `WINDOW` clause, rather than multiple `OVER` clause definitions.

If an `OVER` clause uses `OVER (window_name ...)` rather than `OVER window_name`, the named window can be modified by the addition of other clauses. For example, this query defines a window that includes partitioning, and uses `ORDER BY` in the `OVER` clauses to modify the window in different ways:

```
SELECT
    DISTINCT year, country,
    FIRST_VALUE(year) OVER (w ORDER BY year ASC) AS first,
    FIRST_VALUE(year) OVER (w ORDER BY year DESC) AS last
FROM sales
WINDOW w AS (PARTITION BY country);
```

An `OVER` clause can only add properties to a named window, not modify them. If the named window definition includes a partitioning, ordering, or framing property, the `OVER` clause that refers to the window name cannot also include the same kind of property or an error occurs:

- This construct is permitted because the window definition and the referring `OVER` clause do not contain the same kind of properties:

```
OVER (w ORDER BY country)
```

```
... WINDOW w AS (PARTITION BY country)
```

- This construct is not permitted because the `OVER` clause specifies `PARTITION BY` for a named window that already has `PARTITION BY`:

```
OVER (w PARTITION BY year)
... WINDOW w AS (PARTITION BY country)
```

The definition of a named window can itself begin with a `window_name`. In such cases, forward and backward references are permitted, but not cycles:

- This is permitted; it contains forward and backward references but no cycles:

```
WINDOW w1 AS (w2), w2 AS (), w3 AS (w1)
```

- This is not permitted because it contains a cycle:

```
WINDOW w1 AS (w2), w2 AS (w3), w3 AS (w1)
```

12.21.5 Window Function Restrictions

The SQL standard imposes a constraint on window functions that they cannot be used in `UPDATE` or `DELETE` statements to update rows. Using such functions in a subquery of these statements (to select rows) is permitted.

MySQL does not support these window function features:

- `DISTINCT` syntax for aggregate window functions.
- Nested window functions.
- Dynamic frame endpoints that depend on the value of the current row.

The parser recognizes these window constructs which nevertheless are not supported:

- The `GROUPS` frame units specifier is parsed, but produces an error. Only `ROWS` and `RANGE` are supported.
- The `EXCLUDE` clause for frame specification is parsed, but produces an error.
- `IGNORE NULLS` is parsed, but produces an error. Only `RESPECT NULLS` is supported.
- `FROM LAST` is parsed, but produces an error. Only `FROM FIRST` is supported.

12.22 Performance Schema Functions

As of MySQL 8.0.16, MySQL includes built-in SQL functions that format or retrieve Performance Schema data, and that may be used as equivalents for the corresponding `sys` schema stored functions. The built-in functions can be invoked in any schema and require no qualifier, unlike the `sys` functions, which require either a `sys.` schema qualifier or that `sys` be the current schema.

Table 12.27 Performance Schema Functions

Name	Description
<code>FORMAT_BYTES()</code> (introduced 8.0.16)	Convert byte count to value with units
<code>FORMAT_PICO_TIME()</code> (introduced 8.0.16)	Convert time in picoseconds to value with units
<code>PS_CURRENT_THREAD_ID()</code> (introduced 8.0.16)	Performance Schema thread ID for current thread
<code>PS_THREAD_ID()</code> (introduced 8.0.16)	Performance Schema thread ID for given thread

The built-in functions supersede the corresponding `sys` functions, which are deprecated and will be removed in a future MySQL version. Applications that use the `sys` functions should be adjusted to use the built-in functions instead, keeping in mind some minor differences between the `sys` functions and the built-in functions. For details about these differences, see the function descriptions in this section.

- `FORMAT_BYTES(count)`

Given a numeric byte count, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the number of bytes rounded to 2 decimal places and a minimum of 3 significant digits. Numbers less than 1024 bytes are represented as whole numbers and are not rounded.

The units indicator depends on the size of the byte-count argument as shown in the following table.

Argument Value	Result Units	Result Units Indicator
Up to 1023	bytes	bytes
Up to $1024^2 - 1$	kibibytes	KiB
Up to $1024^3 - 1$	mebibytes	MiB
Up to $1024^4 - 1$	gibibytes	GiB
Up to $1024^5 - 1$	tebibytes	TiB
Up to $1024^6 - 1$	pebibytes	PiB
1024^6 and up	exbibytes	EiB

```
mysql> SELECT FORMAT_BYTES(512), FORMAT_BYTES(18446644073709551615);
```

```
+-----+-----+
| FORMAT_BYTES(512) | FORMAT_BYTES(18446644073709551615) |
+-----+-----+
| 512 bytes        | 16.00 EiB                          |
+-----+-----+
```

`FORMAT_BYTES()` was added in MySQL 8.0.16. It may be used instead of the `sys` schema `format_bytes()` function, keeping in mind this difference:

- `FORMAT_BYTES()` uses the `EiB` units indicator. `sys.format_bytes()` does not.
- `FORMAT_PICO_TIME(time_val)`

Given a numeric Performance Schema latency or wait time in picoseconds, converts it to human-readable format and returns a string consisting of a value and a units indicator. The string contains the decimal time rounded to 2 decimal places and a minimum of 3 significant digits. Times under 1 nanosecond are represented as whole numbers and are not rounded.

The units indicator depends on the size of the time-value argument as shown in the following table.

Argument Value	Result Units	Result Units Indicator
Up to $10^3 - 1$	picoseconds	ps
Up to $10^6 - 1$	nanoseconds	ns
Up to $10^9 - 1$	microseconds	us
Up to $10^{12} - 1$	milliseconds	ms
Up to $60 \times 10^{12} - 1$	seconds	s
Up to $3.6 \times 10^{15} - 1$	minutes	min
Up to $8.64 \times 10^{16} - 1$	hours	h
8.64×10^{16} and up	days	d

```
mysql> SELECT FORMAT_PICO_TIME(3501), FORMAT_PICO_TIME(188732396662000);
```

FORMAT_PICO_TIME(3501)	FORMAT_PICO_TIME(188732396662000)
3.50 ns	3.15 min

`FORMAT_PICO_TIME()` was added in MySQL 8.0.16. It may be used instead of the `sys` schema `format_time()` function, keeping in mind these differences:

- To indicate minutes, `sys.format_time()` uses the `m` units indicator, whereas `FORMAT_PICO_TIME()` uses `min`.
- `sys.format_time()` uses the `w` (weeks) units indicator. `FORMAT_PICO_TIME()` does not.
- `PS_CURRENT_THREAD_ID()`

Returns a `BIGINT UNSIGNED` value representing the Performance Schema thread ID assigned to the current connection.

The thread ID return value is a value of the type given in the `THREAD_ID` column of Performance Schema tables.

Performance Schema configuration affects `PS_CURRENT_THREAD_ID()` the same way as for `PS_THREAD_ID()`. For details, see the description of that function.

```
mysql> SELECT PS_CURRENT_THREAD_ID();
+-----+
| PS_CURRENT_THREAD_ID() |
+-----+
| 52 |
+-----+
mysql> SELECT PS_THREAD_ID(CONNECTION_ID());
+-----+
| PS_THREAD_ID(CONNECTION_ID()) |
+-----+
| 52 |
+-----+
```

`PS_CURRENT_THREAD_ID()` was added in MySQL 8.0.16. It may be used as a shortcut for invoking the `sys` schema `ps_thread_id()` function with an argument of `NULL` or `CONNECTION_ID()`.

- `PS_THREAD_ID(connection_id)`

Given a connection ID, returns a `BIGINT UNSIGNED` value representing the Performance Schema thread ID assigned to the connection ID, or `NULL` if no thread ID exists for the connection ID. The latter can occur for threads that are not instrumented.

The connection ID argument is a value of the type given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

The thread ID return value is a value of the type given in the `THREAD_ID` column of Performance Schema tables.

Performance Schema configuration affects `PS_THREAD_ID()` operation as follows. (These remarks also apply to `PS_CURRENT_THREAD_ID()`.)

- Disabling the `thread_instrumentation` consumer disables statistics from being collected and aggregated at the thread level, but has no effect on `PS_THREAD_ID()`.
- If `performance_schema_max_thread_instances` is not 0, the Performance Schema allocates memory for thread statistics and assigns an internal ID to each thread for which instance memory is available. If there are threads for which

instance memory is not available, `PS_THREAD_ID()` returns `NULL`; in this case, `Performance_schema_thread_instances_lost` will be nonzero.

- If `performance_schema_max_thread_instances` is 0, the Performance Schema allocates no thread memory and `PS_THREAD_ID()` returns `NULL`.
- If the Performance Schema itself is disabled, `PS_THREAD_ID()` produces an error.

```
mysql> SELECT PS_THREAD_ID(6);
+-----+
| PS_THREAD_ID(6) |
+-----+
|                45 |
+-----+
```

`PS_THREAD_ID()` was added in MySQL 8.0.16. It may be used instead of the `sys` schema `ps_thread_id()` function, keeping in mind this difference:

- With an argument of `NULL`, `sys.ps_thread_id()` returns the thread ID for the current connection, whereas `PS_THREAD_ID()` returns `NULL`. To obtain the current connection thread ID, use `PS_CURRENT_THREAD_ID()` instead.

12.23 Internal Functions

Table 12.28 Internal Functions

Name	Description
<code>CAN_ACCESS_COLUMN()</code>	Internal use only
<code>CAN_ACCESS_DATABASE()</code>	Internal use only
<code>CAN_ACCESS_TABLE()</code>	Internal use only
<code>CAN_ACCESS_USER()</code> (introduced 8.0.22)	Internal use only
<code>CAN_ACCESS_VIEW()</code>	Internal use only
<code>GET_DD_COLUMN_PRIVILEGES()</code>	Internal use only
<code>GET_DD_CREATE_OPTIONS()</code>	Internal use only
<code>GET_DD_INDEX_SUB_PART_LENGTH()</code>	Internal use only
<code>INTERNAL_AUTO_INCREMENT()</code>	Internal use only
<code>INTERNAL_AVG_ROW_LENGTH()</code>	Internal use only
<code>INTERNAL_CHECK_TIME()</code>	Internal use only
<code>INTERNAL_CHECKSUM()</code>	Internal use only
<code>INTERNAL_DATA_FREE()</code>	Internal use only
<code>INTERNAL_DATA_LENGTH()</code>	Internal use only
<code>INTERNAL_DD_CHAR_LENGTH()</code>	Internal use only
<code>INTERNAL_GET_COMMENT_OR_ERROR()</code>	Internal use only
<code>INTERNAL_GET_ENABLED_ROLE_JSON()</code> (introduced 8.0.19)	Internal use only
<code>INTERNAL_GET_HOSTNAME()</code> (introduced 8.0.19)	Internal use only
<code>INTERNAL_GET_USERNAME()</code> (introduced 8.0.19)	Internal use only
<code>INTERNAL_GET_VIEW_WARNING_OR_ERROR()</code>	Internal use only
<code>INTERNAL_INDEX_COLUMN_CARDINALITY()</code>	Internal use only

Name	Description
<code>INTERNAL_INDEX_LENGTH ()</code>	Internal use only
<code>INTERNAL_IS_ENABLED_ROLE ()</code> (introduced 8.0.19)	Internal use only
<code>INTERNAL_IS_MANDATORY_ROLE ()</code> (introduced 8.0.19)	Internal use only
<code>INTERNAL_KEYS_DISABLED ()</code>	Internal use only
<code>INTERNAL_MAX_DATA_LENGTH ()</code>	Internal use only
<code>INTERNAL_TABLE_ROWS ()</code>	Internal use only
<code>INTERNAL_UPDATE_TIME ()</code>	Internal use only

The functions listed in this section are intended only for internal use by the server. Attempts by users to invoke them result in an error.

12.24 Miscellaneous Functions

Table 12.29 Miscellaneous Functions

Name	Description
<code>ANY_VALUE()</code>	Suppress <code>ONLY_FULL_GROUP_BY</code> value rejection
<code>BIN_TO_UUID()</code>	Convert binary UUID to string
<code>DEFAULT()</code>	Return the default value for a table column
<code>GROUPING()</code>	Distinguish super-aggregate <code>ROLLUP</code> rows from regular rows
<code>INET_ATON()</code>	Return the numeric value of an IP address
<code>INET_NTOA()</code>	Return the IP address from a numeric value
<code>INET6_ATON()</code>	Return the numeric value of an IPv6 address
<code>INET6_NTOA()</code>	Return the IPv6 address from a numeric value
<code>IS_IPV4()</code>	Whether argument is an IPv4 address
<code>IS_IPV4_COMPAT()</code>	Whether argument is an IPv4-compatible address
<code>IS_IPV4_MAPPED()</code>	Whether argument is an IPv4-mapped address
<code>IS_IPV6()</code>	Whether argument is an IPv6 address
<code>IS_UUID()</code>	Whether argument is a valid UUID
<code>MASTER_POS_WAIT()</code>	Block until the replica has read and applied all updates up to the specified position
<code>NAME_CONST()</code>	Cause the column to have the given name
<code>SLEEP()</code>	Sleep for a number of seconds
<code>UUID()</code>	Return a Universal Unique Identifier (UUID)
<code>UUID_SHORT()</code>	Return an integer-valued universal identifier
<code>UUID_TO_BIN()</code>	Convert string UUID to binary
<code>VALUES()</code>	Define the values to be used during an <code>INSERT</code>

- `ANY_VALUE(arg)`

This function is useful for `GROUP BY` queries when the `ONLY_FULL_GROUP_BY` SQL mode is enabled, for cases when MySQL rejects a query that you know is valid for reasons that MySQL cannot determine. The function return value and type are the same as the return value and type of its argument, but the function result is not checked for the `ONLY_FULL_GROUP_BY` SQL mode.

For example, if `name` is a nonindexed column, the following query fails with `ONLY_FULL_GROUP_BY` enabled:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP
BY clause and contains nonaggregated column 'mydb.t.address' which
is not functionally dependent on columns in GROUP BY clause; this
is incompatible with sql_mode=only_full_group_by
```

The failure occurs because `address` is a nonaggregated column that is neither named among `GROUP BY` columns nor functionally dependent on them. As a result, the `address` value for rows within each `name` group is nondeterministic. There are multiple ways to cause MySQL to accept the query:

- Alter the table to make `name` a primary key or a unique `NOT NULL` column. This enables MySQL to determine that `address` is functionally dependent on `name`; that is, `address` is uniquely determined by `name`. (This technique is inapplicable if `NULL` must be permitted as a valid `name` value.)
- Use `ANY_VALUE()` to refer to `address`:

```
SELECT name, ANY_VALUE(address), MAX(age) FROM t GROUP BY name;
```

In this case, MySQL ignores the nondeterminism of `address` values within each `name` group and accepts the query. This may be useful if you simply do not care which value of a nonaggregated column is chosen for each group. `ANY_VALUE()` is not an aggregate function, unlike functions such as `SUM()` or `COUNT()`. It simply acts to suppress the test for nondeterminism.

- Disable `ONLY_FULL_GROUP_BY`. This is equivalent to using `ANY_VALUE()` with `ONLY_FULL_GROUP_BY` enabled, as described in the previous item.

`ANY_VALUE()` is also useful if functional dependence exists between columns but MySQL cannot determine it. The following query is valid because `age` is functionally dependent on the grouping column `age-1`, but MySQL cannot tell that and rejects the query with `ONLY_FULL_GROUP_BY` enabled:

```
SELECT age FROM t GROUP BY age-1;
```

To cause MySQL to accept the query, use `ANY_VALUE()`:

```
SELECT ANY_VALUE(age) FROM t GROUP BY age-1;
```

`ANY_VALUE()` can be used for queries that refer to aggregate functions in the absence of a `GROUP BY` clause:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): In aggregated query without GROUP BY, expression
#1 of SELECT list contains nonaggregated column 'mydb.t.name'; this
is incompatible with sql_mode=only_full_group_by
```

Without `GROUP BY`, there is a single group and it is nondeterministic which `name` value to choose for the group. `ANY_VALUE()` tells MySQL to accept the query:

```
SELECT ANY_VALUE(name), MAX(age) FROM t;
```

It may be that, due to some property of a given data set, you know that a selected nonaggregated column is effectively functionally dependent on a `GROUP BY` column. For example, an application may enforce uniqueness of one column with respect to another. In this case, using `ANY_VALUE()` for the effectively functionally dependent column may make sense.

For additional discussion, see [Section 12.20.3, “MySQL Handling of GROUP BY”](#).

- `BIN_TO_UUID(binary_uuid)`, `BIN_TO_UUID(binary_uuid, swap_flag)`

`BIN_TO_UUID()` is the inverse of `UUID_TO_BIN()`. It converts a binary UUID to a string UUID and returns the result. The binary value should be a UUID as a `VARBINARY(16)` value. The return value is a `utf8` string of five hexadecimal numbers separated by dashes. (For details about this format,

see the [UUID\(\)](#) function description.) If the UUID argument is [NULL](#), the return value is [NULL](#). If any argument is invalid, an error occurs.

[BIN_TO_UUID\(\)](#) takes one or two arguments:

- The one-argument form takes a binary UUID value. The UUID value is assumed not to have its time-low and time-high parts swapped. The string result is in the same order as the binary argument.
- The two-argument form takes a binary UUID value and a swap-flag value:
 - If *swap_flag* is 0, the two-argument form is equivalent to the one-argument form. The string result is in the same order as the binary argument.
 - If *swap_flag* is 1, the UUID value is assumed to have its time-low and time-high parts swapped. These parts are swapped back to their original position in the result value.

For usage examples and information about time-part swapping, see the [UUID_TO_BIN\(\)](#) function description.

- [DEFAULT\(col_name\)](#)

Returns the default value for a table column. An error results if the column has no default value.

The use of [DEFAULT\(col_name\)](#) to specify the default value for a named column is permitted only for columns that have a literal default value, not for columns that have an expression default value.

```
mysql> UPDATE t SET i = DEFAULT(i)+1 WHERE id < 100;
```

- [FORMAT\(X,D\)](#)

Formats the number *X* to a format like '#,###,###.##', rounded to *D* decimal places, and returns the result as a string. For details, see [Section 12.8, “String Functions and Operators”](#).

- [GROUPING\(expr \[, expr\] ...\)](#)

For [GROUP BY](#) queries that include a [WITH ROLLUP](#) modifier, the [ROLLUP](#) operation produces super-aggregate output rows where [NULL](#) represents the set of all values. The [GROUPING\(\)](#) function enables you to distinguish [NULL](#) values for super-aggregate rows from [NULL](#) values in regular grouped rows.

[GROUPING\(\)](#) is permitted only in the select list or [HAVING](#) clause.

Each argument to [GROUPING\(\)](#) must be an expression that exactly matches an expression in the [GROUP BY](#) clause. The expression cannot be a positional specifier. For each expression, [GROUPING\(\)](#) produces 1 if the expression value in the current row is a [NULL](#) representing a super-aggregate value. Otherwise, [GROUPING\(\)](#) produces 0, indicating that the expression value is a [NULL](#) for a regular result row or is not [NULL](#).

Suppose that table `t1` contains these rows, where [NULL](#) indicates something like “other” or “unknown”:

```
mysql> SELECT * FROM t1;
+-----+-----+-----+
| name | size | quantity |
+-----+-----+-----+
| ball | small | 10 |
| ball | large | 20 |
| ball | NULL | 5 |
| hoop | small | 15 |
| hoop | large | 5 |
| hoop | NULL | 3 |
```

A summary of the table without `WITH ROLLUP` looks like this:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size;
```

name	size	quantity
ball	small	10
ball	large	20
ball	NULL	5
hoop	small	15
hoop	large	5
hoop	NULL	3

The result contains `NULL` values, but those do not represent super-aggregate rows because the query does not include `WITH ROLLUP`.

Adding `WITH ROLLUP` produces super-aggregate summary rows containing additional `NULL` values. However, without comparing this result to the previous one, it is not easy to see which `NULL` values occur in super-aggregate rows and which occur in regular grouped rows:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

name	size	quantity
ball	NULL	5
ball	large	20
ball	small	10
ball	NULL	35
hoop	NULL	3
hoop	large	5
hoop	small	15
hoop	NULL	23
NULL	NULL	58

To distinguish `NULL` values in super-aggregate rows from those in regular grouped rows, use `GROUPING()`, which returns 1 only for super-aggregate `NULL` values:

```
mysql> SELECT
name, size, SUM(quantity) AS quantity,
GROUPING(name) AS grp_name,
GROUPING(size) AS grp_size
FROM t1
GROUP BY name, size WITH ROLLUP;
```

name	size	quantity	grp_name	grp_size
ball	NULL	5	0	0
ball	large	20	0	0
ball	small	10	0	0
ball	NULL	35	0	1
hoop	NULL	3	0	0
hoop	large	5	0	0
hoop	small	15	0	0
hoop	NULL	23	0	1
NULL	NULL	58	1	1

Common uses for `GROUPING()`:

- Substitute a label for super-aggregate `NULL` values:

```
mysql> SELECT
    IF(GROUPING(name) = 1, 'All items', name) AS name,
    IF(GROUPING(size) = 1, 'All sizes', size) AS size,
    SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP;
```

name	size	quantity
ball	NULL	5
ball	large	20
ball	small	10
ball	All sizes	35
hoop	NULL	3
hoop	large	5
hoop	small	15
hoop	All sizes	23
All items	All sizes	58

- Return only super-aggregate lines by filtering out the regular grouped lines:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
FROM t1
GROUP BY name, size WITH ROLLUP
HAVING GROUPING(name) = 1 OR GROUPING(size) = 1;
```

name	size	quantity
ball	NULL	35
hoop	NULL	23
NULL	NULL	58

`GROUPING()` permits multiple expression arguments. In this case, the `GROUPING()` return value represents a bitmask combined from the results for each expression, where the lowest-order bit corresponds to the result for the rightmost expression. For example, with three expression arguments, `GROUPING(expr1, expr2, expr3)` is evaluated like this:

```
result for GROUPING(expr3)
+ result for GROUPING(expr2) << 1
+ result for GROUPING(expr1) << 2
```

The following query shows how `GROUPING()` results for single arguments combine for a multiple-argument call to produce a bitmask value:

```
mysql> SELECT
    name, size, SUM(quantity) AS quantity,
    GROUPING(name) AS grp_name,
    GROUPING(size) AS grp_size,
    GROUPING(name, size) AS grp_all
FROM t1
GROUP BY name, size WITH ROLLUP;
```

name	size	quantity	grp_name	grp_size	grp_all
ball	NULL	5	0	0	0
ball	large	20	0	0	0
ball	small	10	0	0	0
ball	NULL	35	0	1	1
hoop	NULL	3	0	0	0
hoop	large	5	0	0	0
hoop	small	15	0	0	0
hoop	NULL	23	0	1	1

NULL	NULL	58	1	1	3
+	+	+	+	+	+

With multiple expression arguments, the `GROUPING()` return value is nonzero if any expression represents a super-aggregate value. Multiple-argument `GROUPING()` syntax thus provides a simpler way to write the earlier query that returned only super-aggregate rows, by using a single multiple-argument `GROUPING()` call rather than multiple single-argument calls:

```
mysql> SELECT name, size, SUM(quantity) AS quantity
      FROM t1
      GROUP BY name, size WITH ROLLUP
      HAVING GROUPING(name, size) <> 0;
```

name	size	quantity
ball	NULL	35
hoop	NULL	23
NULL	NULL	58

Use of `GROUPING()` is subject to these limitations:

- Do not use subquery `GROUP BY` expressions as `GROUPING()` arguments because matching might fail. For example, matching fails for this query:

```
mysql> SELECT GROUPING((SELECT MAX(name) FROM t1))
      FROM t1
      GROUP BY (SELECT MAX(name) FROM t1) WITH ROLLUP;
ERROR 3580 (HY000): Argument #1 of GROUPING function is not in GROUP BY
```

- `GROUP BY` literal expressions should not be used within a `HAVING` clause as `GROUPING()` arguments. Due to differences between when the optimizer evaluates `GROUP BY` and `HAVING`, matching may succeed but `GROUPING()` evaluation does not produce the expected result. Consider this query:

```
SELECT a AS f1, 'w' AS f2
FROM t
GROUP BY f1, f2 WITH ROLLUP
HAVING GROUPING(f2) = 1;
```

`GROUPING()` is evaluated earlier for the literal constant expression than for the `HAVING` clause as a whole and returns 0. To check whether a query such as this is affected, use `EXPLAIN` and look for `Impossible having` in the `Extra` column.

For more information about `WITH ROLLUP` and `GROUPING()`, see [Section 12.20.2, “GROUP BY Modifiers”](#).

- `INET_ATON(expr)`

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address in network byte order (big endian). `INET_ATON()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_ATON('10.0.5.9');
```

```
-> 167773449
```

For this example, the return value is calculated as $10 \times 256^3 + 0 \times 256^2 + 5 \times 256 + 9$.

`INET_ATON()` may or may not return a non-`NULL` result for short-form IP addresses (such as `'127.1'` as a representation of `'127.0.0.1'`). Because of this, `INET_ATON()` should not be used for such addresses.

Note

To store values generated by `INET_ATON()`, use an `INT UNSIGNED` column rather than `INT`, which is signed. If you use a signed column, values corresponding to IP addresses for which the first octet is greater than 127 cannot be stored correctly. See [Section 11.1.7, “Out-of-Range and Overflow Handling”](#).

- `INET_NTOA(expr)`

Given a numeric IPv4 network address in network byte order, returns the dotted-quad string representation of the address as a string in the connection character set. `INET_NTOA()` returns `NULL` if it does not understand its argument.

```
mysql> SELECT INET_NTOA(167773449);
-> '10.0.5.9'
```

- `INET6_ATON(expr)`

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address in network byte order (big endian). Because numeric-format IPv6 addresses require more bytes than the largest integer type, the representation returned by this function has the `VARBINARY` data type: `VARBINARY(16)` for IPv6 addresses and `VARBINARY(4)` for IPv4 addresses. If the argument is not a valid address, `INET6_ATON()` returns `NULL`.

The following examples use `HEX()` to display the `INET6_ATON()` result in printable form:

```
mysql> SELECT HEX(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'FDFE00000000000005A55CAFFFEFA9089'
mysql> SELECT HEX(INET6_ATON('10.0.5.9'));
-> '0A000509'
```

`INET6_ATON()` observes several constraints on valid arguments. These are given in the following list along with examples.

- A trailing zone ID is not permitted, as in `fe80::3%1` or `fe80::3%eth0`.
- A trailing network mask is not permitted, as in `2001:45f:3:ba::/64` or `198.51.100.0/24`.
- For values representing IPv4 addresses, only classless addresses are supported. Classful addresses such as `198.51.1` are rejected. A trailing port number is not permitted, as in `198.51.100.2:8080`. Hexadecimal numbers in address components are not permitted, as in `198.0xa0.1.2`. Octal numbers are not supported: `198.51.010.1` is treated as `198.51.10.1`, not `198.51.8.1`. These IPv4 constraints also apply to IPv6 addresses that have IPv4 address parts, such as IPv4-compatible or IPv4-mapped addresses.

To convert an IPv4 address `expr` represented in numeric form as an `INT` value to an IPv6 address represented in numeric form as a `VARBINARY` value, use this expression:

```
INET6_ATON( INET_NTOA(expr) )
```

For example:

```
mysql> SELECT HEX(INET6_ATON(INET_NTOA(167773449)));
-> '0A000509'
```

- `INET6_NTOA(expr)`

Given an IPv6 or IPv4 network address represented in numeric form as a binary string, returns the string representation of the address as a string in the connection character set. If the argument is not a valid address, `INET6_NTOA()` returns `NULL`.

`INET6_NTOA()` has these properties:

- It does not use operating system functions to perform conversions, thus the output string is platform independent.
- The return string has a maximum length of 39 (4 x 8 + 7). Given this statement:

```
CREATE TABLE t AS SELECT INET6_NTOA(expr) AS c1;
```

The resulting table would have this definition:

```
CREATE TABLE t (c1 VARCHAR(39) CHARACTER SET utf8 DEFAULT NULL);
```

- The return string uses lowercase letters for IPv6 addresses.

```
mysql> SELECT INET6_NTOA(INET6_ATON('fdfe::5a55:caff:fefa:9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(INET6_ATON('10.0.5.9'));
-> '10.0.5.9'

mysql> SELECT INET6_NTOA(UNHEX('FDFE0000000000005A55CAFFFEFA9089'));
-> 'fdfe::5a55:caff:fefa:9089'
mysql> SELECT INET6_NTOA(UNHEX('0A000509'));
-> '10.0.5.9'
```

- `IS_IPV4(expr)`

Returns 1 if the argument is a valid IPv4 address specified as a string, 0 otherwise.

```
mysql> SELECT IS_IPV4('10.0.5.9'), IS_IPV4('10.0.5.256');
-> 1, 0
```

For a given argument, if `IS_IPV4()` returns 1, `INET_ATON()` (and `INET6_ATON()`) will return non-`NULL`. The converse statement is not true: In some cases, `INET_ATON()` returns non-`NULL` when `IS_IPV4()` returns 0.

As implied by the preceding remarks, `IS_IPV4()` is more strict than `INET_ATON()` about what constitutes a valid IPv4 address, so it may be useful for applications that need to perform strong checks against invalid values. Alternatively, use `INET6_ATON()` to convert IPv4 addresses to internal form and check for a `NULL` result (which indicates an invalid address). `INET6_ATON()` is equally strong as `IS_IPV4()` about checking IPv4 addresses.

- `IS_IPV4_COMPAT(expr)`

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-compatible IPv6 address, 0 otherwise. IPv4-compatible addresses have the form `::ipv4_address`.

```
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.5.9'));
-> 1
mysql> SELECT IS_IPV4_COMPAT(INET6_ATON('::ffff:10.0.5.9'));
-> 0
```

The IPv4 part of an IPv4-compatible address can also be represented using hexadecimal notation. For example, `198.51.100.1` has this raw hexadecimal value:

```
mysql> SELECT HEX(INET6_ATON('198.51.100.1'));
```

```
-> 'C6336401'
```

Expressed in IPv4-compatible form, `::198.51.100.1` is equivalent to `::c0a8:0001` or (without leading zeros) `::c0a8:1`

```
mysql> SELECT
->   IS_IPV4_COMPAT(INET6_ATON('::198.51.100.1')),
->   IS_IPV4_COMPAT(INET6_ATON('::c0a8:0001')),
->   IS_IPV4_COMPAT(INET6_ATON('::c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV4_MAPPED(expr)`

This function takes an IPv6 address represented in numeric form as a binary string, as returned by `INET6_ATON()`. It returns 1 if the argument is a valid IPv4-mapped IPv6 address, 0 otherwise. IPv4-mapped addresses have the form `::ffff:ipv4_address`.

```
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.5.9'));
-> 0
mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with `IS_IPV4_COMPAT()` the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```
mysql> SELECT
->   IS_IPV4_MAPPED(INET6_ATON('::ffff:198.51.100.1')),
->   IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
->   IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV6(expr)`

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` will return non-NULL.

- `IS_UUID(string_uuid)`

Returns 1 if the argument is a valid string-format UUID, 0 if the argument is not a valid UUID, and NULL if the argument is NULL.

“Valid” means that the value is in a format that can be parsed. That is, it has the correct length and contains only the permitted characters (hexadecimal digits in any lettercase and, optionally, dashes and curly braces). This format is most common:

```
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee
```

These other formats are also permitted:

```
aaaaaaaaabbbbccccdddeeeeeeeeeeee
{aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee}
```

For the meanings of fields within the value, see the `UUID()` function description.

```
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db');
+-----+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db') |
+-----+
|                                     1 |
+-----+
mysql> SELECT IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB');
+-----+
```

```

| IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB') |
+-----+
| 1 |
+-----+
mysql> SELECT IS_UUID('6ccd780cbaba102695645b8c656024db');
+-----+
| IS_UUID('6ccd780cbaba102695645b8c656024db') |
+-----+
| 1 |
+-----+
mysql> SELECT IS_UUID('{6ccd780c-baba-1026-9564-5b8c656024db}');
+-----+
| IS_UUID('{6ccd780c-baba-1026-9564-5b8c656024db}') |
+-----+
| 1 |
+-----+
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c6560');
+-----+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c6560') |
+-----+
| 0 |
+-----+
mysql> SELECT IS_UUID(RAND());
+-----+
| IS_UUID(RAND()) |
+-----+
| 0 |
+-----+

```

- `MASTER_POS_WAIT(log_name, log_pos[, timeout][, channel])`

This function is useful for control of source/replica synchronization. It blocks until the replica has read and applied all updates up to the specified position in the source's binary log. The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns `NULL` if the replication SQL thread is not started, the replica's source information is not initialized, the arguments are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the replication SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the replica is past the specified position, the function returns immediately.

On a multithreaded replica, the function waits until expiry of the limit set by the `slave_checkpoint_group` or `slave_checkpoint_period` system variable, when the checkpoint operation is called to update the status of the replica. Depending on the setting for the system variables, the function might therefore return some time after the specified position was reached.

If binary log transaction compression is in use and the transaction payload at the specified position is compressed (as a `Transaction_payload_event`), the function waits until the whole transaction has been read and applied, and the positions have updated.

If a `timeout` value is specified, `MASTER_POS_WAIT()` stops waiting when `timeout` seconds have elapsed. `timeout` must be greater than 0; a zero or negative `timeout` means no timeout.

The optional `channel` value enables you to name which replication channel the function applies to. See [Section 17.2.2, "Replication Channels"](#) for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `NAME_CONST(name, value)`

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```

mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+

```

```
+-----+
|      14      |
+-----+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in [Section 24.7, “Stored Program Binary Logging”](#). You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+-----+
| myname |
+-----+
|      14      |
+-----+
1 row in set (0.00 sec)
```

See [Section 13.2.10, “SELECT Statement”](#), for more information about column aliases.

- `SLEEP(duration)`

Sleeps (pauses) for the number of seconds given by the *duration* argument, then returns 0. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

When sleep returns normally (without interruption), it returns 0:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|            0 |
+-----+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|            1 |
+-----+
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|            1 |
+-----+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000);
```

```
ERROR 3024 (HY000): Query execution was interrupted, maximum statement
execution time exceeded
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `UUID()`

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique Identifier (UUID) URN Namespace” (<http://www.ietf.org/rfc/rfc4122.txt>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

Warning

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

`UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD, Linux, and Windows. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

To convert between string and binary UUID values, use the `UUID_TO_BIN()` and `BIN_TO_UUID()` functions. To check whether a string is a valid UUID value, use the `IS_UUID()` function.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `UUID_SHORT()`

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by `UUID_SHORT()` differ from the string-format 128-bit identifiers returned by the `UUID()` function and

have different uniqueness properties. The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` value of the current server is between 0 and 255 and is unique among your set of source and replica servers
- You do not set back the system time for your server host between `mysqld` restarts
- You invoke `UUID_SHORT()` on average fewer than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

Note

`UUID_SHORT()` does not work with statement-based replication.

- `UUID_TO_BIN(string_uuid), UUID_TO_BIN(string_uuid, swap_flag)`

Converts a string UUID to a binary UUID and returns the result. (The `IS_UUID()` function description lists the permitted string UUID formats.) The return binary UUID is a `VARBINARY(16)` value. If the UUID argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

`UUID_TO_BIN()` takes one or two arguments:

- The one-argument form takes a string UUID value. The binary result is in the same order as the string argument.
- The two-argument form takes a string UUID value and a flag value:
 - If `swap_flag` is 0, the two-argument form is equivalent to the one-argument form. The binary result is in the same order as the string argument.
 - If `swap_flag` is 1, the format of the return value differs: The time-low and time-high parts (the first and third groups of hexadecimal digits, respectively) are swapped. This moves the more rapidly varying part to the right and can improve indexing efficiency if the result is stored in an indexed column.

Time-part swapping assumes the use of UUID version 1 values, such as are generated by the `UUID()` function. For UUID values produced by other means that do not follow version 1 format, time-part swapping provides no benefit. For details about version 1 format, see the `UUID()` function description.

Suppose that you have the following string UUID value:

```
mysql> SET @uuid = '6ccd780c-baba-1026-9564-5b8c656024db';
```

To convert the string UUID to binary with or without time-part swapping, use `UUID_TO_BIN()`:

```
mysql> SELECT HEX(UUID_TO_BIN(@uuid));
+-----+
| HEX(UUID_TO_BIN(@uuid)) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
```

```

+-----+
mysql> SELECT HEX(UUID_TO_BIN(@uuid, 0));
+-----+
| HEX(UUID_TO_BIN(@uuid, 0)) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
mysql> SELECT HEX(UUID_TO_BIN(@uuid, 1));
+-----+
| HEX(UUID_TO_BIN(@uuid, 1)) |
+-----+
| 1026BABA6CCD780C95645B8C656024DB |
+-----+

```

To convert a binary UUID returned by `UUID_TO_BIN()` to a string UUID, use `BIN_TO_UUID()`. If you produce a binary UUID by calling `UUID_TO_BIN()` with a second argument of 1 to swap time parts, you should also pass a second argument of 1 to `BIN_TO_UUID()` to unswap the time parts when converting the binary UUID back to a string UUID:

```

mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid));
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid)) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),0);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),0) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+

```

If the use of time-part swapping is not the same for the conversion in both directions, the original UUID will not be recovered properly:

```

mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1) |
+-----+
| baba1026-780c-6ccd-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),0);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),0) |
+-----+
| 1026baba-6ccd-780c-9564-5b8c656024db |
+-----+

```

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See [Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
```

```
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

Important

This usage is deprecated in MySQL 8.0.20, and is subject to removal in a future release of MySQL. Use a row alias, or row and column aliases, instead. See [Section 13.2.6.2, “INSERT ... ON DUPLICATE KEY UPDATE Statement”](#), for more information and examples.

12.25 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree of control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact value rather than as an approximation, and summing it 10,000 times produces a result of exactly `1`, not a value that is merely “close” to 1.
- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see [Section 5.1.11, “Server SQL Modes”](#).

12.25.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and `DECIMAL` types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

12.25.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of `DECIMAL` columns

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments are as follows:

- *M* is the maximum number of digits (the precision). It has a range of 1 to 65.
- *D* is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than *M*.

If *D* is omitted, the default is 0. If *M* is omitted, the default is 10.

The maximum value of 65 for *M* means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before. (There is also a limit on how long the text of `DECIMAL` literals can be; see [Section 12.25.3, “Expression Handling”](#).)

Values for `DECIMAL` columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1–2	1
3–4	2
5–6	3
7–9	4

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

`DECIMAL` columns do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored.

`DECIMAL` columns do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column permits up to *M* - *D* digits to the left of the decimal point.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly* *M* digits. For `DECIMAL(M,D)`, the standard requires a precision of at least *M* digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly *M* digits.

For a full explanation of the internal format of `DECIMAL` values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

12.25.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using **DECIMAL** exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as **BIGINT** (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.1.11, “Server SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (**DECIMAL** or integer), it is inserted with its exact value if it is within the column range and precision.

If the value has too many digits in the fractional part, rounding occurs and a note is generated. Rounding is done as described in [Section 12.25.4, “Rounding Behavior”](#). Truncation due to rounding of the fractional part is not an error, even in strict mode.

If the value has too many digits in the integer part, it is too large (out of range) and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

For **DECIMAL** literals, in addition to the precision limit of 65 digits, there is a limit on how long the text of the literal can be. If the value exceeds approximately 80 characters, unexpected results can occur. For example:

[illegible]

```
| 999999999999.99 |
+-----+
1 row in set, 2 warnings (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1292 | Truncated incorrect DECIMAL value: '20' |
| Warning | 1264 | Out of range value for column 'val' at row 1 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

sql_mode Value	Result
' ' (Default)	No warning, no error; <code>i</code> is set to <code>NULL</code> .
strict	No warning, no error; <code>i</code> is set to <code>NULL</code> .
<code>ERROR_FOR_DIVISION_BY_ZERO</code>	Warning, no error; <code>i</code> is set to <code>NULL</code> .
strict, <code>ERROR_FOR_DIVISION_BY_ZERO</code>	Error condition; no row is inserted.

12.25.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other

words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative. (In other words, it is rounded toward zero.)

- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with a fractional part exactly half way between two integers is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1265 | Data truncated for column 'd' at row 1    |
| Note  | 1265 | Data truncated for column 'd' at row 2    |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT d FROM t;
+-----+
| d    |
+-----+
| 3    |
| 3    |
+-----+
2 rows in set (0.00 sec)
```

The `SHOW WARNINGS` statement displays the notes that are generated by truncation due to rounding of the fractional part. Such truncation is not an error, even in strict SQL mode (see [Section 12.25.3, “Expression Handling”](#)).

12.25.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in [Section 12.25.3, “Expression Handling”](#), and [Section 12.25.4, “Rounding Behavior”](#).

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+-----+
| (.1 + .2) = .3 |
+-----+
| 1              |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
```

```

+-----+
| (.1E0 + .2E0) = .3E0 |
+-----+
| 0 |
+-----+

```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;

```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```

+-----+
| d      | f      |
+-----+
| 1.0000 | 0.999999999999991 |
+-----+

```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers `x1` and `x2` that have scale `s1` and `s2`, the scale of the result is `s1 + s2`:

```

mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+

```

Example 3. Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. A value with a fractional part of .5 or greater is rounded away from zero to the nearest integer, as shown here:

```

mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+
| 3          | -3          |
+-----+

```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. A value with a fractional part exactly half way between two integers is rounded to the nearest even integer:

```

mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+
| 2            | -2            |
+-----+

```

Example 4. In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| 127   |
+-----+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i     |
+-----+
| NULL  |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
```

Empty set (0.01 sec)

Example 6. Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as **DECIMAL**:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
```

Query OK, 1 row affected (0.01 sec)

Records: 1 Duplicates: 0 Warnings: 0

```
mysql> DESCRIBE t;
```

Field	Type	Null	Key	Default	Extra
a	decimal(2,1) unsigned	NO		0.0	
b	double	NO		0	

2 rows in set (0.01 sec)

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
```

```
mysql> INSERT INTO t VALUES(1,1,1);
```

```
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
```

Field	Type	Null	Key	Default	Extra
AVG(i)	decimal(14,4)	YES		NULL	
AVG(d)	decimal(14,4)	YES		NULL	
AVG(f)	double	YES		NULL	

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

This chapter describes the syntax for the [SQL](#) statements supported by MySQL.

13.1 Data Definition Statements

13.1.1 Atomic Data Definition Statement Support

MySQL 8.0 supports atomic Data Definition Language (DDL) statements. This feature is referred to as *atomic DDL*. An atomic DDL statement combines the data dictionary updates, storage engine operations, and binary log writes associated with a DDL operation into a single, atomic operation. The operation is either committed, with applicable changes persisted to the data dictionary, storage engine, and binary log, or is rolled back, even if the server halts during the operation.

**Note**

Atomic DDL is not *transactional DDL*. DDL statements, atomic or otherwise, implicitly end any transaction that is active in the current session, as if you had done a [COMMIT](#) before executing the statement. This means that DDL statements cannot be performed within another transaction, within transaction control statements such as [START TRANSACTION ... COMMIT](#), or combined with other statements within the same transaction.

Atomic DDL is made possible by the introduction of the MySQL data dictionary in MySQL 8.0. In earlier MySQL versions, metadata was stored in metadata files, nontransactional tables, and storage engine-specific dictionaries, which necessitated intermediate commits. Centralized, transactional metadata storage provided by the MySQL data dictionary removed this barrier, making it possible to restructure DDL statement operations to be atomic.

The atomic DDL feature is described under the following topics in this section:

- [Supported DDL Statements](#)
- [Atomic DDL Characteristics](#)
- [Changes in DDL Statement Behavior](#)
- [Storage Engine Support](#)
- [Viewing DDL Logs](#)

Supported DDL Statements

The atomic DDL feature supports both table and non-table DDL statements. Table-related DDL operations require storage engine support, whereas non-table DDL operations do not. Currently, only the [InnoDB](#) storage engine supports atomic DDL.

- Supported table DDL statements include [CREATE](#), [ALTER](#), and [DROP](#) statements for databases, tablespaces, tables, and indexes, and the [TRUNCATE TABLE](#) statement.
- Supported non-table DDL statements include:
 - [CREATE](#) and [DROP](#) statements, and, if applicable, [ALTER](#) statements for stored programs, triggers, views, and user-defined functions (UDFs).
 - Account management statements: [CREATE](#), [ALTER](#), [DROP](#), and, if applicable, [RENAME](#) statements for users and roles, as well as [GRANT](#) and [REVOKE](#) statements.

The following statements are not supported by the atomic DDL feature:

- Table-related DDL statements that involve a storage engine other than [InnoDB](#).
- [INSTALL PLUGIN](#) and [UNINSTALL PLUGIN](#) statements.
- [INSTALL COMPONENT](#) and [UNINSTALL COMPONENT](#) statements.
- [CREATE SERVER](#), [ALTER SERVER](#), and [DROP SERVER](#) statements.

Atomic DDL Characteristics

The characteristics of atomic DDL statements include the following:

- Metadata updates, binary log writes, and storage engine operations, where applicable, are combined into a single atomic operation.
- There are no intermediate commits at the SQL layer during the DDL operation.
- Where applicable:

- The state of data dictionary, routine, event, and UDF caches is consistent with the status of the DDL operation, meaning that caches are updated to reflect whether or not the DDL operation was completed successfully or rolled back.
- The storage engine methods involved in a DDL operation do not perform intermediate commits, and the storage engine registers itself as part of the DDL operation.
- The storage engine supports redo and rollback of DDL operations, which is performed in the *Post-DDL* phase of the DDL operation.
- The visible behaviour of DDL operations is atomic, which changes the behavior of some DDL statements. See [Changes in DDL Statement Behavior](#).

Changes in DDL Statement Behavior

This section describes changes in DDL statement behavior due to the introduction of atomic DDL support.

- **DROP TABLE** operations are fully atomic if all named tables use an atomic DDL-supported storage engine. The statement either drops all tables successfully or is rolled back.

DROP TABLE fails with an error if a named table does not exist, and no changes are made, regardless of the storage engine. This change in behavior is demonstrated in the following example, where the **DROP TABLE** statement fails because a named table does not exist:

```
mysql> CREATE TABLE t1 (c1 INT);
mysql> DROP TABLE t1, t2;
ERROR 1051 (42S02): Unknown table 'test.t2'
mysql> SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| t1              |
+-----+
```

Prior to the introduction of atomic DDL, **DROP TABLE** reports an error for the named table that does not exist but succeeds for the named table that does exist:

```
mysql> CREATE TABLE t1 (c1 INT);
mysql> DROP TABLE t1, t2;
ERROR 1051 (42S02): Unknown table 'test.t2'
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

Note

Due to this change in behavior, a partially completed **DROP TABLE** statement on a MySQL 5.7 replication source server fails when replicated on a MySQL 8.0 replica. To avoid this failure scenario, use **IF EXISTS** syntax in **DROP TABLE** statements to prevent errors from occurring for tables that do not exist.

- **DROP DATABASE** is atomic if all tables use an atomic DDL-supported storage engine. The statement either drops all objects successfully or is rolled back. However, removal of the database directory from the file system occurs last and is not part of the atomic operation. If removal of the database directory fails due to a file system error or server halt, the **DROP DATABASE** transaction is not rolled back.
- For tables that do not use an atomic DDL-supported storage engine, table deletion occurs outside of the atomic **DROP TABLE** or **DROP DATABASE** transaction. Such table deletions are written to the binary log individually, which limits the discrepancy between the storage engine, data dictionary, and binary log to one table at most in the case of an interrupted **DROP TABLE** or **DROP DATABASE** operation. For operations that drop multiple tables, the tables that do not use an atomic DDL-supported storage engine are dropped before tables that do.

- `CREATE TABLE`, `ALTER TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`, `CREATE TABLESPACE`, and `DROP TABLESPACE` operations for tables that use an atomic DDL-supported storage engine are either fully committed or rolled back if the server halts during their operation. In earlier MySQL releases, interruption of these operations could cause discrepancies between the storage engine, data dictionary, and binary log, or leave behind orphan files. `RENAME TABLE` operations are only atomic if all named tables use an atomic DDL-supported storage engine.
- As of MySQL 8.0.21, on storage engines that support atomic DDL, the `CREATE TABLE ... SELECT` statement is logged as one transaction in the binary log when row-based replication is in use. Previously, it was logged as two transactions, one to create the table, and the other to insert data. A server failure between the two transactions or while inserting data could result in replication of an empty table. With the introduction of atomic DDL support, `CREATE TABLE ... SELECT` statements are now safe for row-based replication and permitted for use with GTID-based replication.

On storage engines that support both atomic DDL and foreign key constraints, creation of foreign keys is not permitted in `CREATE TABLE ... SELECT` statements when row-based replication is in use. Foreign key constraints can be added later using `ALTER TABLE`.

When `CREATE TABLE ... SELECT` is applied as an atomic operation, a metadata lock is held on the table while data is inserted, which prevents concurrent access to the table for the duration of the operation.

- `DROP VIEW` fails if a named view does not exist, and no changes are made. The change in behavior is demonstrated in this example, where the `DROP VIEW` statement fails because a named view does not exist:

```
mysql> CREATE VIEW test.viewA AS SELECT * FROM t;
mysql> DROP VIEW test.viewA, test.viewB;
ERROR 1051 (42S02): Unknown table 'test.viewB'
mysql> SHOW FULL TABLES IN test WHERE TABLE_TYPE LIKE 'VIEW';
+-----+-----+
| Tables_in_test | Table_type |
+-----+-----+
| viewA          | VIEW       |
+-----+-----+
```

Prior to the introduction of atomic DDL, `DROP VIEW` returns an error for the named view that does not exist but succeeds for the named view that does exist:

```
mysql> CREATE VIEW test.viewA AS SELECT * FROM t;
mysql> DROP VIEW test.viewA, test.viewB;
ERROR 1051 (42S02): Unknown table 'test.viewB'
mysql> SHOW FULL TABLES IN test WHERE TABLE_TYPE LIKE 'VIEW';
Empty set (0.00 sec)
```

Note

Due to this change in behavior, a partially completed `DROP VIEW` operation on a MySQL 5.7 replication source server fails when replicated on a MySQL 8.0 replica. To avoid this failure scenario, use `IF EXISTS` syntax in `DROP VIEW` statements to prevent an error from occurring for views that do not exist.

- Partial execution of account management statements is no longer permitted. Account management statements either succeed for all named users or roll back and have no effect if an error occurs. In earlier MySQL versions, account management statements that name multiple users could succeed for some users and fail for others.

The change in behavior is demonstrated in this example, where the second `CREATE USER` statement returns an error but fails because it cannot succeed for all named users.

```
mysql> CREATE USER userA;
```

```
mysql> CREATE USER userA, userB;
ERROR 1396 (HY000): Operation CREATE USER failed for 'userA'@'%'
mysql> SELECT User FROM mysql.user WHERE User LIKE 'user%';
+-----+
| User |
+-----+
| userA |
+-----+
```

Prior to the introduction of atomic DDL, the second `CREATE USER` statement returns an error for the named user that does not exist but succeeds for the named user that does exist:

```
mysql> CREATE USER userA;
mysql> CREATE USER userA, userB;
ERROR 1396 (HY000): Operation CREATE USER failed for 'userA'@'%'
mysql> SELECT User FROM mysql.user WHERE User LIKE 'user%';
+-----+
| User |
+-----+
| userA |
| userB |
+-----+
```

Note

Due to this change in behavior, partially completed account management statements on a MySQL 5.7 replication source server fail when replicated on a MySQL 8.0 replica. To avoid this failure scenario, use `IF EXISTS` or `IF NOT EXISTS` syntax, as appropriate, in account management statements to prevent errors related to named users.

Storage Engine Support

Currently, only the `InnoDB` storage engine supports atomic DDL. Storage engines that do not support atomic DDL are exempted from DDL atomicity. DDL operations involving exempted storage engines remain capable of introducing inconsistencies that can occur when operations are interrupted or only partially completed.

To support redo and rollback of DDL operations, `InnoDB` writes DDL logs to the `mysql.innodb_ddl_log` table, which is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace.

To view DDL logs that are written to the `mysql.innodb_ddl_log` table during a DDL operation, enable the `innodb_print_ddl_logs` configuration option. For more information, see [Viewing DDL Logs](#).

Note

The redo logs for changes to the `mysql.innodb_ddl_log` table are flushed to disk immediately regardless of the `innodb_flush_log_at_trx_commit` setting. Flushing the redo logs immediately avoids situations where data files are modified by DDL operations but the redo logs for changes to the `mysql.innodb_ddl_log` table resulting from those operations are not persisted to disk. Such a situation could cause errors during rollback or recovery.

The `InnoDB` storage engine executes DDL operations in phases. DDL operations such as `ALTER TABLE` may perform the *Prepare* and *Perform* phases multiple times prior to the *Commit* phase.

1. *Prepare*: Create the required objects and write the DDL logs to the `mysql.innodb_ddl_log` table. The DDL logs define how to roll forward and roll back the DDL operation.
2. *Perform*: Perform the DDL operation. For example, perform a create routine for a `CREATE TABLE` operation.

3. *Commit*: Update the data dictionary and commit the data dictionary transaction.
4. *Post-DDL*: Replay and remove DDL logs from the `mysql.innodb_ddl_log` table. To ensure that rollback can be performed safely without introducing inconsistencies, file operations such as renaming or removing data files are performed in this final phase. This phase also removes dynamic metadata from the `mysql.innodb_dynamic_metadata` data dictionary table for `DROP TABLE`, `TRUNCATE TABLE`, and other DDL operations that rebuild the table.

DDL logs are replayed and removed from the `mysql.innodb_ddl_log` table during the *Post-DDL* phase, regardless of whether the DDL operation is committed or rolled back. DDL logs should only remain in the `mysql.innodb_ddl_log` table if the server is halted during a DDL operation. In this case, the DDL logs are replayed and removed after recovery.

In a recovery situation, a DDL operation may be committed or rolled back when the server is restarted. If the data dictionary transaction that was performed during the *Commit* phase of a DDL operation is present in the redo log and binary log, the operation is considered successful and is rolled forward. Otherwise, the incomplete data dictionary transaction is rolled back when InnoDB replays data dictionary redo logs, and the DDL operation is rolled back.

Viewing DDL Logs

To view DDL logs that are written to the `mysql.innodb_ddl_log` data dictionary table during atomic DDL operations that involve the InnoDB storage engine, enable `innodb_print_ddl_logs` to have MySQL write the DDL logs to `stderr`. Depending on the host operating system and MySQL configuration, `stderr` may be the error log, terminal, or console window. See [Section 5.4.2.2, “Default Error Log Destination Configuration”](#).

InnoDB writes DDL logs to the `mysql.innodb_ddl_log` table to support redo and rollback of DDL operations. The `mysql.innodb_ddl_log` table is a hidden data dictionary table that resides in the `mysql.ibd` data dictionary tablespace. Like other hidden data dictionary tables, the `mysql.innodb_ddl_log` table cannot be accessed directly in non-debug versions of MySQL. (See [Section 14.1, “Data Dictionary Schema”](#).) The structure of the `mysql.innodb_ddl_log` table corresponds to this definition:

```
CREATE TABLE mysql.innodb_ddl_log (
  id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  thread_id BIGINT UNSIGNED NOT NULL,
  type INT UNSIGNED NOT NULL,
  space_id INT UNSIGNED,
  page_no INT UNSIGNED,
  index_id BIGINT UNSIGNED,
  table_id BIGINT UNSIGNED,
  old_file_path VARCHAR(512) COLLATE UTF8_BIN,
  new_file_path VARCHAR(512) COLLATE UTF8_BIN,
  KEY(thread_id)
);
```

- `id`: A unique identifier for a DDL log record.
- `thread_id`: Each DDL log record is assigned a `thread_id`, which is used to replay and remove DDL logs that belong to a particular DDL operation. DDL operations that involve multiple data file operations generate multiple DDL log records.
- `type`: The DDL operation type. Types include `FREE` (drop an index tree), `DELETE` (delete a file), `RENAME` (rename a file), or `DROP` (drop metadata from the `mysql.innodb_dynamic_metadata` data dictionary table).
- `space_id`: The tablespace ID.
- `page_no`: A page that contains allocation information; an index tree root page, for example.
- `index_id`: The index ID.
- `table_id`: The table ID.

- `old_file_path`: The old tablespace file path. Used by DDL operations that create or drop tablespace files; also used by DDL operations that rename a tablespace.
- `new_file_path`: The new tablespace file path. Used by DDL operations that rename tablespace files.

This example demonstrates enabling `innodb_print_ddl_logs` to view DDL logs written to `stderr` for a `CREATE TABLE` operation.

```
mysql> SET GLOBAL innodb_print_ddl_logs=1;
mysql> CREATE TABLE t1 (c1 INT) ENGINE = InnoDB;

[Note] [000000] InnoDB: DDL log insert : [DDL record: DELETE SPACE, id=18, thread_id=7,
space_id=5, old_file_path=./test/t1.ibd]
[Note] [000000] InnoDB: DDL log delete : by id 18
[Note] [000000] InnoDB: DDL log insert : [DDL record: REMOVE CACHE, id=19, thread_id=7,
table_id=1058, new_file_path=test/t1]
[Note] [000000] InnoDB: DDL log delete : by id 19
[Note] [000000] InnoDB: DDL log insert : [DDL record: FREE, id=20, thread_id=7,
space_id=5, index_id=132, page_no=4]
[Note] [000000] InnoDB: DDL log delete : by id 20
[Note] [000000] InnoDB: DDL log post ddl : begin for thread id : 7
[Note] [000000] InnoDB: DDL log post ddl : end for thread id : 7
```

13.1.2 ALTER DATABASE Statement

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_option ...

alter_option: {
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | [DEFAULT] ENCRYPTION [=] {'Y' | 'N'}
  | READ ONLY [=] {DEFAULT | 0 | 1}
}
```

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the data dictionary. This statement requires the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for `ALTER DATABASE`.

If the database name is omitted, the statement applies to the default database. In that case, an error occurs if there is no default database.

For any `alter_option` omitted from the statement, the database retains its current option value, with the exception that changing the character set may change the collation and vice versa.

- [Character Set and Collation Options](#)
- [Encryption Option](#)
- [Read Only Option](#)

Character Set and Collation Options

The `CHARACTER SET` option changes the default database character set. The `COLLATE` option changes the default database collation. For information about character set and collation names, see [Chapter 10, Character Sets, Collations, Unicode](#).

To see the available character sets and collations, use the `SHOW CHARACTER SET` and `SHOW COLLATION` statements, respectively. See [Section 13.7.7.3, “SHOW CHARACTER SET Statement”](#), and [Section 13.7.7.4, “SHOW COLLATION Statement”](#).

A stored routine that uses the database defaults when the routine is created includes those defaults as part of its definition. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).) If you change the default character set or

collation for a database, any stored routines that are to use the new defaults must be dropped and recreated.

Encryption Option

The `ENCRYPTION` option, introduced in MySQL 8.0.16, defines the default database encryption, which is inherited by tables created in the database. The permitted values are `'Y'` (encryption enabled) and `'N'` (encryption disabled). Only newly created tables inherit the default database encryption. For existing tables associated with the database, their encryption remains unchanged. If the `table_encryption_privilege_check` system variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required to specify a default encryption setting that differs from the value of the `default_table_encryption` system variable. For more information, see [Defining an Encryption Default for Schemas and General Tablespace](#)s.

Read Only Option

The `READ ONLY` option, introduced in MySQL 8.0.22, controls whether to permit modification of the database and objects within it. The permitted values are `DEFAULT` or `0` (not read only) and `1` (read only). This option is useful for database migration because a database for which `READ ONLY` is enabled can be migrated to another MySQL instance without concern that the database might be changed during the operation.

With NDB Cluster, making a database read only on one `mysqld` server is synchronized to other `mysqld` servers in the same cluster, so that the database becomes read only on all `mysqld` servers.

The `READ ONLY` option, if enabled, is displayed in the `INFORMATION_SCHEMA SCHEMATA_EXTENSIONS` table. See [Section 25.32, “The INFORMATION_SCHEMA SCHEMATA_EXTENSIONS Table”](#).

The `READ ONLY` option cannot be enabled for these system schemas: `mysql`, `information_schema`, `performance_schema`.

In `ALTER DATABASE` statements, the `READ ONLY` option interacts with other instances of itself and with other options as follows:

- An error occurs if multiple instances of `READ ONLY` conflict (for example, `READ ONLY = 1 READ ONLY = 0`).
- An `ALTER DATABASE` statement that contains only (nonconflicting) `READ ONLY` options is permitted even for a read-only database.
- A mix of (nonconflicting) `READ ONLY` options with other options is permitted if the read-only state of the database either before or after the statement permits modifications. If the read-only state both before and after prohibits changes, an error occurs.

This statement succeeds whether or not the database is read only:

```
ALTER DATABASE mydb READ ONLY = 0 DEFAULT COLLATE utf8mb4_bin;
```

This statement succeeds if the database is not read only, but fails if it is already read only:

```
ALTER DATABASE mydb READ ONLY = 1 DEFAULT COLLATE utf8mb4_bin;
```

Enabling `READ ONLY` affects all users of the database, with these exceptions that are not subject to read-only checks:

- Statements executed by the server as part of server initialization, restart, upgrade, or replication.
- Statements in a file named at server startup by the `init_file` system variable.
- `TEMPORARY` tables; it is possible to create, alter, drop, and write to `TEMPORARY` tables in a read-only database.

- NDB Cluster non-SQL inserts and updates.

Other than for the excepted operations just listed, enabling `READ ONLY` prohibits write operations to the database and its objects, including their definitions, data, and metadata. The following list details affected SQL statements and operations:

- The database itself:
 - `CREATE DATABASE`
 - `ALTER DATABASE` (except to change the `READ ONLY` option)
 - `DROP DATABASE`
- Views:
 - `CREATE VIEW`
 - `ALTER VIEW`
 - `DROP VIEW`
 - Selecting from views that invoke functions with side effects.
 - Updating updatable views.
 - Statements that create or drop objects in a writable database are rejected if they affect metadata of a view in a read-only database (for example, by making the view valid or invalid).
- Stored routines:
 - `CREATE PROCEDURE`
 - `DROP PROCEDURE`
 - `CALL` (of procedures with side effects)
 - `CREATE FUNCTION`
 - `DROP FUNCTION`
 - `SELECT` (of functions with side effects)
 - For procedures and functions, read-only checks follow prelocking behavior. For `CALL` statements, read-only checks are done on a per-statement basis, so if some conditionally executed statement writing to a read-only database does not actually execute, the call still succeeds. On the other hand, for a function called within a `SELECT`, execution of the function body happens in prelocked mode. As long as a some statement within the function writes to a read-only database, execution of the function fails with an error regardless of whether the statement actually executes.
- Triggers:
 - `CREATE TRIGGER`
 - `DROP TRIGGER`
 - Trigger invocation.
- Events:
 - `CREATE EVENT`
 - `ALTER EVENT`

- `DROP EVENT`
- Event execution:
 - Executing an event in the database fails because that would change the last-execution timestamp, which is event metadata stored in the data dictionary. Failure of event execution also has the effect of causing the event scheduler to stop.
 - If an event writes to an object in a read-only database, execution of the event fails with an error, but the event scheduler is not stopped.
- Tables:
 - `CREATE TABLE`
 - `ALTER TABLE`
 - `CREATE INDEX`
 - `DROP INDEX`
 - `RENAME TABLE`
 - `TRUNCATE TABLE`
 - `DROP TABLE`
 - `DELETE`
 - `INSERT`
 - `IMPORT TABLE`
 - `LOAD DATA`
 - `LOAD XML`
 - `REPLACE`
 - `UPDATE`
- For cascading foreign keys where the child table is in a read-only database, updates and deletes on the parent are rejected even if the child table is not directly affected.
- For a `MERGE` table such as `CREATE TABLE s1.t(i int) ENGINE MERGE UNION (s2.t, s3.t), INSERT_METHOD=...`, the following behavior applies:
 - Inserting into the `MERGE` table (`INSERT into s1.t`) fails if at least one of `s1`, `s2`, `s3` is read only, regardless of insert method. The insert is refused even if it would actually end up in a writable table.
 - Dropping the `MERGE` table (`DROP TABLE s1.t`) succeeds as long as `s1` is not read only. It is permitted to drop a `MERGE` table that refers to a read-only database.

An `ALTER DATABASE` statement blocks until all concurrent transactions that have already accessed an object in the database being altered have committed. Conversely, a write transaction accessing an object in a database being altered in a concurrent `ALTER DATABASE` blocks until the `ALTER DATABASE` has committed.

If the Clone plugin is used to clone a local or remote data directory, the databases in the clone retain the read-only state they had in the source data directory. The read-only state does not affect the

cloning process itself. If it is not desirable to have the same database read-only state in the clone, the option must be changed explicitly for the clone after the cloning process has finished, using [ALTER DATABASE](#) operations on the clone.

When cloning from a donor to a recipient, if the recipient has a user database that is read only, cloning fails with an error message. Cloning may be retried after making the database writable.

[READ ONLY](#) is permitted for [ALTER DATABASE](#), but not for [CREATE DATABASE](#). However, for a read-only database, the statement produced by [SHOW CREATE DATABASE](#) does include [READ ONLY=1](#) within a comment to indicate its read-only status:

```
mysql> ALTER DATABASE mydb READ ONLY = 1;
mysql> SHOW CREATE DATABASE mydb\G
***** 1. row *****
      Database: mydb
Create Database: CREATE DATABASE `mydb`
                /*!40100 DEFAULT CHARACTER SET utf8mb4
                  COLLATE utf8mb4_0900_ai_ci */
                /*!80016 DEFAULT ENCRYPTION='N' */
                /* READ ONLY = 1 */
```

If the server executes a [CREATE DATABASE](#) statement containing such a comment, the server ignores the comment and the [READ ONLY](#) option is not processed. This has implications for [mysqldump](#) and [mysqlpump](#), which use [SHOW CREATE DATABASE](#) to produce [CREATE DATABASE](#) statements in dump output:

- In a dump file, the [CREATE DATABASE](#) statement for a read-only database contains the commented [READ ONLY](#) option.
- The dump file can be restored as usual, but because the server ignores the commented [READ ONLY](#) option, the restored database is *not* read only. If the database is to be read only after being restored, you must execute [ALTER DATABASE](#) manually to make it so.

Suppose that [mydb](#) is read only and you dump it as follows:

```
shell> mysqldump --databases mydb > mydb.sql
```

A restore operation later must be followed by [ALTER DATABASE](#) if [mydb](#) should still be read only:

```
shell> mysql
mysql> SOURCE mydb.sql;
mysql> ALTER DATABASE mydb READ ONLY = 1;
```

MySQL Enterprise Backup is not subject to this issue. It backs up and restores a read-only database like any other, but enables the [READ ONLY](#) option at restore time if it was enabled at backup time.

[ALTER DATABASE](#) is written to the binary log, so a change to the [READ ONLY](#) option on a replication source server also affects replicas. To prevent this from happening, binary logging must be disabled prior to execution of the [ALTER DATABASE](#) statement. For example, to prepare for migrating a database without affecting replicas, perform these operations:

1. Within a single session, disable binary logging and enable [READ ONLY](#) for the database:

```
mysql> SET sql_log_bin = OFF;
mysql> ALTER DATABASE mydb READ ONLY = 1;
```

2. Dump the database, for example, with [mysqldump](#) or [mysqlpump](#):

```
shell> mysqldump --databases mydb > mydb.sql
```

3. Within a single session, disable binary logging and disable [READ ONLY](#) for the database:

```
mysql> SET sql_log_bin = OFF;
mysql> ALTER DATABASE mydb READ ONLY = 0;
```

13.1.3 ALTER EVENT Statement

```
ALTER
  [DEFINER = user]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'string']
  [DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 13.1.13, “CREATE EVENT Statement”](#).)

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
>     ON SCHEDULE
>     EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
  ON SCHEDULE
    EVERY 6 HOUR
  COMMENT 'A sample comment.'
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
  ON SCHEDULE
    EVERY 12 HOUR
  STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
  ON SCHEDULE
    AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO
    TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
  DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines

or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
  RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
  RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

Note

There is no `RENAME EVENT` statement.

The value `DISABLE ON SLAVE` is used on a replica instead of `ENABLE` or `DISABLE` to indicate an event that was created on the replication source server and replicated to the replica, but that is not executed on the replica. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 17.5.1.16, “Replication of Invoked Features”](#), for more information.

13.1.4 ALTER FUNCTION Statement

```
ALTER FUNCTION func_name [characteristic ...]

characteristic: {
  COMMENT 'string'
| LANGUAGE SQL
| { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
| SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using `DROP FUNCTION` and `CREATE FUNCTION`.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in [Section 24.7, “Stored Program Binary Logging”](#).

13.1.5 ALTER INSTANCE Statement

```
ALTER INSTANCE instance_action

instance_action: {
  {ENABLE|DISABLE} INNODB REDO_LOG
| ROTATE INNODB MASTER KEY
| ROTATE BINLOG MASTER KEY
}
```

```
| RELOAD TLS
  [FOR CHANNEL {mysql_main | mysql_admin}]
  [NO ROLLBACK ON ERROR]
}
```

ALTER INSTANCE defines actions applicable to a MySQL server instance. The statement supports these actions:

- **ALTER INSTANCE {ENABLE | DISABLE} INNODB REDO_LOG**

This action enables or disables **InnoDB** redo logging. Redo logging is enabled by default. This feature is intended only for loading data into a new MySQL instance. The statement is not written to the binary log. Introduced in MySQL 8.0.21.

Warning

Do not disable redo logging on a production system. While it is permitted to shutdown and restart the server while redo logging is disabled, an unexpected server stoppage while redo logging is disabled can cause data loss and instance corruption.

An **ALTER INSTANCE [ENABLE|DISABLE] INNODB REDO_LOG** operation requires an exclusive backup lock, which prevents other **ALTER INSTANCE** operations from executing concurrently. Other **ALTER INSTANCE** operations must wait for the lock to be released before executing.

For more information, see [Disabling Redo Logging](#).

- **ALTER INSTANCE ROTATE INNODB MASTER KEY**

This action rotates the master encryption key used for **InnoDB** tablespace encryption. Key rotation requires the **ENCRYPTION_KEY_ADMIN** or **SUPER** privilege. To perform this action, a keyring plugin must be installed and configured. For instructions, see [Section 6.4.4, “The MySQL Keyring”](#).

ALTER INSTANCE ROTATE INNODB MASTER KEY supports concurrent DML. However, it cannot be run concurrently with **CREATE TABLE ... ENCRYPTION** or **ALTER TABLE ... ENCRYPTION** operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

ALTER INSTANCE ROTATE INNODB MASTER KEY statements are written to the binary log so that they can be executed on replicated servers.

For additional **ALTER INSTANCE ROTATE INNODB MASTER KEY** usage information, see [Section 15.13, “InnoDB Data-at-Rest Encryption”](#).

- **ALTER INSTANCE ROTATE BINLOG MASTER KEY**

This action rotates the binary log master key used for binary log encryption. Key rotation for the binary log master key requires the **BINLOG_ENCRYPTION_ADMIN** or **SUPER** privilege. The statement cannot be used if the **binlog_encryption** system variable is set to **OFF**. To perform this action, a keyring plugin must be installed and configured. For instructions, see [Section 6.4.4, “The MySQL Keyring”](#).

ALTER INSTANCE ROTATE BINLOG MASTER KEY actions are not written to the binary log and are not executed on replicas. Binary log master key rotation can therefore be carried out in replication environments including a mix of MySQL versions. To schedule regular rotation of the binary log master key on all applicable source and replica servers, you can enable the MySQL Event Scheduler on each server and issue the **ALTER INSTANCE ROTATE BINLOG MASTER KEY** statement using a **CREATE EVENT** statement. If you rotate the binary log master key because you suspect that the current or any of the previous binary log master keys might have been compromised, issue the statement on every applicable source and replica server, which enables you to verify immediate compliance.

For additional `ALTER INSTANCE ROTATE BINLOG MASTER KEY` usage information, including what to do if the process does not complete correctly or is interrupted by an unexpected server halt, see [Section 17.3.2, “Encrypting Binary Log Files and Relay Log Files”](#).

- `ALTER INSTANCE RELOAD TLS`

This action reconfigures a TLS context from the current values of the system variables that define the context. It also updates the status variables that reflect the active context values. This action requires the `CONNECTION_ADMIN` privilege. For additional information about reconfiguring the TLS context, including which system and status variables are context-related, see [Server-Side Runtime Configuration and Monitoring for Encrypted Connections](#).

By default, the statement reloads the TLS context for the main connection interface. If the `FOR CHANNEL` clause (available as of MySQL 8.0.21) is given, the statement reloads the TLS context for the named channel: `mysql_main` for the main connection interface, `mysql_admin` for the administrative connection interface. For information about the different interfaces, see [Section 5.1.12.1, “Connection Interfaces”](#). The updated TLS context properties are exposed in the Performance Schema `tls_channel_status` table. See [Section 26.12.19.8, “The `tls_channel_status` Table”](#).

Updating the TLS context for the main interface may also affect the administrative interface because unless some nondefault TLS value is configured for that interface, it uses the same TLS context as the main interface.

By default, the `RELOAD TLS` action rolls back with an error and has no effect if the configuration values do not permit creation of the new TLS context. The previous context values continue to be used for new connections. If the optional `NO ROLLBACK ON ERROR` clause is given and the new context cannot be created, rollback does not occur. Instead, a warning is generated and encryption is disabled for new connections on the interface to which the statement applies.

`ALTER INSTANCE RELOAD TLS` statements are not written to the binary log (and thus are not replicated). TLS configuration is local and depends on local files not necessarily present on all servers involved.

13.1.6 ALTER LOGFILE GROUP Statement

```
ALTER LOGFILE GROUP logfile_group
  ADD UNDOFILE 'file_name'
  [INITIAL_SIZE [=] size]
  [WAIT]
  ENGINE [=] engine_name
```

This statement adds an `UNDO` file named '*file_name*' to an existing log file group *logfile_group*. An `ALTER LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. No `DROP UNDOFILE` clause is currently supported.

Note

All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and an undo log file with the same name, or an undo log file and a data file with the same name.

The optional `INITIAL_SIZE` parameter sets the `UNDO` file's initial size in bytes; if not specified, the initial size defaults to 134217728 (128 MB). You may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters `M` (megabytes) or `G` (gigabytes). (Bug #13116514, Bug #16104705, Bug #62858)

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB). (Bug #29574)

Note

`WAIT` is parsed but otherwise ignored. This keyword currently has no effect, and is intended for future expansion.

The `ENGINE` parameter (required) determines the storage engine which is used by this log file group, with `engine_name` being the name of the storage engine. Currently, the only accepted values for `engine_name` are “`NDBCLUSTER`” and “`NDB`”. The two values are equivalent.

Here is an example, which assumes that the log file group `lg_3` has already been created using `CREATE LOGFILE GROUP` (see [Section 13.1.16, “CREATE LOGFILE GROUP Statement”](#)):

```
ALTER LOGFILE GROUP lg_3
  ADD UNDOFILE 'undo_10.dat'
  INITIAL_SIZE=32M
  ENGINE=NDBCLUSTER;
```

When `ALTER LOGFILE GROUP` is used with `ENGINE = NDBCLUSTER` (alternatively, `ENGINE = NDB`), an `UNDO` log file is created on each NDB Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT FILE_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg_3';
```

FILE_NAME	LOGFILE_GROUP_NUMBER	EXTRA
newdata.dat	0	CLUSTER_NODE=3
newdata.dat	0	CLUSTER_NODE=4
undo_10.dat	11	CLUSTER_NODE=3
undo_10.dat	11	CLUSTER_NODE=4

```
4 rows in set (0.01 sec)
```

(See [Section 25.15, “The INFORMATION_SCHEMA FILES Table”](#).)

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

`ALTER LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. For more information, see [Section 22.5.10, “NDB Cluster Disk Data Tables”](#).

13.1.7 ALTER PROCEDURE Statement

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic: {
  COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
}
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using `DROP PROCEDURE` and `CREATE PROCEDURE`.

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the

`automatic_sp_privileges` system variable. See [Section 24.2.2, “Stored Routines and MySQL Privileges”](#).

13.1.8 ALTER SERVER Statement

```
ALTER SERVER server_name
  OPTIONS (option [, option] ...)
```

Alters the server information for *server_name*, adjusting any of the options permitted in the `CREATE SERVER` statement. The corresponding fields in the `mysql.servers` table are updated accordingly. This statement requires the `SUPER` privilege.

For example, to update the `USER` option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

13.1.9 ALTER TABLE Statement

```
ALTER TABLE tbl_name
  [alter_option [, alter_option] ...]
  [partition_options]

alter_option: {
  table_options
| ADD [COLUMN] col_name column_definition
  [FIRST | AFTER col_name]
| ADD [COLUMN] (col_name column_definition,...)
| ADD {INDEX | KEY} [index_name]
  [index_type] (key_part,...) [index_option] ...
| ADD {FULLTEXT | SPATIAL} [INDEX | KEY] [index_name]
  (key_part,...) [index_option] ...
| ADD [CONSTRAINT [symbol]] PRIMARY KEY
  [index_type] (key_part,...)
  [index_option] ...
| ADD [CONSTRAINT [symbol]] UNIQUE [INDEX | KEY]
  [index_name] [index_type] (key_part,...)
  [index_option] ...
| ADD [CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (col_name,...)
  reference_definition
| ADD [CONSTRAINT [symbol]] CHECK (expr) [[NOT] ENFORCED]
| DROP {CHECK | CONSTRAINT} symbol
| ALTER {CHECK | CONSTRAINT} symbol [NOT] ENFORCED
| ALGORITHM [=] {DEFAULT | INSTANT | INPLACE | COPY}
| ALTER [COLUMN] col_name
  {SET DEFAULT {literal | (expr)} | DROP DEFAULT}
| ALTER INDEX index_name {VISIBLE | INVISIBLE}
| CHANGE [COLUMN] old_col_name new_col_name column_definition
  [FIRST | AFTER col_name]
| [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
| {DISABLE | ENABLE} KEYS
| {DISCARD | IMPORT} TABLESPACE
| DROP [COLUMN] col_name
| DROP {INDEX | KEY} index_name
| DROP PRIMARY KEY
| DROP FOREIGN KEY fk_symbol
| FORCE
| LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
| MODIFY [COLUMN] col_name column_definition
  [FIRST | AFTER col_name]
| ORDER BY col_name [, col_name] ...
| RENAME COLUMN old_col_name TO new_col_name
| RENAME {INDEX | KEY} old_index_name TO new_index_name
| RENAME [TO | AS] new_tbl_name
```

```

| {WITHOUT | WITH} VALIDATION
}

partition_options:
    partition_option [partition_option] ...

partition_option: {
    ADD PARTITION (partition_definition)
| DROP PARTITION partition_names
| DISCARD PARTITION {partition_names | ALL} TABLESPACE
| IMPORT PARTITION {partition_names | ALL} TABLESPACE
| TRUNCATE PARTITION {partition_names | ALL}
| COALESCE PARTITION number
| REORGANIZE PARTITION partition_names INTO (partition_definitions)
| EXCHANGE PARTITION partition_name WITH TABLE tbl_name [{WITH | WITHOUT} VALIDATION]
| ANALYZE PARTITION {partition_names | ALL}
| CHECK PARTITION {partition_names | ALL}
| OPTIMIZE PARTITION {partition_names | ALL}
| REBUILD PARTITION {partition_names | ALL}
| REPAIR PARTITION {partition_names | ALL}
| REMOVE PARTITIONING
}

key_part: {col_name [(length)] | (expr)} [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option: {
    KEY_BLOCK_SIZE [=] value
| index_type
| WITH PARSER parser_name
| COMMENT 'string'
| {VISIBLE | INVISIBLE}
}

table_options:
    table_option [[,] table_option] ...

table_option: {
    AUTO_INCREMENT [=] value
| AVG_ROW_LENGTH [=] value
| [DEFAULT] CHARACTER SET [=] charset_name
| CHECKSUM [=] {0 | 1}
| [DEFAULT] COLLATE [=] collation_name
| COMMENT [=] 'string'
| COMPRESSION [=] {'ZLIB' | 'LZ4' | 'NONE'}
| CONNECTION [=] 'connect_string'
| {DATA | INDEX} DIRECTORY [=] 'absolute path to directory'
| DELAY_KEY_WRITE [=] {0 | 1}
| ENCRYPTION [=] {'Y' | 'N'}
| ENGINE [=] engine_name
| ENGINE_ATTRIBUTE [=] 'string'
| INSERT_METHOD [=] { NO | FIRST | LAST }
| KEY_BLOCK_SIZE [=] value
| MAX_ROWS [=] value
| MIN_ROWS [=] value
| PACK_KEYS [=] {0 | 1 | DEFAULT}
| PASSWORD [=] 'string'
| ROW_FORMAT [=] {DEFAULT | DYNAMIC | FIXED | COMPRESSED | REDUNDANT | COMPACT}
| SECONDARY_ENGINE_ATTRIBUTE [=] 'string'
| STATS_AUTO_RECALC [=] {DEFAULT | 0 | 1}
| STATS_PERSISTENT [=] {DEFAULT | 0 | 1}
| STATS_SAMPLE_PAGES [=] value
| TABLESPACE tablespace_name [STORAGE {DISK | MEMORY}]
| UNION [=] (tbl_name[,tbl_name]...)
}

partition_options:
    (see CREATE TABLE options)

```

[ALTER TABLE](#) changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use [ALTER TABLE](#), you need [ALTER](#), [CREATE](#), and [INSERT](#) privileges for the table. Renaming a table requires [ALTER](#) and [DROP](#) on the old table, [ALTER](#), [CREATE](#), and [INSERT](#) on the new table.
- Following the table name, specify the alterations to be made. If none are given, [ALTER TABLE](#) does nothing.
- The syntax for many of the permissible alterations is similar to clauses of the [CREATE TABLE](#) statement. *column_definition* clauses use the same syntax for [ADD](#) and [CHANGE](#) as for [CREATE TABLE](#). For more information, see [Section 13.1.20, “CREATE TABLE Statement”](#).
- The word [COLUMN](#) is optional and can be omitted, except for [RENAME COLUMN](#) (to distinguish a column-renaming operation from the [RENAME](#) table-renaming operation).
- Multiple [ADD](#), [ALTER](#), [DROP](#), and [CHANGE](#) clauses are permitted in a single [ALTER TABLE](#) statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per [ALTER TABLE](#) statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- If a storage engine does not support an attempted [ALTER TABLE](#) operation, a warning may result. Such warnings can be displayed with [SHOW WARNINGS](#). See [Section 13.7.7.42, “SHOW WARNINGS Statement”](#). For information on troubleshooting [ALTER TABLE](#), see [Section B.3.6.1, “Problems with ALTER TABLE”](#).
- For information about generated columns, see [Section 13.1.9.2, “ALTER TABLE and Generated Columns”](#).
- For usage examples, see [Section 13.1.9.3, “ALTER TABLE Examples”](#).
- InnoDB in MySQL 8.0.17 and later supports addition of multi-valued indexes on JSON columns using a *key_part* specification can take the form [\(CAST json_path AS type ARRAY\)](#). See [Multi-Valued Indexes](#), for detailed information regarding multi-valued index creation and usage of, as well as restrictions and limitations on multi-valued indexes.
- With the [mysql_info\(\)](#) C API function, you can find out how many rows were copied by [ALTER TABLE](#). See [mysql_info\(\)](#).

There are several additional aspects to the [ALTER TABLE](#) statement, described under the following topics in this section:

- [Table Options](#)
- [Performance and Space Requirements](#)
- [Concurrency Control](#)
- [Adding and Dropping Columns](#)
- [Renaming, Redefining, and Reordering Columns](#)
- [Primary Keys and Indexes](#)
- [Foreign Keys and Other Constraints](#)
- [Changing the Character Set](#)
- [Importing InnoDB Tables](#)
- [Row Order for MyISAM Tables](#)

- [Partitioning Options](#)

Table Options

table_options signifies table options of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, `AVG_ROW_LENGTH`, `MAX_ROWS`, `ROW_FORMAT`, or `TABLESPACE`.

For descriptions of all table options, see [Section 13.1.20, “CREATE TABLE Statement”](#). However, `ALTER TABLE` ignores `DATA DIRECTORY` and `INDEX DIRECTORY` when given as table options. `ALTER TABLE` permits them only as partitioning options, and requires that you have the `FILE` privilege.

Use of table options with `ALTER TABLE` provides a convenient way of altering single table characteristics. For example:

- If `t1` is currently not an `InnoDB` table, this statement changes its storage engine to `InnoDB`:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

- See [Section 15.6.1.5, “Converting Tables from MyISAM to InnoDB”](#) for considerations when switching tables to the `InnoDB` storage engine.
- When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.
- Running `ALTER TABLE tbl_name ENGINE=INNODB` on an existing `InnoDB` table performs a “null” `ALTER TABLE` operation, which can be used to defragment an `InnoDB` table, as described in [Section 15.11.4, “Defragmenting a Table”](#). Running `ALTER TABLE tbl_name FORCE` on an `InnoDB` table performs the same function.
- `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL](#). For more information, see [Section 15.12, “InnoDB and Online DDL”](#).
- The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.11, “Server SQL Modes”](#).
- To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.
- To change the `InnoDB` table to use compressed row-storage format:

```
ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
```

- The `ENCRYPTION` clause enables or disables page-level data encryption for an `InnoDB` table. A keyring plugin must be installed and configured to enable encryption.

If the `table_encryption_privilege_check` variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required to use an `ENCRYPTION` clause with a setting that differs from the default schema encryption setting.

Prior to MySQL 8.0.16, the `ENCRYPTION` clause was only supported when altering tables residing in file-per-table tablespaces. As of MySQL 8.0.16, the `ENCRYPTION` clause is also supported for tables residing in general tablespaces.

For tables that reside in general tablespaces, table and tablespace encryption must match.

Altering table encryption by moving a table to a different tablespace or changing the storage engine is not permitted without explicitly specifying an `ENCRYPTION` clause.

As of MySQL 8.0.16, specifying an `ENCRYPTION` clause with a value other than `'N'` or `''` is not permitted if the table uses a storage engine that does not support encryption. Previously, the clause

was accepted. Attempting to create a table without an [ENCRYPTION](#) clause in an encryption-enabled schema using a storage engine that does not support encryption is also not permitted.

For more information, see [Section 15.13, “InnoDB Data-at-Rest Encryption”](#).

- To reset the current auto-increment value:

```
ALTER TABLE t1 AUTO_INCREMENT = 13;
```

You cannot reset the counter to a value less than or equal to the value that is currently in use. For both [InnoDB](#) and [MyISAM](#), if the value is less than or equal to the maximum value currently in the [AUTO_INCREMENT](#) column, the value is reset to the current maximum [AUTO_INCREMENT](#) column value plus one.

- To change the default table character set:

```
ALTER TABLE t1 CHARACTER SET = utf8;
```

See also [Changing the Character Set](#).

- To add (or change) a table comment:

```
ALTER TABLE t1 COMMENT = 'New table comment';
```

- Use [ALTER TABLE](#) with the [TABLESPACE](#) option to move [InnoDB](#) tables between existing [general tablespaces](#), [file-per-table tablespaces](#), and the [system tablespace](#). See [Moving Tables Between Tablespaces Using ALTER TABLE](#).
- [ALTER TABLE ... TABLESPACE](#) operations always cause a full table rebuild, even if the [TABLESPACE](#) attribute has not changed from its previous value.
- [ALTER TABLE ... TABLESPACE](#) syntax does not support moving a table from a temporary tablespace to a persistent tablespace.
- The [DATA DIRECTORY](#) clause, which is supported with [CREATE TABLE ... TABLESPACE](#), is not supported with [ALTER TABLE ... TABLESPACE](#), and is ignored if specified.
- For more information about the capabilities and limitations of the [TABLESPACE](#) option, see [CREATE TABLE](#).
- MySQL NDB Cluster 8.0 supports setting [NDB_TABLE](#) options for controlling a table's partition balance (fragment count type), read-from-any-replica capability, full replication, or any combination of these, as part of the table comment for an [ALTER TABLE](#) statement in the same manner as for [CREATE TABLE](#), as shown in this example:

```
ALTER TABLE t1 COMMENT = "NDB_TABLE=READ_BACKUP=0,PARTITION_BALANCE=FOR_RA_BY_NODE";
```

Bear in mind that [ALTER TABLE ... COMMENT ...](#) discards any existing comment for the table. See [Setting NDB_TABLE options](#), for additional information and examples.

- [ENGINE_ATTRIBUTE](#) and [SECONDARY_ENGINE_ATTRIBUTE](#) options (available as of MySQL 8.0.21) are used to specify table, column, and index attributes for primary and secondary storage engines. The options are reserved for future use. Index attributes cannot be altered. An index must be dropped and added back with the desired change, which can be performed in a single [ALTER TABLE](#) statement.

To verify that the table options were changed as intended, use [SHOW CREATE TABLE](#), or query the [INFORMATION_SCHEMA.TABLES](#) table.

Performance and Space Requirements

[ALTER TABLE](#) operations are processed using one of the following algorithms:

- **COPY**: Operations are performed on a copy of the original table, and table data is copied from the original table to the new table row by row. Concurrent DML is not permitted.
- **INPLACE**: Operations avoid copying table data but may rebuild the table in place. An exclusive metadata lock on the table may be taken briefly during preparation and execution phases of the operation. Typically, concurrent DML is supported.
- **INSTANT**: Operations only modify metadata in the data dictionary. No exclusive metadata locks are taken on the table during preparation and execution, and table data is unaffected, making operations instantaneous. Concurrent DML is permitted. (Introduced in MySQL 8.0.12)

The **ALGORITHM** clause is optional. If the **ALGORITHM** clause is omitted, MySQL uses **ALGORITHM=INSTANT** for storage engines and **ALTER TABLE** clauses that support it. Otherwise, **ALGORITHM=INPLACE** is used. If **ALGORITHM=INPLACE** is not supported, **ALGORITHM=COPY** is used.

Specifying an **ALGORITHM** clause requires the operation to use the specified algorithm for clauses and storage engines that support it, or fail with an error otherwise. Specifying **ALGORITHM=DEFAULT** is the same as omitting the **ALGORITHM** clause.

ALTER TABLE operations that use the **COPY** algorithm wait for other operations that are modifying the table to complete. After alterations are applied to the table copy, data is copied over, the original table is deleted, and the table copy is renamed to the name of the original table. While the **ALTER TABLE** operation executes, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table started after the **ALTER TABLE** operation begins are stalled until the new table is ready, then are automatically redirected to the new table. The temporary copy of the table is created in the database directory of the original table unless it is a **RENAME TO** operation that moves the table to a database that resides in a different directory.

The exception referred to earlier is that **ALTER TABLE** blocks reads (not just writes) at the point where it is ready to clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads and writes.

An **ALTER TABLE** operation that uses the **COPY** algorithm prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of **LOCK=SHARED** (allow queries but not DML). You can further restrict concurrency for operations that support the **LOCK** clause by specifying **LOCK=EXCLUSIVE**, which prevents DML and queries. For more information, see [Concurrency Control](#).

To force use of the **COPY** algorithm for an **ALTER TABLE** operation that would otherwise not use it, specify **ALGORITHM=COPY** or enable the `old_alter_table` system variable. If there is a conflict between the `old_alter_table` setting and an **ALGORITHM** clause with a value other than **DEFAULT**, the **ALGORITHM** clause takes precedence.

For **InnoDB** tables, an **ALTER TABLE** operation that uses the **COPY** algorithm on a table that resides in a **shared tablespace** can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table residing in a shared tablespace, the additional space used during the operation is not released back to the operating system as it is for a table that resides in a **file-per-table** tablespace.

For information about space requirements for online DDL operations, see [Section 15.12.3, “Online DDL Space Requirements”](#).

ALTER TABLE operations that support the **INPLACE** algorithm include:

- **ALTER TABLE** operations supported by the **InnoDB online DDL** feature. See [Section 15.12.1, “Online DDL Operations”](#).
- Renaming a table. MySQL renames files that correspond to the table `tbl_name` without making a copy. (You can also use the **RENAME TABLE** statement to rename tables. See [Section 13.1.36, “RENAME TABLE Statement”](#).) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.

- Operations that only modify table metadata. These operations are immediate because the server does not touch table contents. Metadata-only operations include:
 - Renaming a column. In NDB Cluster 8.0.18 and later, this operation can also be performed online.
 - Changing the default value of a column (except for [NDB](#) tables).
 - Modifying the definition of an [ENUM](#) or [SET](#) column by adding new enumeration or set members to the *end* of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a [SET](#) column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this requires a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.
 - Changing the definition of a spatial column to remove the [SRID](#) attribute. (Adding or changing an [SRID](#) attribute does require a rebuild and cannot be done in place because the server must verify that all values have the specified SRID value.)
- As of MySQL 8.0.14, changing a column character set, when these conditions apply:
 - The column data type is [CHAR](#), [VARCHAR](#), a [TEXT](#) type, or [ENUM](#).
 - The character set change is from [utf8mb3](#) to [utf8mb4](#), or any character set to [binary](#).
 - There is no index on the column.
- As of MySQL 8.0.14, changing a generated column, when these conditions apply:
 - For [InnoDB](#) tables, statements that modify generated stored columns but do not change their type, expression, or nullability.
 - For non-[InnoDB](#) tables, statements that modify generated stored or virtual columns but do not change their type, expression, or nullability.

An example of such a change is a change to the column comment.

- Renaming an index.
- Adding or dropping a secondary index, for [InnoDB](#) and [NDB](#) tables. See [Section 15.12.1, “Online DDL Operations”](#).
- For [NDB](#) tables, operations that add and drop indexes on variable-width columns. These operations occur online, without table copying and without blocking concurrent DML actions for most of their duration. See [Section 22.5.11, “Online Operations with ALTER TABLE in NDB Cluster”](#).
- Modifying index visibility with an [ALTER INDEX](#) operation.
- Column modifications of tables containing generated columns that depend on columns with a [DEFAULT](#) value if the modified columns are not involved in the generated column expressions. For example, changing the [NULL](#) property of a separate column can be done in place without a table rebuild.

[ALTER TABLE](#) operations that support the [INSTANT](#) algorithm include:

- Adding a column. This feature is referred to as “Instant [ADD COLUMN](#)”. Limitations apply. See [Section 15.12.1, “Online DDL Operations”](#).
- Adding or dropping a virtual column.
- Adding or dropping a column default value.
- Modifying the definition of an [ENUM](#) or [SET](#) column. The same restrictions apply as described above for [ALGORITHM=INSTANT](#).

- Changing the index type.
- Renaming a table. The same restrictions apply as described above for `ALGORITHM=INSTANT`.

For more information about operations that support `ALGORITHM=INSTANT`, see [Section 15.12.1, “Online DDL Operations”](#).

`ALTER TABLE` upgrades MySQL 5.5 temporal columns to 5.6 format for `ADD COLUMN`, `CHANGE COLUMN`, `MODIFY COLUMN`, `ADD INDEX`, and `FORCE` operations. This conversion cannot be done using the `INPLACE` algorithm because the table must be rebuilt, so specifying `ALGORITHM=INPLACE` in these cases results in an error. Specify `ALGORITHM=COPY` if necessary.

If an `ALTER TABLE` operation on a multicolumn index used to partition a table by `KEY` changes the order of the columns, it can only be performed using `ALGORITHM=COPY`.

The `WITHOUT VALIDATION` and `WITH VALIDATION` clauses affect whether `ALTER TABLE` performs an in-place operation for [virtual generated column](#) modifications. See [Section 13.1.9.2, “ALTER TABLE and Generated Columns”](#).

NDB Cluster 8.0 supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. NDB does not support changing a tablespace online; beginning with NDB 8.0.21, it is disallowed. See [Section 22.5.11, “Online Operations with ALTER TABLE in NDB Cluster”](#), for more information.

`ALTER TABLE` with `DISCARD ... PARTITION ... TABLESPACE` or `IMPORT ... PARTITION ... TABLESPACE` does not create any temporary tables or temporary partition files.

`ALTER TABLE` with `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REBUILD PARTITION`, or `REORGANIZE PARTITION` does not create temporary tables (except when used with NDB tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between all partitions, unless `LINEAR HASH` or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

For `MyISAM` tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the `myisam_sort_buffer_size` system variable to a high value.

Concurrency Control

For `ALTER TABLE` operations that support it, you can use the `LOCK` clause to control the level of concurrent reads and writes on a table while it is being altered. Specifying a non-default value for this clause enables you to require a certain amount of concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available.

Only `LOCK = DEFAULT` is permitted for operations that use `ALGORITHM=INSTANT`. The other `LOCK` clause parameters are not applicable.

The parameters for the `LOCK` clause are:

- `LOCK = DEFAULT`

Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- `LOCK = NONE`

If supported, permit concurrent reads and writes. Otherwise, an error occurs.

- `LOCK = SHARED`

If supported, permit concurrent reads but block writes. Writes are blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, an error occurs.

- `LOCK = EXCLUSIVE`

Enforce exclusive access. This is done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.

Adding and Dropping Columns

Use `ADD` to add new columns to a table, and `DROP` to remove existing columns. `DROP col_name` is a MySQL extension to standard SQL.

To add a column at a specific position within a table row, use `FIRST` or `AFTER col_name`. The default is to add the column last.

If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use the `DROP TABLE` statement instead.

If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For `ALTER TABLE ... ADD`, if the column has an expression default value that uses a nondeterministic function, the statement may produce a warning or error. For further information, see [Section 11.6, “Data Type Default Values”](#), and [Section 17.1.3.6, “Restrictions on Replication with GTIDs”](#).

Renaming, Redefining, and Reordering Columns

The `CHANGE`, `MODIFY`, `RENAME COLUMN`, and `ALTER` clauses enable the names and definitions of existing columns to be altered. They have these comparative characteristics:

- `CHANGE`:
 - Can rename a column and change its definition, or both.
 - Has more capability than `MODIFY` or `RENAME COLUMN`, but at the expense of convenience for some operations. `CHANGE` requires naming the column twice if not renaming it, and requires respecifying the column definition if only renaming it.
 - With `FIRST` or `AFTER`, can reorder columns.
- `MODIFY`:
 - Can change a column definition but not its name.
 - More convenient than `CHANGE` to change a column definition without renaming it.
 - With `FIRST` or `AFTER`, can reorder columns.
- `RENAME COLUMN`:
 - Can change a column name but not its definition.
 - More convenient than `CHANGE` to rename a column without changing its definition.
- `ALTER`: Used only to change a column default value.

CHANGE is a MySQL extension to standard SQL. **MODIFY** and **RENAME COLUMN** are MySQL extensions for Oracle compatibility.

To alter a column to change both its name and definition, use **CHANGE**, specifying the old and new names and the new definition. For example, to rename an **INT NOT NULL** column from **a** to **b** and change its definition to use the **BIGINT** data type while retaining the **NOT NULL** attribute, do this:

```
ALTER TABLE t1 CHANGE a b BIGINT NOT NULL;
```

To change a column definition but not its name, use **CHANGE** or **MODIFY**. With **CHANGE**, the syntax requires two column names, so you must specify the same name twice to leave the name unchanged. For example, to change the definition of column **b**, do this:

```
ALTER TABLE t1 CHANGE b b INT NOT NULL;
```

MODIFY is more convenient to change the definition without changing the name because it requires the column name only once:

```
ALTER TABLE t1 MODIFY b INT NOT NULL;
```

To change a column name but not its definition, use **CHANGE** or **RENAME COLUMN**. With **CHANGE**, the syntax requires a column definition, so to leave the definition unchanged, you must respecify the definition the column currently has. For example, to rename an **INT NOT NULL** column from **b** to **a**, do this:

```
ALTER TABLE t1 CHANGE b a INT NOT NULL;
```

RENAME COLUMN is more convenient to change the name without changing the definition because it requires only the old and new names:

```
ALTER TABLE t1 RENAME COLUMN b TO a;
```

In general, you cannot rename a column to a name that already exists in the table. However, this is sometimes not the case, such as when you swap names or move them through a cycle. If a table has columns named **a**, **b**, and **c**, these are valid operations:

```
-- swap a and b
ALTER TABLE t1 RENAME COLUMN a TO b,
                RENAME COLUMN b TO a;
-- "rotate" a, b, c through a cycle
ALTER TABLE t1 RENAME COLUMN a TO b,
                RENAME COLUMN b TO c,
                RENAME COLUMN c TO a;
```

For column definition changes using **CHANGE** or **MODIFY**, the definition must include the data type and all attributes that should apply to the new column, other than index attributes such as **PRIMARY KEY** or **UNIQUE**. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column **col1** is defined as **INT UNSIGNED DEFAULT 1 COMMENT 'my column'** and you modify the column as follows, intending to change only **INT** to **BIGINT**:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

That statement changes the data type from **INT** to **BIGINT**, but it also drops the **UNSIGNED**, **DEFAULT**, and **COMMENT** attributes. To retain them, the statement must include them explicitly:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

For data type changes using **CHANGE** or **MODIFY**, MySQL tries to convert existing column values to the new type as well as possible.

Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from

succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using `ALTER TABLE` (see [Section 5.1.11](#), “Server SQL Modes”).

If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL automatically renames these references to the renamed column:

- Indexes that refer to the old column, including invisible indexes and disabled `MyISAM` indexes.
- Foreign keys that refer to the old column.

For columns renamed by `CHANGE` or `RENAME COLUMN`, MySQL does not automatically rename these references to the renamed column:

- Generated column and partition expressions that refer to the renamed column. You must use `CHANGE` to redefine such expressions in the same `ALTER TABLE` statement as the one that renames the column.
- Views and stored programs that refer to the renamed column. You must manually alter the definition of these objects to refer to the new column name.

To reorder columns within a table, use `FIRST` and `AFTER` in `CHANGE` or `MODIFY` operations.

`ALTER ... SET DEFAULT` or `ALTER ... DROP DEFAULT` specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be `NULL`, the new default is `NULL`. If the column cannot be `NULL`, MySQL assigns a default value as described in [Section 11.6](#), “Data Type Default Values”.

Primary Keys and Indexes

`DROP PRIMARY KEY` drops the [primary key](#). If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for `InnoDB` tables, see [Section 8.3.2](#), “Primary Key Optimization”.

If the `sql_require_primary_key` system variable is enabled, attempting to drop a primary key produces an error.

If you add a `UNIQUE INDEX` or `PRIMARY KEY` to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.

`DROP INDEX` removes an index. This is a MySQL extension to standard SQL. See [Section 13.1.27](#), “`DROP INDEX` Statement”. To determine index names, use `SHOW INDEX FROM tbl_name`.

Some storage engines permit you to specify an index type when creating an index. The syntax for the *index_type* specifier is `USING type_name`. For details about `USING`, see [Section 13.1.15](#), “`CREATE INDEX` Statement”. The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.

index_option values specify additional options for an index. `USING` is one such option. For details about permissible *index_option* values, see [Section 13.1.15](#), “`CREATE INDEX` Statement”.

`RENAME INDEX old_index_name TO new_index_name` renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. *old_index_name* must be the name of an existing index in the table that is not dropped by the same `ALTER TABLE` statement. *new_index_name* is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be `PRIMARY`.

If you use `ALTER TABLE` on a `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). This should make `ALTER TABLE` much faster when you have many indexes.

For [MyISAM](#) tables, key updating can be controlled explicitly. Use [ALTER TABLE ... DISABLE KEYS](#) to tell MySQL to stop updating nonunique indexes. Then use [ALTER TABLE ... ENABLE KEYS](#) to re-create missing indexes. [MyISAM](#) does this with a special algorithm that is much faster than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using [ALTER TABLE ... DISABLE KEYS](#) requires the [INDEX](#) privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as [SELECT](#) and [EXPLAIN](#) that otherwise would use them.

After an [ALTER TABLE](#) statement, it may be necessary to run [ANALYZE TABLE](#) to update index cardinality information. See [Section 13.7.7.22, “SHOW INDEX Statement”](#).

The [ALTER INDEX](#) operation permits an index to be made visible or invisible. An invisible index is not used by the optimizer. Modification of index visibility applies to indexes other than primary keys (either explicit or implicit). This feature is storage engine neutral (supported for any engine). For more information, see [Section 8.3.12, “Invisible Indexes”](#).

Foreign Keys and Other Constraints

The [FOREIGN KEY](#) and [REFERENCES](#) clauses are supported by the [InnoDB](#) and [NDB](#) storage engines, which implement [ADD \[CONSTRAINT \[symbol\]\] FOREIGN KEY \[index_name\] \(...\) REFERENCES ... \(...\)](#). See [Section 13.1.20.5, “FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored.

For [ALTER TABLE](#), unlike [CREATE TABLE](#), [ADD FOREIGN KEY](#) ignores [index_name](#) if given and uses an automatically generated foreign key name. As a workaround, include the [CONSTRAINT](#) clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...) ...
```

Important

MySQL silently ignores inline [REFERENCES](#) specifications, where the references are defined as part of the column specification. MySQL accepts only [REFERENCES](#) clauses defined as part of a separate [FOREIGN KEY](#) specification.

Note

Partitioned [InnoDB](#) tables do not support foreign keys. This restriction does not apply to [NDB](#) tables, including those explicitly partitioned by [\[LINEAR\] KEY](#). For more information, see [Section 23.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

MySQL Server and NDB Cluster both support the use of [ALTER TABLE](#) to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

Adding and dropping a foreign key in the same [ALTER TABLE](#) statement is supported for [ALTER TABLE ... ALGORITHM=INPLACE](#) but not for [ALTER TABLE ... ALGORITHM=COPY](#).

The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. A workaround is to use [ALTER TABLE ... DROP FOREIGN KEY](#) before changing the column definition and [ALTER TABLE ... ADD FOREIGN KEY](#) afterward. Examples of prohibited changes include:

- Changes to the data type of foreign key columns that may be unsafe. For example, changing [VARCHAR\(20\)](#) to [VARCHAR\(30\)](#) is permitted, but changing it to [VARCHAR\(1024\)](#) is not because that alters the number of length bytes required to store individual values.

- Changing a `NULL` column to `NOT NULL` in non-strict mode is prohibited to prevent converting `NULL` values to default non-`NULL` values, for which there are no corresponding values in the referenced table. The operation is permitted in strict mode, but an error is returned if any such conversion is required.

`ALTER TABLE tbl_name RENAME new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that begin with the string “`tbl_name_ibfk_`” to reflect the new table name. InnoDB interprets foreign key constraint names that begin with the string “`tbl_name_ibfk_`” as internally generated names.

Prior to MySQL 8.0.16, `ALTER TABLE` permits only the following limited version of `CHECK` constraint-adding syntax, which is parsed and ignored:

```
ADD CHECK (expr)
```

As of MySQL 8.0.16, `ALTER TABLE` permits `CHECK` constraints for existing tables to be added, dropped, or altered:

- Add a new `CHECK` constraint:

```
ALTER TABLE tbl_name
  ADD CONSTRAINT [symbol] CHECK (expr) [[NOT] ENFORCED];
```

The meaning of constraint syntax elements is the same as for `CREATE TABLE`. See [Section 13.1.20.6, “CHECK Constraints”](#).

- Drop an existing `CHECK` constraint named *symbol*:

```
ALTER TABLE tbl_name
  DROP CHECK symbol;
```

- Alter whether an existing `CHECK` constraint named *symbol* is enforced:

```
ALTER TABLE tbl_name
  ALTER CHECK symbol [NOT] ENFORCED;
```

The `DROP CHECK` and `ALTER CHECK` clauses are MySQL extensions to standard SQL.

As of MySQL 8.0.19, `ALTER TABLE` permits more general (and SQL standard) syntax for dropping and altering existing constraints of any type, where the constraint type is determined from the constraint name:

- Drop an existing constraint named *symbol*:

```
ALTER TABLE tbl_name
  DROP CONSTRAINT symbol;
```

If the `sql_require_primary_key` system variable is enabled, attempting to drop a primary key produces an error.

- Alter whether an existing constraint named *symbol* is enforced:

```
ALTER TABLE tbl_name
  ALTER CONSTRAINT symbol [NOT] ENFORCED;
```

Only `CHECK` constraints can be altered to be unenforced. All other constraint types are always enforced.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema, but constraints of different types can have the same name. When multiple constraints have the same name, `DROP CONSTRAINT` and `ADD CONSTRAINT` are ambiguous and an error occurs. In such cases, constraint-specific syntax must be used to modify the constraint. For example, use `DROP PRIMARY KEY` or `DROP FOREIGN KEY` to drop a primary key or foreign key.

If a table alteration causes a violation of an enforced [CHECK](#) constraint, an error occurs and the table is not modified. Examples of operations for which an error occurs:

- Attempts to add the [AUTO_INCREMENT](#) attribute to a column that is used in a [CHECK](#) constraint.
- Attempts to add an enforced [CHECK](#) constraint or enforce a nonenforced [CHECK](#) constraint for which existing rows violate the constraint condition.
- Attempts to modify, rename, or drop a column that is used in a [CHECK](#) constraint, unless that constraint is also dropped in the same statement. Exception: If a [CHECK](#) constraint refers only to a single column, dropping the column automatically drops the constraint.

`ALTER TABLE tbl_name RENAME new_tbl_name` changes internally generated and user-defined [CHECK](#) constraint names that begin with the string “*tbl_name_chk_*” to reflect the new table name. MySQL interprets [CHECK](#) constraint names that begin with the string “*tbl_name_chk_*” as internally generated names.

Changing the Character Set

To change the table default character set and all character columns ([CHAR](#), [VARCHAR](#), [TEXT](#)) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no [COLLATE](#) clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of [VARCHAR](#) or one of the [TEXT](#) types, [CONVERT TO CHARACTER SET](#) changes the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a [TEXT](#) column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a [latin1 TEXT](#) column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to [utf8](#), each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length does not fit in a [TEXT](#) column's length bytes, so MySQL converts the data type to [MEDIUMTEXT](#), which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a [VARCHAR](#) column might be converted to [MEDIUMTEXT](#).

To avoid data type changes of the type just described, do not use [CONVERT TO CHARACTER SET](#). Instead, use [MODIFY](#) to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify [CONVERT TO CHARACTER SET binary](#), the [CHAR](#), [VARCHAR](#), and [TEXT](#) columns are converted to their corresponding binary string types ([BINARY](#), [VARBINARY](#), [BLOB](#)). This means that the columns no longer will have a character set and a subsequent [CONVERT TO](#) operation will not apply to them.

If *charset_name* is [DEFAULT](#) in a [CONVERT TO CHARACTER SET](#) operation, the character set named by the `character_set_database` system variable is used.

Warning

The [CONVERT TO](#) operation converts column values between the original and named character sets. This is *not* what you want if you have a column in one character set (like [latin1](#)) but the stored values actually use some other, incompatible character set (like [utf8](#)). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When the `foreign_key_checks` system variable is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

Importing InnoDB Tables

An `InnoDB` table created in its own `file-per-table` tablespace can be imported from a backup or from another MySQL server instance using `DISCARD TABLESPACE` and `IMPORT TABLESPACE` clauses. See [Section 15.6.1.3, “Importing InnoDB Tables”](#).

Row Order for MyISAM Tables

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

Note

The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for `InnoDB` tables because `InnoDB` always orders table rows according to the `clustered index`.

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

Partitioning Options

`partition_options` signifies options that can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`, `DISCARD PARTITION`, `IMPORT PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `EXCHANGE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

For more information about partition options, see [Section 13.1.20, “CREATE TABLE Statement”](#), and [Section 13.1.9.1, “ALTER TABLE Partition Operations”](#). For information about and examples of `ALTER TABLE ... EXCHANGE PARTITION` statements, see [Section 23.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

13.1.9.1 ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, to add, drop, discard, import, merge, and split partitions, and to perform partitioning maintenance.

- Simply using a `partition_options` clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the `partition_options`. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the `partition_options` clause for `CREATE TABLE` (for more detailed information, see [Section 13.1.20, “CREATE TABLE Statement”](#)), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
  PARTITION BY HASH(id)
  PARTITIONS 8;
```

MySQL supports an `ALGORITHM` option with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Section 23.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See [Section 13.1.20, “CREATE TABLE Statement”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

DROP PARTITION can be used to drop one or more **RANGE** or **LIST** partitions. This statement cannot be used with **HASH** or **KEY** partitions; instead, use **COALESCE PARTITION** (see later in this section). Any data that was stored in the dropped partitions named in the *partition_names* list is discarded. For example, given the table *t1* defined previously, you can drop the partitions named *p0* and *p1* as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

Note

DROP PARTITION does not work with tables that use the **NDB** storage engine. See [Section 23.3.1, “Management of RANGE and LIST Partitions”](#), and [Section 22.1.7, “Known Limitations of NDB Cluster”](#).

ADD PARTITION and **DROP PARTITION** do not currently support **IF [NOT] EXISTS**.

The **DISCARD PARTITION ... TABLESPACE** and **IMPORT PARTITION ... TABLESPACE** options extend the [Transportable Tablespace](#) feature to individual **InnoDB** table partitions. Each **InnoDB** table partition has its own tablespace file (*.ibd* file). The [Transportable Tablespace](#) feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

```
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

```
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running **DISCARD PARTITION ... TABLESPACE** and **IMPORT PARTITION ... TABLESPACE** on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

The [Transportable Tablespace](#) feature also supports copying or restoring partitioned **InnoDB** tables. For more information, see [Section 15.6.1.3, “Importing InnoDB Tables”](#).

Renames of partitioned tables are supported. You can rename individual partitions indirectly using **ALTER TABLE ... REORGANIZE PARTITION**; however, this operation copies the partition's data.

To delete rows from selected partitions, use the **TRUNCATE PARTITION** option. This option takes a list of one or more comma-separated partition names. Consider the table *t1* created by this statement:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2003),
  PARTITION p4 VALUES LESS THAN (2007)
```

```
);
```

To delete all rows from partition `p0`, use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE` conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions `p1` and `p3`:

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```
DELETE FROM t1 WHERE
  (year_col >= 1991 AND year_col < 1995)
  OR
  (year_col >= 2003 AND year_col < 2007);
```

If you use the `ALL` keyword in place of the list of partition names, the statement acts on all table partitions.

`TRUNCATE PARTITION` merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

To verify that the rows were dropped, check the `INFORMATION_SCHEMA.PARTITIONS` table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 't1';
```

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by *number*. Suppose that you have created table `t2` as follows:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
PARTITIONS 6;
```

To reduce the number of partitions used by `t2` from 6 to 4, use the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions will be merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This is done by naming several partitions in the *partition_names* list and supplying a single definition for *partition_definition*.
- To split an existing partition into several partitions. Accomplish this by naming a single partition for *partition_names* and providing multiple *partition_definitions*.

- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.

**Note**

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see [Section 23.3.1, “Management of RANGE and LIST Partitions”](#).

- To exchange a table partition or subpartition with a table, use the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see [Section 23.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

- Several options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; for more information, see [Section 13.7.3, “Table Maintenance Statements”](#)). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a `partition_names` clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the target table. You can also use the `ALL` keyword in place of `partition_names`, in which case the statement acts on all table partitions. For more information and examples, see [Section 23.3.4, “Maintenance of Partitions”](#).

InnoDB does not currently support per-partition optimization; `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) To work around this problem, use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not supported for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.
- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning. The target storage engine must provide its own partitioning handler. Only the InnoDB and NDB storage engines have native partitioning handlers; NDB is not currently supported in MySQL 8.0.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see [Section 13.1.9.1, “ALTER TABLE Partition Operations”](#).

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE`

`PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

`REBUILD` operations are currently unsupported for subpartitions. The `REBUILD` keyword is expressly disallowed with subpartitions, and causes `ALTER TABLE` to fail with an error if so used.

`CHECK PARTITION` and `REPAIR PARTITION` operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see [Section 23.3.4, “Maintenance of Partitions”](#).

13.1.9.2 ALTER TABLE and Generated Columns

`ALTER TABLE` operations permitted for generated columns are `ADD`, `MODIFY`, and `CHANGE`.

- Generated columns can be added.

```
CREATE TABLE t1 (c1 INT);
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

- The data type and expression of generated columns can be modified.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 MODIFY COLUMN c2 TINYINT GENERATED ALWAYS AS (c1 + 5) STORED;
```

- Generated columns can be renamed or dropped, if no other column refers to them.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 CHANGE c2 c3 INT GENERATED ALWAYS AS (c1 + 1) STORED;
ALTER TABLE t1 DROP COLUMN c3;
```

- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) VIRTUAL);
ALTER TABLE t1 DROP COLUMN c2;
ALTER TABLE t1 ADD COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

- Nongenerated columns can be altered to stored but not virtual generated columns.

```
CREATE TABLE t1 (c1 INT, c2 INT);
ALTER TABLE t1 MODIFY COLUMN c2 INT GENERATED ALWAYS AS (c1 + 1) STORED;
```

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.

```
CREATE TABLE t1 (c1 INT, c2 INT GENERATED ALWAYS AS (c1 + 1) STORED);
ALTER TABLE t1 MODIFY COLUMN c2 INT;
```

- `ADD COLUMN` is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.
- For non-partitioned tables, `ADD COLUMN` and `DROP COLUMN` are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other `ALTER TABLE` operations.

For partitioned tables, `ADD COLUMN` and `DROP COLUMN` are not in-place operations for virtual columns.

- `InnoDB` supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see [Section 13.1.20.9, “Secondary Indexes and Generated Columns”](#).
- When a `VIRTUAL` generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression will not be out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, `ALTER TABLE` supports `WITHOUT VALIDATION` and `WITH VALIDATION` clauses:
 - With `WITHOUT VALIDATION` (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.
 - With `WITH VALIDATION`, `ALTER TABLE` copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.

`WITHOUT VALIDATION` and `WITH VALIDATION` are permitted only with `ADD COLUMN`, `CHANGE COLUMN`, and `MODIFY COLUMN` operations. Otherwise, an `ER_WRONG_USAGE` error occurs.

- If expression evaluation causes truncation or provides incorrect input to a function, the `ALTER TABLE` statement terminates with an error and the DDL operation is rejected.
- An `ALTER TABLE` statement that changes the default value of a column `col_name` may also change the value of a generated column expression that refers to the column using `col_name`, which may change the value of a generated column expression that refers to the column using `DEFAULT(col_name)`. For this reason, `ALTER TABLE` operations that change the definition of a column cause a table rebuild if any generated column expression uses `DEFAULT()`.

13.1.9.3 ALTER TABLE Examples

Begin with a table `t1` created as shown here:

```
CREATE TABLE t1 (a INTEGER, b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,  
ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

For `NDB` tables, it is also possible to change the storage type used for a table or column. For example, consider an `NDB` table created as shown here:

```
mysql> CREATE TABLE t1 (c1 INT) TABLESPACE ts_1 ENGINE NDB;  
Query OK, 0 rows affected (1.27 sec)
```

To convert this table to disk-based storage, you can use the following `ALTER TABLE` statement:

```
mysql> ALTER TABLE t1 TABLESPACE ts_1 STORAGE DISK;  
Query OK, 0 rows affected (2.99 sec)  
Records: 0 Duplicates: 0 Warnings: 0  
  
mysql> SHOW CREATE TABLE t1\G  
***** 1. row *****  
Table: t1  
Create Table: CREATE TABLE `t1` (  
  `c1` int(11) DEFAULT NULL  
) /*!50100 TABLESPACE ts_1 STORAGE DISK */  
ENGINE=ndbcluster DEFAULT CHARSET=latin1  
1 row in set (0.01 sec)
```

It is not necessary that the tablespace was referenced when the table was originally created; however, the tablespace must be referenced by the `ALTER TABLE`:

```
mysql> CREATE TABLE t2 (c1 INT) ts_1 ENGINE NDB;  
Query OK, 0 rows affected (1.00 sec)  
  
mysql> ALTER TABLE t2 STORAGE DISK;  
ERROR 1005 (HY000): Can't create table 'c.#sql-1750_3' (errno: 140)  
mysql> ALTER TABLE t2 TABLESPACE ts_1 STORAGE DISK;  
Query OK, 0 rows affected (3.42 sec)  
Records: 0 Duplicates: 0 Warnings: 0  
mysql> SHOW CREATE TABLE t2\G  
***** 1. row *****  
Table: t1  
Create Table: CREATE TABLE `t2` (  
  `c1` int(11) DEFAULT NULL  
) /*!50100 TABLESPACE ts_1 STORAGE DISK */  
ENGINE=ndbcluster DEFAULT CHARSET=latin1  
1 row in set (0.01 sec)
```

To change the storage type of an individual column, you can use `ALTER TABLE ... MODIFY [COLUMN]`. For example, suppose you create an `NDB Cluster Disk Data` table with two columns, using this `CREATE TABLE` statement:

```
mysql> CREATE TABLE t3 (c1 INT, c2 INT)  
->    TABLESPACE ts_1 STORAGE DISK ENGINE NDB;  
Query OK, 0 rows affected (1.34 sec)
```

To change column `c2` from disk-based to in-memory storage, include a `STORAGE MEMORY` clause in the column definition used by the `ALTER TABLE` statement, as shown here:

```
mysql> ALTER TABLE t3 MODIFY c2 INT STORAGE MEMORY;  
Query OK, 0 rows affected (3.14 sec)  
Records: 0 Duplicates: 0 Warnings: 0
```

You can make an in-memory column into a disk-based column by using `STORAGE DISK` in a similar fashion.

Column `c1` uses disk-based storage, since this is the default for the table (determined by the table-level `STORAGE DISK` clause in the `CREATE TABLE` statement). However, column `c2` uses in-memory storage, as can be seen here in the output of `SHOW CREATE TABLE`:

```
mysql> SHOW CREATE TABLE t3\G
***** 1. row *****
      Table: t3
Create Table: CREATE TABLE `t3` (
  `c1` int(11) DEFAULT NULL,
  `c2` int(11) /*!50120 STORAGE MEMORY */ DEFAULT NULL
) /*!50100 TABLESPACE ts_1 STORAGE DISK */ ENGINE=ndbcluster DEFAULT CHARSET=latin1
1 row in set (0.02 sec)
```

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option.

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the replica and the source. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the source and replica, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both source and replica, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;
ALTER TABLE t2 RENAME t1;
```

13.1.10 ALTER TABLESPACE Statement

```
ALTER [UNDO] TABLESPACE tablespace_name
  NDB only:
    {ADD | DROP} DATAFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
  InnoDB and NDB:
    [RENAME TO tablespace_name]
  InnoDB only:
    [SET {ACTIVE | INACTIVE}]
```

```
[ENCRYPTION [=] {'Y' | 'N'}]
InnoDB and NDB:
[ENGINE [=] engine_name]
Reserved for future use:
[ENGINE_ATTRIBUTE [=] 'string']
```

This statement is used with **NDB** and **InnoDB** tablespaces. It can be used to add a new data file to, or to drop a data file from an **NDB** tablespace. It can also be used to rename an **NDB** Cluster Disk Data tablespace, rename an **InnoDB** general tablespace, encrypt an **InnoDB** general tablespace, or mark an **InnoDB** undo tablespace as active or inactive.

The **UNDO** keyword, introduced in MySQL 8.0.14, is used with the **SET {ACTIVE | INACTIVE}** clause to mark an **InnoDB** undo tablespace as active or inactive. For more information, see [Section 15.6.3.4, “Undo Tablespaces”](#).

The **ADD DATAFILE** variant enables you to specify an initial size for an **NDB** Disk Data tablespace using an **INITIAL_SIZE** clause, where *size* is measured in bytes; the default value is 134217728 (128 MB). You may optionally follow *size* with a one-letter abbreviation for an order of magnitude, similar to those used in *my.cnf*. Generally, this is one of the letters **M** (megabytes) or **G** (gigabytes).

On 32-bit systems, the maximum supported value for **INITIAL_SIZE** is 4294967296 (4 GB). (Bug #29186)

INITIAL_SIZE is rounded, explicitly, as for **CREATE TABLESPACE**.

Once a data file has been created, its size cannot be changed; however, you can add more data files to an **NDB** tablespace using additional **ALTER TABLESPACE ... ADD DATAFILE** statements.

When **ALTER TABLESPACE ... ADD DATAFILE** is used with **ENGINE = NDB**, a data file is created on each Cluster data node, but only one row is generated in the **INFORMATION_SCHEMA.FILES** table. See the description of this table, as well as [Section 22.5.10.1, “NDB Cluster Disk Data Objects”](#), for more information. **ADD DATAFILE** is not supported with **InnoDB** tablespaces.

Using **DROP DATAFILE** with **ALTER TABLESPACE** drops the data file '*file_name*' from an **NDB** tablespace. You cannot drop a data file from a tablespace which is in use by any table; in other words, the data file must be empty (no extents used). See [Section 22.5.10.1, “NDB Cluster Disk Data Objects”](#). In addition, any data file to be dropped must previously have been added to the tablespace with **CREATE TABLESPACE** or **ALTER TABLESPACE**. **DROP DATAFILE** is not supported with **InnoDB** tablespaces.

WAIT is parsed but otherwise ignored. It is intended for future expansion.

The **ENGINE** clause, which specifies the storage engine used by the tablespace, is deprecated and will be removed in a future release. The tablespace storage engine is known by the data dictionary, making the **ENGINE** clause obsolete. If the storage engine is specified, it must match the tablespace storage engine defined in the data dictionary. The only values for *engine_name* compatible with **NDB** tablespaces are **NDB** and **NDBCLUSTER**.

RENAME TO operations are implicitly performed in **autocommit** mode, regardless of the **autocommit** setting.

A **RENAME TO** operation cannot be performed while **LOCK TABLES** or **FLUSH TABLES WITH READ LOCK** is in effect for tables that reside in the tablespace.

Exclusive **metadata locks** are taken on tables that reside in a general tablespace while the tablespace is renamed, which prevents concurrent DDL. Concurrent DML is supported.

The **CREATE TABLESPACE** privilege is required to rename an **InnoDB** general tablespace.

The **ENCRYPTION** clause enables or disables page-level data encryption for an **InnoDB** general tablespace or the **mysql** system tablespace. Encryption support for general tablespaces was introduced in MySQL 8.0.13. Encryption support for the **mysql** system tablespace was introduced in MySQL 8.0.16.

A keyring plugin must be installed and configured before encryption can be enabled.

As of MySQL 8.0.16, if the `table_encryption_privilege_check` variable is enabled, the `TABLE_ENCRYPTION_ADMIN` privilege is required to alter a general tablespace with an `ENCRYPTION` clause setting that differs from the `default_table_encryption` setting.

Enabling encryption for a general tablespace fails if any table in the tablespace belongs to a schema defined with `DEFAULT ENCRYPTION='N'`. Similarly, disabling encryption fails if any table in the general tablespace belongs to a schema defined with `DEFAULT ENCRYPTION='Y'`. The `DEFAULT ENCRYPTION` schema option was introduced in MySQL 8.0.16.

If an `ALTER TABLESPACE` statement executed on a general tablespace does not include an `ENCRYPTION` clause, the tablespace retains its current encryption status, regardless of the `default_table_encryption` setting.

When a general tablespace or the `mysql` system tablespace is encrypted, all tables residing in the tablespace are encrypted. Likewise, a table created in an encrypted tablespace is encrypted.

The `INPLACE` algorithm is used when altering the `ENCRYPTION` attribute of a general tablespace or the `mysql` system tablespace. The `INPLACE` algorithm permits concurrent DML on tables that reside in the tablespace. Concurrent DDL is blocked.

For more information, see [Section 15.13, “InnoDB Data-at-Rest Encryption”](#).

The `ENGINE_ATTRIBUTE` option (available as of MySQL 8.0.21) is used to specify tablespace attributes for primary storage engines. The option is reserved for future use.

Permitted values are a string literal containing a valid `JSON` document or an empty string (`''`). Invalid `JSON` is rejected.

```
ALTER TABLESPACE ts1 ENGINE_ATTRIBUTE='{"key": "value"}';
```

`ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

`ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table's storage engine is changed.

It is not permitted to alter an individual element of a JSON attribute value. You can only add or replace an attribute.

13.1.11 ALTER VIEW Statement

```
ALTER
[ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
[DEFINER = user]
[SQL SECURITY { DEFINER | INVOKER }]
VIEW view_name [(column_list)]
AS select_statement
[WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for `CREATE VIEW` see [Section 13.1.23, “CREATE VIEW Statement”](#)). This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is permitted only to the definer or users with the `SET_USER_ID` privilege (or the deprecated `SUPER` privilege).

13.1.12 CREATE DATABASE Statement

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
[create_option] ...

create_option: [DEFAULT] {
    CHARACTER SET [=] charset_name
```

```

| COLLATE [=] collation_name
| ENCRYPTION [=] {'Y' | 'N'}
}

```

CREATE DATABASE creates a database with the given name. To use this statement, you need the **CREATE** privilege for the database. **CREATE SCHEMA** is a synonym for **CREATE DATABASE**.

An error occurs if the database exists and you did not specify **IF NOT EXISTS**.

CREATE DATABASE is not permitted within a session that has an active **LOCK TABLES** statement.

Each *create_option* specifies a database characteristic. Database characteristics are stored in the data dictionary.

- The **CHARACTER SET** option specifies the default database character set. The **COLLATE** option specifies the default database collation. For information about character set and collation names, see [Chapter 10, Character Sets, Collations, Unicode](#).

To see the available character sets and collations, use the **SHOW CHARACTER SET** and **SHOW COLLATION** statements, respectively. See [Section 13.7.7.3, “SHOW CHARACTER SET Statement”](#), and [Section 13.7.7.4, “SHOW COLLATION Statement”](#).

- The **ENCRYPTION** option, introduced in MySQL 8.0.16, defines the default database encryption, which is inherited by tables created in the database. The permitted values are 'Y' (encryption enabled) and 'N' (encryption disabled). If the **ENCRYPTION** option is not specified, the value of the `default_table_encryption` system variable defines the default database encryption. If the `table_encryption_privilege_check` system variable is enabled, the **TABLE_ENCRYPTION_ADMIN** privilege is required to specify a default encryption setting that differs from the `default_table_encryption` setting. For more information, see [Defining an Encryption Default for Schemas and General Tablespace](#)s.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the **CREATE DATABASE** statement creates only a directory under the MySQL data directory. Rules for permissible database names are given in [Section 9.2, “Schema Object Names”](#). If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 9.2.4, “Mapping of Identifiers to File Names”](#).

Creating a database directory by manually creating a directory under the data directory (for example, with `mkdir`) is unsupported in MySQL 8.0.

When you create a database, let the server manage the directory and the files in it. Manipulating database directories and files directly can cause inconsistencies and unexpected results.

MySQL has no limit on the number of databases. The underlying file system may have a limit on the number of directories.

You can also use the `mysqladmin` program to create databases. See [Section 4.5.2, “mysqladmin — A MySQL Server Administration Program”](#).

13.1.13 CREATE EVENT Statement

```

CREATE
  [DEFINER = user]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'string']
  DO event_body;

schedule: {

```

```

    AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
  [STARTS timestamp [+ INTERVAL interval] ...]
  [ENDS timestamp [+ INTERVAL interval] ...]
}

interval:
    quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
              WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
              DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}

```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see [Section 24.4.2, “Event Scheduler Configuration”](#).

`CREATE EVENT` requires the `EVENT` privilege for the schema in which the event is to be created. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in [Section 24.6, “Stored Object Access Control”](#).

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```

CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;

```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case-sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 9.2, “Schema Object Names”](#).

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as '`user_name`'@'`host_name`', `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in [Section 24.6, “Stored Object Access Control”](#). Also see that section for additional information about event security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within an event body, the `CURRENT_USER` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see [Section 6.2.22, “SQL-Based Account Activity Auditing”](#).

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the *event_body* defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by *timestamp*, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
->     ON SCHEDULE AT '2006-02-10 23:59:00'
->     DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
        PRESERVE is set. The event was dropped immediately after
        creation.
```

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The *interval* portion consists of two parts, a quantity and a unit of time, and follows the syntax rules described in [Temporal Intervals](#), except that you cannot use any units keywords that involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an *interval* as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a *timestamp* value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a *timestamp* value that tells MySQL when the event should stop repeating. You may also use `+`

`INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone internally. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see [Section 24.4.4, “Event Metadata”](#). See also [Section 13.7.7.18, “SHOW EVENTS Statement”](#), and [Section 25.14, “The INFORMATION_SCHEMA EVENTS Table”](#).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the `DISABLE` keyword. Alternatively, you can use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 13.1.3, “ALTER EVENT Statement”](#)).

A third value may also appear in place of `ENABLE` or `DISABLE`; `DISABLE ON SLAVE` is set for the status of an event on a replica to indicate that the event was created on the replication source server and replicated to the replica, but is not executed on the replica. See [Section 17.5.1.16, “Replication of Invoked Features”](#).

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action statement for a scheduled event. (See [Section 24.8, “Restrictions on Stored Programs”](#).) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
ON SCHEDULE
  EVERY 1 HOUR
COMMENT 'Clears out sessions table each hour.'
DO
  DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, *regardless of the current server SQL mode when the event begins executing*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |

CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
BEGIN
    INSERT INTO site_activity.totals (time, total)
        SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
END |

delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See [Section 24.1, “Defining Stored Programs”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |

CREATE EVENT e
ON SCHEDULE
EVERY 5 SECOND
DO
BEGIN
    DECLARE v INTEGER;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;

    SET v = 0;

    WHILE v < 5 DO
        INSERT INTO t1 VALUES (0);
        UPDATE t2 SET s1 = s1 + 1;
        SET v = v + 1;
    END WHILE;
END |

delimiter ;
```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```
CREATE EVENT e_call_myproc
ON SCHEDULE
AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
```

```
DO CALL myproc(5, 27);
```

If an event's definer has privileges sufficient to set global system variables (see [Section 5.1.9.1, “System Variable Privileges”](#)), the event can read and write global variables. As granting such privileges entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see [Section 24.2.1, “Stored Routine Syntax”](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

13.1.14 CREATE FUNCTION Statement

The `CREATE FUNCTION` statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see [Section 13.1.17, “CREATE PROCEDURE and CREATE FUNCTION Statements”](#).
- For information about creating user-defined functions, see [Section 13.7.4.1, “CREATE FUNCTION Statement for User-Defined Functions”](#).

13.1.15 CREATE INDEX Statement

```
CREATE [UNIQUE | FULLTEXT | SPATIAL] INDEX index_name
    [index_type]
    ON tbl_name (key_part,...)
    [index_option]
    [algorithm_option | lock_option] ...

key_part: {col_name [(length)] | (expr)} [ASC | DESC]

index_option: {
    KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | {VISIBLE | INVISIBLE}
  | ENGINE_ATTRIBUTE [=] 'string'
  | SECONDARY_ENGINE_ATTRIBUTE [=] 'string'
}

index_type:
    USING {BTREE | HASH}

algorithm_option:
    ALGORITHM [=] {DEFAULT | INPLACE | COPY}

lock_option:
    LOCK [=] {DEFAULT | NONE | SHARED | EXCLUSIVE}
```

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 13.1.20, “CREATE TABLE Statement”](#). This guideline is especially important for InnoDB tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 13.1.9, “ALTER TABLE Statement”](#). `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

InnoDB supports secondary indexes on virtual columns. For more information, see [Section 13.1.20.9, “Secondary Indexes and Generated Columns”](#).

When the `innodb_stats_persistent` setting is enabled, run the `ANALYZE TABLE` statement for an InnoDB table after creating an index on that table.

Beginning with MySQL 8.0.17, the *expr* for a *key_part* specification can take the form `(CAST json_expression AS type ARRAY)` to create a multi-valued index on a `JSON` column. See [Multi-Valued Indexes](#).

An index specification of the form `(key_part1, key_part2, ...)` creates an index with multiple key parts. Index key values are formed by concatenating the values of the given key parts. For example `(col1, col2, col3)` specifies a multiple-column index with index keys consisting of values from `col1`, `col2`, and `col3`.

A *key_part* specification can end with `ASC` or `DESC` to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given. `ASC` and `DESC` are not permitted for `HASH` indexes. `ASC` and `DESC` are also not supported for multi-valued indexes. As of MySQL 8.0.12, `ASC` and `DESC` are not permitted for `SPATIAL` indexes.

The following sections describe different aspects of the `CREATE INDEX` statement:

- [Column Prefix Key Parts](#)
- [Functional Key Parts](#)
- [Unique Indexes](#)
- [Full-Text Indexes](#)
- [Multi-Valued Indexes](#)
- [Spatial Indexes](#)
- [Index Options](#)
- [Table Copying and Locking Options](#)

Column Prefix Key Parts

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` key parts.
- Prefixes *must* be specified for `BLOB` and `TEXT` key parts. Additionally, `BLOB` and `TEXT` columns can be indexed only for `InnoDB`, `MyISAM`, and `BLACKHOLE` tables.
- Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements are interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for `InnoDB` tables that use the `REDUNDANT` or `COMPACT` row format. The prefix length limit is 3072 bytes for `InnoDB` tables that use the `DYNAMIC` or `COMPRESSED` row format. For `MyISAM` tables, the prefix length limit is 1000 bytes. The `NDB` storage engine does not support prefixes (see [Section 22.1.7.6, “Unsupported or Missing Features in NDB Cluster”](#)).

If a specified index prefix exceeds the maximum column data type size, `CREATE INDEX` handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.

The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, lookups performed using this index should not be much slower than using an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Functional Key Parts

A “normal” index indexes column values or prefixes of column values. For example, in the following table, the index entry for a given `t1` row includes the full `col1` value and a prefix of the `col2` value consisting of its first 10 characters:

```
CREATE TABLE t1 (
  col1 VARCHAR(10),
  col2 VARCHAR(20),
  INDEX (col1, col2(10))
);
```

MySQL 8.0.13 and higher supports functional key parts that index expression values rather than column or column prefix values. Use of functional key parts enables indexing of values not stored directly in the table. Examples:

```
CREATE TABLE t1 (col1 INT, col2 INT, INDEX func_index ((ABS(col1))));
CREATE INDEX idx1 ON t1 ((col1 + col2));
CREATE INDEX idx2 ON t1 ((col1 + col2), (col1 - col2), col1);
ALTER TABLE t1 ADD INDEX ((col1 * 40) DESC);
```

An index with multiple key parts can mix nonfunctional and functional key parts.

`ASC` and `DESC` are supported for functional key parts.

Functional key parts must adhere to the following rules. An error occurs if a key part definition contains disallowed constructs.

- In index definitions, enclose expressions within parentheses to distinguish them from columns or column prefixes. For example, this is permitted; the expressions are enclosed within parentheses:

```
INDEX ((col1 + col2), (col3 - col4))
```

This produces an error; the expressions are not enclosed within parentheses:

```
INDEX (col1 + col2, col3 - col4)
```

- A functional key part cannot consist solely of a column name. For example, this is not permitted:

```
INDEX ((col1), (col2))
```

Instead, write the key parts as nonfunctional key parts, without parentheses:

```
INDEX (col1, col2)
```

- A functional key part expression cannot refer to column prefixes. For a workaround, see the discussion of `SUBSTRING()` and `CAST()` later in this section.
- Functional key parts are not permitted in foreign key specifications.

For `CREATE TABLE ... LIKE`, the destination table preserves functional key parts from the original table.

Functional indexes are implemented as hidden virtual generated columns, which has these implications:

- Each functional key part counts against the limit on total number of table columns; see [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).
- Functional key parts inherit all restrictions that apply to generated columns. Examples:
 - Only functions permitted for generated columns are permitted for functional key parts.
 - Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.

For more information about applicable restrictions, see [Section 13.1.20.8, “CREATE TABLE and Generated Columns”](#), and [Section 13.1.9.2, “ALTER TABLE and Generated Columns”](#).

- The virtual generated column itself requires no storage. The index itself takes up storage space as any other index.

UNIQUE is supported for indexes that include functional key parts. However, primary keys cannot include functional key parts. A primary key requires the generated column to be stored, but functional key parts are implemented as virtual generated columns, not stored generated columns.

SPATIAL and **FULLTEXT** indexes cannot have functional key parts.

If a table contains no primary key, **InnoDB** automatically promotes the first **UNIQUE NOT NULL** index to the primary key. This is not supported for **UNIQUE NOT NULL** indexes that have functional key parts.

Nonfunctional indexes raise a warning if there are duplicate indexes. Indexes that contain functional key parts do not have this feature.

To remove a column that is referenced by a functional key part, the index must be removed first. Otherwise, an error occurs.

Although nonfunctional key parts support a prefix length specification, this is not possible for functional key parts. The solution is to use **SUBSTRING()** (or **CAST()**, as described later in this section). For a functional key part containing the **SUBSTRING()** function to be used in a query, the **WHERE** clause must contain **SUBSTRING()** with the same arguments. In the following example, only the second **SELECT** is able to use the index because that is the only query in which the arguments to **SUBSTRING()** match the index specification:

```
CREATE TABLE tbl (
  coll LONGTEXT,
  INDEX idx1 ((SUBSTRING(coll, 1, 10)))
);
SELECT * FROM tbl WHERE SUBSTRING(coll, 1, 9) = '123456789';
SELECT * FROM tbl WHERE SUBSTRING(coll, 1, 10) = '1234567890';
```

Functional key parts enable indexing of values that cannot be indexed otherwise, such as **JSON** values. However, this must be done correctly to achieve the desired effect. For example, this syntax does not work:

```
CREATE TABLE employees (
  data JSON,
  INDEX ((data->>'$.name'))
);
```

The syntax fails because:

- The **->>** operator translates into **JSON_UNQUOTE(JSON_EXTRACT(...))**.
- **JSON_UNQUOTE()** returns a value with a data type of **LONGTEXT**, and the hidden generated column thus is assigned the same data type.
- MySQL cannot index **LONGTEXT** columns specified without a prefix length on the key part, and prefix lengths are not permitted in functional key parts.

To index the **JSON** column, you could try using the **CAST()** function as follows:

```
CREATE TABLE employees (
  data JSON,
  INDEX ((CAST(data->>'$.name' AS CHAR(30))))
);
```

The hidden generated column is assigned the `VARCHAR(30)` data type, which can be indexed. But this approach produces a new issue when trying to use the index:

- `CAST()` returns a string with the collation `utf8mb4_0900_ai_ci` (the server default collation).
- `JSON_UNQUOTE()` returns a string with the collation `utf8mb4_bin` (hard coded).

As a result, there is a collation mismatch between the indexed expression in the preceding table definition and the `WHERE` clause expression in the following query:

```
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The index is not used because the expressions in the query and the index differ. To support this kind of scenario for functional key parts, the optimizer automatically strips `CAST()` when looking for an index to use, but *only* if the collation of the indexed expression matches that of the query expression. For an index with a functional key part to be used, either of the following two solutions work (although they differ somewhat in effect):

- Solution 1. Assign the indexed expression the same collation as `JSON_UNQUOTE()`:

```
CREATE TABLE employees (
  data JSON,
  INDEX idx ((CAST(data->>"$.name" AS CHAR(30)) COLLATE utf8mb4_bin))
);
INSERT INTO employees VALUES
  ('{ "name": "james", "salary": 9000 }'),
  ('{ "name": "James", "salary": 10000 }'),
  ('{ "name": "Mary", "salary": 12000 }'),
  ('{ "name": "Peter", "salary": 8000 }');
SELECT * FROM employees WHERE data->>'$.name' = 'James';
```

The `->>` operator is the same as `JSON_UNQUOTE(JSON_EXTRACT(...))`, and `JSON_UNQUOTE()` returns a string with collation `utf8mb4_bin`. The comparison is thus case-sensitive, and only one row matches:

```
+-----+
| data |
+-----+
| {"name": "James", "salary": 10000} |
+-----+
```

- Solution 2. Specify the full expression in the query:

```
CREATE TABLE employees (
  data JSON,
  INDEX idx ((CAST(data->>"$.name" AS CHAR(30))))
);
INSERT INTO employees VALUES
  ('{ "name": "james", "salary": 9000 }'),
  ('{ "name": "James", "salary": 10000 }'),
  ('{ "name": "Mary", "salary": 12000 }'),
  ('{ "name": "Peter", "salary": 8000 }');
SELECT * FROM employees WHERE CAST(data->>'$.name' AS CHAR(30)) = 'James';
```

`CAST()` returns a string with collation `utf8mb4_0900_ai_ci`, so the comparison case-insensitive and two rows match:

```
+-----+
| data |
+-----+
| {"name": "james", "salary": 9000} |
| {"name": "James", "salary": 10000} |
+-----+
```

Be aware that although the optimizer supports automatically stripping `CAST()` with indexed generated columns, the following approach does not work because it produces a different result with and without an index (Bug#27337092):

```
mysql> CREATE TABLE employees (
      data JSON,
      generated_col VARCHAR(30) AS (CAST(data->>'$.name' AS CHAR(30)))
);
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> INSERT INTO employees (data)
      VALUES ('{"name": "james"}'), ('{"name": "James"}');
Query OK, 2 rows affected, 1 warning (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 1

mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-----+-----+
| data          | generated_col |
+-----+-----+
| {"name": "James"} | James        |
+-----+-----+
1 row in set (0.00 sec)

mysql> ALTER TABLE employees ADD INDEX idx (generated_col);
Query OK, 0 rows affected, 1 warning (0.03 sec)
Records: 0 Duplicates: 0 Warnings: 1

mysql> SELECT * FROM employees WHERE data->>'$.name' = 'James';
+-----+-----+
| data          | generated_col |
+-----+-----+
| {"name": "james"} | james        |
| {"name": "James"} | James        |
+-----+-----+
2 rows in set (0.01 sec)
```

Unique Indexes

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length. A **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in **SELECT** statements, as follows:

- `_rowid` refers to the **PRIMARY KEY** column if there is a **PRIMARY KEY** consisting of a single integer column. If there is a **PRIMARY KEY** but it does not consist of a single integer column, `_rowid` cannot be used.
- Otherwise, `_rowid` refers to the column in the first **UNIQUE NOT NULL** index if that index consists of a single integer column. If the first **UNIQUE NOT NULL** index does not consist of a single integer column, `_rowid` cannot be used.

Full-Text Indexes

FULLTEXT indexes are supported only for **InnoDB** and **MyISAM** tables and can include only **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.10, “Full-Text Search Functions”](#), for details of operation.

Multi-Valued Indexes

As of MySQL 8.0.17, **InnoDB** supports multi-valued indexes. A multi-valued index is a secondary index defined on a column that stores an array of values. A “normal” index has one index record for each data record (1:1). A multi-valued index can have multiple index records for a single data record (N:1).

Multi-valued indexes are intended for indexing [JSON](#) arrays. For example, a multi-valued index defined on the array of zip codes in the following JSON document creates an index record for each zip code, with each index record referencing the same data record.

```
{
  "user": "Bob",
  "user_id": 31,
  "zipcode": [94477, 94536]
}
```

Creating multi-valued Indexes

You can create a multi-valued index in a [CREATE TABLE](#), [ALTER TABLE](#), or [CREATE INDEX](#) statement. This requires using [CAST\(... AS ... ARRAY\)](#) in the index definition, which casts same-typed scalar values in a [JSON](#) array to an SQL data type array. A virtual column is then generated transparently with the values in the SQL data type array; finally, a functional index (also referred to as a virtual index) is created on the virtual column. It is the functional index defined on the virtual column of values from the SQL data type array that forms the multi-valued index.

The examples in the following list show the three different ways in which a multi-valued index [zips](#) can be created on an array [\\$.zipcode](#) on a [JSON](#) column [custinfo](#) in a table named [customers](#). In each case, the JSON array is cast to an SQL data type array of [UNSIGNED](#) integer values.

- [CREATE TABLE](#) only:

```
CREATE TABLE customers (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  custinfo JSON,
  INDEX zips( (CAST(custinfo->'$.zip' AS UNSIGNED ARRAY)) )
);
```

- [CREATE TABLE](#) plus [ALTER TABLE](#):

```
CREATE TABLE customers (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  custinfo JSON
);

ALTER TABLE customers ADD INDEX zips( (CAST(custinfo->'$.zip' AS UNSIGNED ARRAY)) );
```

- [CREATE TABLE](#) plus [CREATE INDEX](#):

```
CREATE TABLE customers (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  custinfo JSON
);

CREATE INDEX zips ON customers ( (CAST(custinfo->'$.zip' AS UNSIGNED ARRAY)) );
```

A multi-valued index can also be defined as part of a composite index. This example shows a composite index that includes two single-valued parts (for the [id](#) and [modified](#) columns), and one multi-valued part (for the [custinfo](#) column):

```
CREATE TABLE customers (
  id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  custinfo JSON
);

ALTER TABLE customers ADD INDEX comp(id, modified,
  (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
```

Only one multi-valued key part can be used in a composite index. The multi-valued key part may be used in any order relative to the other parts of the key. In other words, the [ALTER TABLE](#) statement

just shown could have used `comp(id, (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY), modified))` (or any other ordering) and still have been valid.

Using multi-valued Indexes

The optimizer uses a multi-valued index to fetch records when the following functions are specified in a `WHERE` clause:

- `MEMBER OF()`
- `JSON_CONTAINS()`
- `JSON_OVERLAPS()`

We can demonstrate this by creating and populating the `customers` table using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE customers (
->   id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   modified DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
->   custinfo JSON
-> );
Query OK, 0 rows affected (0.51 sec)

mysql> INSERT INTO customers VALUES
->   (NULL, NOW(), '{"user":"Jack","user_id":37,"zipcode":[94582,94536]}'),
->   (NULL, NOW(), '{"user":"Jill","user_id":22,"zipcode":[94568,94507,94582]}'),
->   (NULL, NOW(), '{"user":"Bob","user_id":31,"zipcode":[94477,94507]}'),
->   (NULL, NOW(), '{"user":"Mary","user_id":72,"zipcode":[94536]}'),
->   (NULL, NOW(), '{"user":"Ted","user_id":56,"zipcode":[94507,94582]}');
Query OK, 5 rows affected (0.07 sec)
Records: 5  Duplicates: 0  Warnings: 0
```

First we execute three queries on the `customers` table, one each using `MEMBER OF()`, `JSON_CONTAINS()`, and `JSON_OVERLAPS()`, with the result from each query shown here:

```
mysql> SELECT * FROM customers
->   WHERE 94507 MEMBER OF(custinfo->'$.zipcode');
+----+-----+-----+-----+
| id | modified          | custinfo                                     |
+----+-----+-----+-----+
| 2  | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
| 3  | 2019-06-29 22:23:12 | {"user": "Bob", "user_id": 31, "zipcode": [94477, 94507]} |
| 5  | 2019-06-29 22:23:12 | {"user": "Ted", "user_id": 56, "zipcode": [94507, 94582]} |
+----+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT * FROM customers
->   WHERE JSON_CONTAINS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+-----+-----+-----+
| id | modified          | custinfo                                     |
+----+-----+-----+-----+
| 2  | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
| 5  | 2019-06-29 22:23:12 | {"user": "Ted", "user_id": 56, "zipcode": [94507, 94582]} |
+----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT * FROM customers
->   WHERE JSON_OVERLAPS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+-----+-----+-----+
| id | modified          | custinfo                                     |
+----+-----+-----+-----+
| 1  | 2019-06-29 22:23:12 | {"user": "Jack", "user_id": 37, "zipcode": [94582, 94536]} |
| 2  | 2019-06-29 22:23:12 | {"user": "Jill", "user_id": 22, "zipcode": [94568, 94507, 94582]} |
| 3  | 2019-06-29 22:23:12 | {"user": "Bob", "user_id": 31, "zipcode": [94477, 94507]} |
| 5  | 2019-06-29 22:23:12 | {"user": "Ted", "user_id": 56, "zipcode": [94507, 94582]} |
+----+-----+-----+-----+
4 rows in set (0.00 sec)
```

Next, we run `EXPLAIN` on each of the previous three queries:

```
mysql> EXPLAIN SELECT * FROM customers
-> WHERE 94507 MEMBER OF(custinfo->'$.zipcode');
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | partitions | type | possible_keys | key | key_len | ref | rows | filtered |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | customers | NULL | ALL | NULL | NULL | NULL | NULL | 5 | 100.00 |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> EXPLAIN SELECT * FROM customers
-> WHERE JSON_CONTAINS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | partitions | type | possible_keys | key | key_len | ref | rows | filtered |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | customers | NULL | ALL | NULL | NULL | NULL | NULL | 5 | 100.00 |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> EXPLAIN SELECT * FROM customers
-> WHERE JSON_OVERLAPS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | partitions | type | possible_keys | key | key_len | ref | rows | filtered |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | customers | NULL | ALL | NULL | NULL | NULL | NULL | 5 | 100.00 |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.01 sec)
```

None of the three queries just shown are able to use any keys. To solve this problem, we can add a multi-valued index on the `zipcode` array in the `JSON` column (`custinfo`), like this:

```
mysql> ALTER TABLE customers
-> ADD INDEX zips( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)) );
Query OK, 0 rows affected (0.47 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

When we run the previous `EXPLAIN` statements again, we can now observe that the queries can (and do) use the index `zips` that was just created:

```
mysql> EXPLAIN SELECT * FROM customers
-> WHERE 94507 MEMBER OF(custinfo->'$.zipcode');
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | partitions | type | possible_keys | key | key_len | ref | rows | filtered |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | customers | NULL | ref | zips | zips | 9 | const | 1 | 100.00 |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> EXPLAIN SELECT * FROM customers
-> WHERE JSON_CONTAINS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | partitions | type | possible_keys | key | key_len | ref | rows | filtered |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | customers | NULL | range | zips | zips | 9 | NULL | 6 | 100.00 |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.00 sec)
```

```
mysql> EXPLAIN SELECT * FROM customers
-> WHERE JSON_OVERLAPS(custinfo->'$.zipcode', CAST('[94507,94582]' AS JSON));
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| id | select_type | table | partitions | type | possible_keys | key | key_len | ref | rows | filtered |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 1 | SIMPLE | customers | NULL | range | zips | zips | 9 | NULL | 6 | 100.00 |
+----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 row in set, 1 warning (0.01 sec)
```

A multi-valued index can be defined as a unique key. If defined as a unique key, attempting to insert a value already present in the multi-valued index returns a duplicate key error. If duplicate values are already present, attempting to add a unique multi-valued index fails, as shown here:

```
mysql> ALTER TABLE customers DROP INDEX zips;
Query OK, 0 rows affected (0.55 sec)
```

```

Records: 0  Duplicates: 0  Warnings: 0

mysql> ALTER TABLE customers
      -> ADD UNIQUE INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)));
ERROR 1062 (23000): Duplicate entry '[94507, ' for key 'customers.zips'
mysql> ALTER TABLE customers
      -> ADD INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)));
Query OK, 0 rows affected (0.36 sec)
Records: 0  Duplicates: 0  Warnings: 0

```

Characteristics of Multi-Valued Indexes

Multi-valued indexes have the additional characteristics listed here:

- DML operations that affect multi-valued indexes are handled in the same way as DML operations that affect a normal index, with the only difference being that there may be more than one insert or update for a single clustered index record.
- Nullability and multi-valued indexes:
 - If multi-valued key part has an empty array, no entries are added to the index, and the data record is not accessible by an index scan.
 - If multi-valued key part generation returns a `NULL` value, a single entry containing `NULL` is added to the multi-valued index. If the key part is defined as `NOT NULL`, an error is reported.
 - If the typed array column is set to `NULL`, the storage engine stores single record containing `NULL` that points to the data record.
 - `JSON` null values are not permitted in indexed arrays. If any returned value is `NULL`, it is treated as a JSON null and an `Invalid JSON value` error is reported.
- Because multi-valued indexes are virtual indexes on virtual columns, they must adhere to the same rules as secondary indexes on virtual generated columns.
- Index records are not added for empty arrays.

Limitations and Restrictions on Multi-valued Indexes

Multi-valued indexes are subject to the limitations and restrictions listed here:

- Only one multi-valued key part is permitted per multi-valued index. However, the `CAST(... AS ... ARRAY)` expression can refer to multiple arrays within a `JSON` document, as shown here:

```
CAST(data->'$.arr[*][*]' AS UNSIGNED ARRAY)
```

In this case, all values matching the JSON expression are stored in the index as a single flat array.

- An index with a multi-valued key part does not support ordering and therefore cannot be used as a primary key. For the same reason, a multi-valued index cannot be defined using the `ASC` or `DESC` keyword.
- A multi-valued index cannot be a covering index.
- The maximum number of values per record for a multi-valued index is determined by the amount of data that can be stored on a single undo log page, which is 65221 bytes (64K minus 315 bytes for overhead), which means that the maximum total length of key values is also 65221 bytes. The maximum number of keys depends on various factors, which prevents defining a specific limit. Tests have shown a multi-valued index to permit as many as 1604 integer keys per record, for example. When the limit is reached, an error similar to the following is reported: `ERROR 3905 (HY000): Exceeded max number of values per record for multi-valued index 'idx' by 1 value(s)`.

- The only type of expression that is permitted in a multi-valued key part is a [JSON](#) expression. The expression need not reference an existing element in a JSON document inserted into the indexed column, but must itself be syntactically valid.
- Because index records for the same clustered index record are dispersed throughout a multi-valued index, a multi-valued index does not support range scans or index-only scans.
- Multi-valued indexes are not permitted in foreign key specifications.
- Index prefixes cannot be defined for multi-valued indexes.
- Multi-valued indexes cannot be defined on data cast as [BINARY](#) (see the description of the [CAST\(\)](#) function).
- Online creation of a multi-value index is not supported, which means the operation uses [ALGORITHM=COPY](#). See [Performance and Space Requirements](#).
- Character sets and collations other than the following two combinations of character set and collation are not supported for multi-valued indexes:
 1. The [binary](#) character set with the default [binary](#) collation
 2. The [utf8mb4](#) character set with the default [utf8mb4_0900_as_cs](#) collation.
- As with other indexes on columns of [InnoDB](#) tables, a multi-valued index cannot be created with [USING HASH](#); attempting to do so results in a warning: `This storage engine does not support the HASH index algorithm, storage engine default was used instead.` ([USING BTREE](#) is supported as usual.)

Spatial Indexes

The [MyISAM](#), [InnoDB](#), [NDB](#), and [ARCHIVE](#) storage engines support spatial columns such as [POINT](#) and [GEOMETRY](#). (Section 11.4, “Spatial Data Types”, describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes on spatial columns are available according to the following rules.

Spatial indexes on spatial columns have these characteristics:

- Available only for [InnoDB](#) and [MyISAM](#) tables. Specifying [SPATIAL INDEX](#) for other storage engines results in an error.
- As of MySQL 8.0.12, an index on a spatial column *must* be a [SPATIAL](#) index. The [SPATIAL](#) keyword is thus optional but implicit for creating an index on a spatial column.
- Available for single spatial columns only. A spatial index cannot be created over multiple spatial columns.
- Indexed columns must be [NOT NULL](#).
- Column prefix lengths are prohibited. The full width of each column is indexed.
- Not permitted for a primary key or unique index.

Nonspatial indexes on spatial columns (created with [INDEX](#), [UNIQUE](#), or [PRIMARY KEY](#)) have these characteristics:

- Permitted for any storage engine that supports spatial columns except [ARCHIVE](#).
- Columns can be [NULL](#) unless the index is a primary key.
- The index type for a non-[SPATIAL](#) index depends on the storage engine. Currently, B-tree is used.
- Permitted for a column that can have [NULL](#) values only for [InnoDB](#), [MyISAM](#), and [MEMORY](#) tables.

Index Options

Following the key part list, index options can be given. An *index_option* value can be any of the following:

- *KEY_BLOCK_SIZE [=] value*

For *MyISAM* tables, *KEY_BLOCK_SIZE* optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A *KEY_BLOCK_SIZE* value specified for an individual index definition overrides a table-level *KEY_BLOCK_SIZE* value.

KEY_BLOCK_SIZE is not supported at the index level for *InnoDB* tables. See [Section 13.1.20, “CREATE TABLE Statement”](#).

- *index_type*

Some storage engines permit you to specify an index type when creating an index. For example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

[Table 13.1, “Index Types Per Storage Engine”](#) shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an *index_type* clause in index definitions.

Table 13.1 Index Types Per Storage Engine

Storage Engine	Permissible Index Types
<i>InnoDB</i>	<i>BTREE</i>
<i>MyISAM</i>	<i>BTREE</i>
<i>MEMORY/HEAP</i>	<i>HASH</i> , <i>BTREE</i>
<i>NDB</i>	<i>HASH</i> , <i>BTREE</i> (see note in text)

The *index_type* clause cannot be used for *FULLTEXT INDEX* or (prior to MySQL 8.0.12) *SPATIAL INDEX* specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes *BTREE* as a type name. As of MySQL 8.0.12, this is permitted only for *SPATIAL* indexes. Prior to 8.0.12, *BTREE* cannot be specified for any storage engine.

BTREE indexes are implemented by the *NDB* storage engine as T-tree indexes.

Note

For indexes on *NDB* table columns, the *USING* option can be specified only for a unique index or primary key. *USING HASH* prevents the creation of an ordered index; otherwise, creating a unique index or primary key on an *NDB* table automatically results in the creation of both an ordered index and a hash index, each of which indexes the same set of columns.

For unique indexes that include one or more *NULL* columns of an *NDB* table, the hash index can be used only to look up literal values, which means that *IS [NOT] NULL* conditions require a full scan of the table. One workaround is to make sure that a unique index using one or more *NULL* columns on such

a table is always created in such a way that it includes the ordered index; that is, avoid employing `USING HASH` when creating the index.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes `RTREE` as a type name, but currently this cannot be specified for any storage engine.

Note

Use of the `index_type` option before the `ON tbl_name` clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an `index_type` option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

The following tables show index characteristics for the storage engines that support the `index_type` option.

Table 13.2 InnoDB Storage Engine Index Characteristics

Index Class	Index Type	Stores NULL VALUES	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
Primary key	<code>BTREE</code>	No	No	N/A	N/A
Unique	<code>BTREE</code>	Yes	Yes	Index	Index
Key	<code>BTREE</code>	Yes	Yes	Index	Index
<code>FULLTEXT</code>	N/A	Yes	Yes	Table	Table
<code>SPATIAL</code>	N/A	No	No	N/A	N/A

Table 13.3 MyISAM Storage Engine Index Characteristics

Index Class	Index Type	Stores NULL VALUES	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
Primary key	<code>BTREE</code>	No	No	N/A	N/A
Unique	<code>BTREE</code>	Yes	Yes	Index	Index
Key	<code>BTREE</code>	Yes	Yes	Index	Index
<code>FULLTEXT</code>	N/A	Yes	Yes	Table	Table
<code>SPATIAL</code>	N/A	No	No	N/A	N/A

Table 13.4 MEMORY Storage Engine Index Characteristics

Index Class	Index Type	Stores NULL VALUES	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
Primary key	<code>BTREE</code>	No	No	N/A	N/A
Unique	<code>BTREE</code>	Yes	Yes	Index	Index
Key	<code>BTREE</code>	Yes	Yes	Index	Index
Primary key	<code>HASH</code>	No	No	N/A	N/A
Unique	<code>HASH</code>	Yes	Yes	Index	Index

Index Class	Index Type	Stores NULL VALUES	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
Key	HASH	Yes	Yes	Index	Index

Table 13.5 NDB Storage Engine Index Characteristics

Index Class	Index Type	Stores NULL VALUES	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
Primary key	BTREE	No	No	Index	Index
Unique	BTREE	Yes	Yes	Index	Index
Key	BTREE	Yes	Yes	Index	Index
Primary key	HASH	No	No	Table (see note 1)	Table (see note 1)
Unique	HASH	Yes	Yes	Table (see note 1)	Table (see note 1)
Key	HASH	Yes	Yes	Table (see note 1)	Table (see note 1)

Table note:

1. [USING HASH](#) prevents creation of an implicit ordered index.

- [WITH_PARSER parser_name](#)

This option can be used only with [FULLTEXT](#) indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. [InnoDB](#) and [MyISAM](#) support full-text parser plugins. See [Full-Text Parser Plugins](#) and [Writing Full-Text Parser Plugins](#) for more information.

- [COMMENT 'string'](#)

Index definitions can include an optional comment of up to 1024 characters.

The [MERGE_THRESHOLD](#) for index pages can be configured for individual indexes using the [index_option COMMENT](#) clause of the [CREATE INDEX](#) statement. For example:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

If the page-full percentage for an index page falls below the [MERGE_THRESHOLD](#) value when a row is deleted or when a row is shortened by an update operation, [InnoDB](#) attempts to merge the index page with a neighboring index page. The default [MERGE_THRESHOLD](#) value is 50, which is the previously hardcoded value.

[MERGE_THRESHOLD](#) can also be defined at the index level and table level using [CREATE TABLE](#) and [ALTER TABLE](#) statements. For more information, see [Section 15.8.11, “Configuring the Merge Threshold for Index Pages”](#).

- [VISIBLE, INVISIBLE](#)

Specify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Specification of index visibility applies to indexes other than primary keys (either explicit or implicit). For more information, see [Section 8.3.12, “Invisible Indexes”](#).

- [ENGINE_ATTRIBUTE](#) and [SECONDARY_ENGINE_ATTRIBUTE](#) options (available as of MySQL 8.0.21) are used to specify index attributes for primary and secondary storage engines. The options are reserved for future use.

Permitted values are a string literal containing a valid [JSON](#) document or an empty string ("). Invalid [JSON](#) is rejected.

```
CREATE INDEX i1 ON t1 (c1) ENGINE_ATTRIBUTE='{ "key": "value" }';
```

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table's storage engine is changed.

Table Copying and Locking Options

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 13.1.9, “ALTER TABLE Statement”](#)

NDB Cluster supports online operations using the same `ALGORITHM=INPLACE` syntax used with the standard MySQL Server. See [Section 22.5.11, “Online Operations with ALTER TABLE in NDB Cluster”](#), for more information.

13.1.16 CREATE LOGFILE GROUP Statement

```
CREATE LOGFILE GROUP logfile_group
  ADD UNDOFILE 'undo_file'
  [INITIAL_SIZE [=] initial_size]
  [UNDO_BUFFER_SIZE [=] undo_buffer_size]
  [REDO_BUFFER_SIZE [=] redo_buffer_size]
  [NODEGROUP [=] nodegroup_id]
  [WAIT]
  [COMMENT [=] 'string']
  ENGINE [=] engine_name
```

This statement creates a new log file group named *logfile_group* having a single UNDO file named '*undo_file*'. A `CREATE LOGFILE GROUP` statement has one and only one `ADD UNDOFILE` clause. For rules covering the naming of log file groups, see [Section 9.2, “Schema Object Names”](#).

Note

All NDB Cluster Disk Data objects share the same namespace. This means that *each Disk Data object* must be uniquely named (and not merely each Disk Data object of a given type). For example, you cannot have a tablespace and a log file group with the same name, or a tablespace and a data file with the same name.

There can be only one log file group per NDB Cluster instance at any given time.

The optional `INITIAL_SIZE` parameter sets the UNDO file's initial size; if not specified, it defaults to **128M** (128 megabytes). The optional `UNDO_BUFFER_SIZE` parameter sets the size used by the UNDO buffer for the log file group; The default value for `UNDO_BUFFER_SIZE` is **8M** (eight megabytes); this value cannot exceed the amount of system memory available. Both of these parameters are specified in bytes. You may optionally follow either or both of these with a one-letter abbreviation for an order of magnitude, similar to those used in `my.cnf`. Generally, this is one of the letters **M** (for megabytes) or **G** (for gigabytes).

Memory used for `UNDO_BUFFER_SIZE` comes from the global pool whose size is determined by the value of the `SharedGlobalMemory` data node configuration parameter. This includes any default value implied for this option by the setting of the `InitialLogFileGroup` data node configuration parameter.

The maximum permitted for `UNDO_BUFFER_SIZE` is 629145600 (600 MB).

On 32-bit systems, the maximum supported value for `INITIAL_SIZE` is 4294967296 (4 GB). (Bug #29186)

The minimum allowed value for `INITIAL_SIZE` is 1048576 (1 MB).

The `ENGINE` option determines the storage engine to be used by this log file group, with `engine_name` being the name of the storage engine. In MySQL 8.0, this must be `NDB` (or `NDBCLUSTER`). If `ENGINE` is not set, MySQL tries to use the engine specified by the `default_storage_engine` server system variable (formerly `storage_engine`). In any case, if the engine is not specified as `NDB` or `NDBCLUSTER`, the `CREATE LOGFILE GROUP` statement appears to succeed but actually fails to create the log file group, as shown here:

```
mysql> CREATE LOGFILE GROUP lg1
->      ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Error | 1478 | Table storage engine 'InnoDB' does not support the create option 'TABLESPACE or LOGFILE |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> DROP LOGFILE GROUP lg1 ENGINE = NDB;
ERROR 1529 (HY000): Failed to drop LOGFILE GROUP

mysql> CREATE LOGFILE GROUP lg1
->      ADD UNDOFILE 'undo.dat' INITIAL_SIZE = 10M
->      ENGINE = NDB;
Query OK, 0 rows affected (2.97 sec)
```

The fact that the `CREATE LOGFILE GROUP` statement does not actually return an error when a non-`NDB` storage engine is named, but rather appears to succeed, is a known issue which we hope to address in a future release of NDB Cluster.

`REDO_BUFFER_SIZE`, `NODEGROUP`, `WAIT`, and `COMMENT` are parsed but ignored, and so have no effect in MySQL 8.0. These options are intended for future expansion.

When used with `ENGINE [=] NDB`, a log file group and associated `UNDO` log file are created on each Cluster data node. You can verify that the `UNDO` files were created and obtain information about them by querying the `INFORMATION_SCHEMA.FILES` table. For example:

```
mysql> SELECT LOGFILE_GROUP_NAME, LOGFILE_GROUP_NUMBER, EXTRA
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE FILE_NAME = 'undo_10.dat';
+-----+-----+-----+
| LOGFILE_GROUP_NAME | LOGFILE_GROUP_NUMBER | EXTRA |
+-----+-----+-----+
| lg_3              | 11                   | CLUSTER_NODE=3 |
| lg_3              | 11                   | CLUSTER_NODE=4 |
+-----+-----+-----+
2 rows in set (0.06 sec)
```

`CREATE LOGFILE GROUP` is useful only with Disk Data storage for NDB Cluster. See [Section 22.5.10, “NDB Cluster Disk Data Tables”](#).

13.1.17 CREATE PROCEDURE and CREATE FUNCTION Statements

```
CREATE
[DEFINER = user]
PROCEDURE sp_name ([proc_parameter[,...]]
[characteristic ...] routine_body

CREATE
[DEFINER = user]
FUNCTION sp_name ([func_parameter[,...]])
RETURNS type
[characteristic ...] routine_body

proc_parameter:
[ IN | OUT | INOUT ] param_name type
```

```

func_parameter:
    param_name type

type:
    Any valid MySQL data type

characteristic: {
    COMMENT 'string'
    | LANGUAGE SQL
    | [NOT] DETERMINISTIC
    | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER | INVOKER }
}

routine_body:
    Valid SQL routine statement

```

These statements are used to create a stored routine (a stored procedure or function). That is, the specified routine becomes known to the server. By default, a stored routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See [Section 13.7.4.1, “CREATE FUNCTION Statement for User-Defined Functions”](#). A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See [Section 9.2.5, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see [Section 13.2.1, “CALL Statement”](#)). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE` privilege. If the `DEFINER` clause is present, the privileges required depend on the `user` value, as discussed in [Section 24.6, “Stored Object Access Control”](#). If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` privilege, as discussed in [Section 24.7, “Stored Program Binary Logging”](#).

By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 24.2.2, “Stored Routines and MySQL Privileges”](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value

from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `OUT` or `INOUT` parameter. If you are calling the procedure from within a trigger, you can also pass `NEW.col_name` as an `OUT` or `INOUT` parameter.

For information about the effect of unhandled conditions on procedure parameters, see [Section 13.6.7.8, “Condition Handling and OUT or INOUT Parameters”](#).

Routine parameters cannot be referenced in statements prepared within the routine; see [Section 24.8, “Restrictions on Stored Programs”](#).

The following example shows a simple stored procedure that, given a country code, counts the number of cities for that country that appear in the `city` table of the `world` database. The country code is passed using an `IN` parameter, and the city count is returned using an `OUT` parameter:

```
mysql> delimiter //
```

```
mysql> CREATE PROCEDURE citycount (IN country CHAR(3), OUT cities INT)
  BEGIN
    SELECT COUNT(*) INTO cities FROM world.city
    WHERE CountryCode = country;
  END//
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> delimiter ;
```

```
mysql> CALL citycount('JPN', @cities); -- cities in Japan
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT @cities;
+-----+
| @cities |
+-----+
|      248 |
+-----+
1 row in set (0.00 sec)
```

```
mysql> CALL citycount('FRA', @cities); -- cities in France
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT @cities;
+-----+
| @cities |
+-----+
|       40 |
+-----+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See [Section 24.1, “Defining Stored Programs”](#).

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member of set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
      RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by a `CHARACTER SET` specification.

The *routine_body* consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in [Section 13.6, “Compound Statement Syntax”](#). In practice, stored functions tend to use compound statements, unless the body consists of a single `RETURN` statement.

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see [Section 24.8, “Restrictions on Stored Programs”](#).

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 13.2.1, “CALL Statement”](#).

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, *regardless of the current server SQL mode when the routine begins executing*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See [Section 24.7, “Stored Program Binary Logging”](#).

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the source and replica.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.
- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If the `DEFINER` clause is present, the `user` value should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The permitted `user` values depend on the privileges you hold, as discussed in [Section 24.6, “Stored Object Access Control”](#). Also see that section for additional information about stored routine security.

If the `DEFINER` clause is omitted, the default definer is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

Within the body of a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, the `CURRENT_USER` function returns the routine's `DEFINER` value. For information about user auditing within stored routines, see [Section 6.2.22, “SQL-Based Account Activity Auditing”](#).

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` system table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
    SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
    SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if `CHARACTER SET` is included in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

If `CHARACTER SET` and `COLLATE` are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide an explicit `CHARACTER SET` and a `COLLATE` attribute for character data parameters.

If you alter the database default character set or collation, stored routines that are to use the new database defaults must be dropped and recreated.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see [Section 10.3.3, “Database Character Set and Collation”](#).

13.1.18 CREATE SERVER Statement

```
CREATE SERVER server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)

option: {
    HOST character-literal
  | DATABASE character-literal
  | USER character-literal
  | PASSWORD character-literal
  | SOCKET character-literal
  | OWNER character-literal
  | PORT numeric-literal
```

```
}
```

This statement creates the definition of a server for use with the [FEDERATED](#) storage engine. The [CREATE SERVER](#) statement creates a new row in the `servers` table in the `mysql` database. This statement requires the [SUPER](#) privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case-insensitive. You may specify the name as a quoted string.

The `wrapper_name` is an identifier and may be quoted with single quotation marks.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note

The [OWNER](#) option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The [CREATE SERVER](#) statement creates an entry in the `mysql.servers` table that can later be used with the [CREATE TABLE](#) statement when creating a [FEDERATED](#) table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '198.51.100.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a [FEDERATED](#) table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 16.8, “The FEDERATED Storage Engine”](#).

[CREATE SERVER](#) causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

[CREATE SERVER](#) is not written to the binary log, regardless of the logging format that is in use.

13.1.19 CREATE SPATIAL REFERENCE SYSTEM Statement

```
CREATE OR REPLACE SPATIAL REFERENCE SYSTEM
  srid srs_attribute ...

CREATE SPATIAL REFERENCE SYSTEM
  [IF NOT EXISTS]
  srid srs_attribute ...

srs_attribute: {
  NAME 'srs_name'
| DEFINITION 'definition'
| ORGANIZATION 'org_name' IDENTIFIED BY org_id
| DESCRIPTION 'description'
}

srid, org_id: 32-bit unsigned integer
```

This statement creates a [spatial reference system](#) (SRS) definition and stores it in the data dictionary. It requires the [SUPER](#) privilege. The resulting data dictionary entry can be inspected using the [INFORMATION_SCHEMA.ST_SPATIAL_REFERENCE_SYSTEMS](#) table.

SRID values must be unique, so if neither [OR REPLACE](#) nor [IF NOT EXISTS](#) is specified, an error occurs if an SRS definition with the given *srid* value already exists.

With [CREATE OR REPLACE](#) syntax, any existing SRS definition with the same SRID value is replaced, unless the SRID value is used by some column in an existing table. In that case, an error occurs. For example:

```
mysql> CREATE OR REPLACE SPATIAL REFERENCE SYSTEM 4326 ...;
ERROR 3716 (SR005): Can't modify SRID 4326. There is at
least one column depending on it.
```

To identify which column or columns use the SRID, use this query, replacing 4326 with the SRID of the definition you are trying to create:

```
SELECT * FROM INFORMATION_SCHEMA.ST_GEOMETRY_COLUMNS WHERE SRS_ID=4326;
```

With [CREATE ... IF NOT EXISTS](#) syntax, any existing SRS definition with the same SRID value causes the new definition to be ignored and a warning occurs.

SRID values must be in the range of 32-bit unsigned integers, with these restrictions:

- SRID 0 is a valid SRID but cannot be used with [CREATE SPATIAL REFERENCE SYSTEM](#).
- If the value is in a reserved SRID range, a warning occurs. Reserved ranges are [0, 32767] (reserved by EPSG), [60,000,000, 69,999,999] (reserved by EPSG), and [2,000,000,000, 2,147,483,647] (reserved by MySQL). EPSG stands for the [European Petroleum Survey Group](#).
- Users should not create SRSs with SRIDs in the reserved ranges. Doing so runs the risk that the SRIDs will conflict with future SRS definitions distributed with MySQL, with the result that the new system-provided SRSs are not installed for MySQL upgrades or that the user-defined SRSs are overwritten.

Attributes for the statement must satisfy these conditions:

- Attributes can be given in any order, but no attribute can be given more than once.
- The [NAME](#) and [DEFINITION](#) attributes are mandatory.
- The [NAME srs_name](#) attribute value must be unique. The combination of the [ORGANIZATION org_name](#) and [org_id](#) attribute values must be unique.
- The [NAME srs_name](#) attribute value and [ORGANIZATION org_name](#) attribute value cannot be empty or begin or end with whitespace.
- String values in attribute specifications cannot contain control characters, including newline.
- The following table shows the maximum lengths for string attribute values.

Table 13.6 CREATE SPATIAL REFERENCE SYSTEM Attribute Lengths

Attribute	Maximum Length (characters)
NAME	80
DEFINITION	4096
ORGANIZATION	256
DESCRIPTION	2048

Here is an example [CREATE SPATIAL REFERENCE SYSTEM](#) statement. The [DEFINITION](#) value is reformatted across multiple lines for readability. (For the statement to be legal, the value actually must be given on a single line.)

```
CREATE SPATIAL REFERENCE SYSTEM 4120
NAME 'Greek'
ORGANIZATION 'EPSG' IDENTIFIED BY 4120
DEFINITION
'GEOGCS[ "Greek", DATUM[ "Greek", SPHEROID[ "Bessel 1841",
6377397.155, 299.1528128, AUTHORITY[ "EPSG", "7004" ] ],
AUTHORITY[ "EPSG", "6120" ] ], PRIMEM[ "Greenwich", 0,
AUTHORITY[ "EPSG", "8901" ] ], UNIT[ "degree", 0.017453292519943278,
AUTHORITY[ "EPSG", "9122" ] ], AXIS[ "Lat", NORTH], AXIS[ "Lon", EAST],
AUTHORITY[ "EPSG", "4120" ] ]';
```

The grammar for SRS definitions is based on the grammar defined in *OpenGIS Implementation Specification: Coordinate Transformation Services*, Revision 1.00, OGC 01-009, January 12, 2001, Section 7.2. This specification is available at <http://www.opengeospatial.org/standards/ct>.

MySQL incorporates these changes to the specification:

- Only the `<horz cs>` production rule is implemented (that is, geographic and projected SRSs).
- There is an optional, nonstandard `<authority>` clause for `<parameter>`. This makes it possible to recognize projection parameters by authority instead of name.
- The specification does not make `AXIS` clauses mandatory in `GEOGCS` spatial reference system definitions. However, if there are no `AXIS` clauses, MySQL cannot determine whether a definition has axes in latitude-longitude order or longitude-latitude order. MySQL enforces the nonstandard requirement that each `GEOGCS` definition must include two `AXIS` clauses. One must be `NORTH` or `SOUTH`, and the other `EAST` or `WEST`. The `AXIS` clause order determines whether the definition has axes in latitude-longitude order or longitude-latitude order.
- SRS definitions may not contain newlines.

If an SRS definition specifies an authority code for the projection (which is recommended), an error occurs if the definition is missing mandatory parameters. In this case, the error message indicates what the problem is. The projection methods and mandatory parameters that MySQL supports are shown in [Table 13.7, “Supported Spatial Reference System Projection Methods”](#) and [Table 13.8, “Spatial Reference System Projection Parameters”](#).

For additional information about writing SRS definitions for MySQL, see [Geographic Spatial Reference Systems in MySQL 8.0](#) and [Projected Spatial Reference Systems in MySQL 8.0](#)

The following table shows the projection methods that MySQL supports. MySQL permits unknown projection methods but cannot check the definition for mandatory parameters and cannot convert spatial data to or from an unknown projection. For detailed explanations of how each projection works, including formulas, see [EPSG Guidance Note 7-2](#).

Table 13.7 Supported Spatial Reference System Projection Methods

EPSG Code	Projection Name	Mandatory Parameters (EPSG Codes)
1024	Popular Visualisation Pseudo Mercator	8801, 8802, 8806, 8807
1027	Lambert Azimuthal Equal Area (Spherical)	8801, 8802, 8806, 8807
1028	Equidistant Cylindrical	8823, 8802, 8806, 8807
1029	Equidistant Cylindrical (Spherical)	8823, 8802, 8806, 8807
1041	Krovak (North Orientated)	8811, 8833, 1036, 8818, 8819, 8806, 8807
1042	Krovak Modified	8811, 8833, 1036, 8818, 8819, 8806, 8807, 8617, 8618, 1026,

EPSG Code	Projection Name	Mandatory Parameters (EPSG Codes)
		1027, 1028, 1029, 1030, 1031, 1032, 1033, 1034, 1035
1043	Krovak Modified (North Orientated)	8811, 8833, 1036, 8818, 8819, 8806, 8807, 8617, 8618, 1026, 1027, 1028, 1029, 1030, 1031, 1032, 1033, 1034, 1035
1051	Lambert Conic Conformal (2SP Michigan)	8821, 8822, 8823, 8824, 8826, 8827, 1038
1052	Colombia Urban	8801, 8802, 8806, 8807, 1039
9801	Lambert Conic Conformal (1SP)	8801, 8802, 8805, 8806, 8807
9802	Lambert Conic Conformal (2SP)	8821, 8822, 8823, 8824, 8826, 8827
9803	Lambert Conic Conformal (2SP Belgium)	8821, 8822, 8823, 8824, 8826, 8827
9804	Mercator (variant A)	8801, 8802, 8805, 8806, 8807
9805	Mercator (variant B)	8823, 8802, 8806, 8807
9806	Cassini-Soldner	8801, 8802, 8806, 8807
9807	Transverse Mercator	8801, 8802, 8805, 8806, 8807
9808	Transverse Mercator (South Orientated)	8801, 8802, 8805, 8806, 8807
9809	Oblique Stereographic	8801, 8802, 8805, 8806, 8807
9810	Polar Stereographic (variant A)	8801, 8802, 8805, 8806, 8807
9811	New Zealand Map Grid	8801, 8802, 8806, 8807

SELECT ... (Some valid select or union statement)

```

CREATE TABLE creates a table with the given name. You must have the **CREATE** privilege for the table.

By default, tables are created in the default database, using the **InnoDB** storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

MySQL has no limit on the number of tables. The underlying file system may have a limit on the number of files that represent tables. Individual storage engines may impose engine-specific constraints. **InnoDB** permits up to 4 billion tables.

For information about the physical representation of a table, see [Section 13.1.20.1, “Files Created by CREATE TABLE”](#).

There are several aspects to the **CREATE TABLE** statement, described under the following topics in this section:

- [Table Name](#)
- [Temporary Tables](#)
- [Table Cloning and Copying](#)
- [Column Data Types and Attributes](#)

- [Indexes, Foreign Keys, and CHECK Constraints](#)
- [Table Options](#)
- [Table Partitioning](#)

Table Name

- *tbl_name*

The table name can be specified as *db_name.tbl_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

Rules for permissible table names are given in [Section 9.2, “Schema Object Names”](#).

- `IF NOT EXISTS`

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

Temporary Tables

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. For more information, see [Section 13.1.20.2, “CREATE TEMPORARY TABLE Statement”](#).

Table Cloning and Copying

- `LIKE`

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see [Section 13.1.20.3, “CREATE TABLE ... LIKE Statement”](#).

- `[AS] query_expression`

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see [Section 13.1.20.4, “CREATE TABLE ... SELECT Statement”](#).

- `IGNORE` | `REPLACE`

The `IGNORE` and `REPLACE` options indicate how to handle rows that duplicate unique key values when copying a table using a `SELECT` statement.

For more information, see [Section 13.1.20.4, “CREATE TABLE ... SELECT Statement”](#).

Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section 8.4.7, “Limits on Table Column Count and Row Size”](#).

- *data_type*

data_type represents the data type in a column definition. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see [Chapter 11, Data Types](#).

- Some attributes do not apply to all data types. `AUTO_INCREMENT` applies only to integer and floating-point types. Prior to MySQL 8.0.13, `DEFAULT` does not apply to the `BLOB`, `TEXT`, `GEOMETRY`, and `JSON` types.
- Character data types (`CHAR`, `VARCHAR`, the `TEXT` types, `ENUM`, `SET`, and any synonyms) can include `CHARACTER SET` to specify the character set for the column. `CHARSET` is a synonym for `CHARACTER SET`. A collation for the character set can be specified with the `COLLATE` attribute, along with any other attributes. For details, see [Chapter 10, Character Sets, Collations, Unicode](#). Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 8.0 interprets length specifications in character column definitions in characters. Lengths for `BINARY` and `VARBINARY` are in bytes.

- For `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length. `BLOB` and `TEXT` columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for `CHAR`, `VARCHAR`, and `TEXT` columns, and the first *length* bytes of each column value for `BINARY`, `VARBINARY`, and `BLOB` columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see [Section 13.1.15, “CREATE INDEX Statement”](#).

Only the `InnoDB` and `MyISAM` storage engines support indexing on `BLOB` and `TEXT` columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

If a specified index prefix exceeds the maximum column data type size, `CREATE TABLE` handles the index as follows:

- For a nonunique index, either an error occurs (if strict SQL mode is enabled), or the index length is reduced to lie within the maximum column data type size and a warning is produced (if strict SQL mode is not enabled).
- For a unique index, an error occurs regardless of SQL mode because reducing the index length might enable insertion of nonunique entries that do not meet the specified uniqueness requirement.
- `JSON` columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the `JSON` column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.
- `NOT NULL` | `NULL`

If neither `NULL` nor `NOT NULL` is specified, the column is treated as though `NULL` had been specified.

In MySQL 8.0, only the `InnoDB`, `MyISAM`, and `MEMORY` storage engines support indexes on columns that can have `NULL` values. In other cases, you must declare indexed columns as `NOT NULL` or an error results.

- **DEFAULT**

Specifies a default value for a column. For more information about default value handling, including the case that a column definition includes no explicit **DEFAULT** value, see [Section 11.6, “Data Type Default Values”](#).

If the **NO_ZERO_DATE** or **NO_ZERO_IN_DATE** SQL mode is enabled and a date-valued default is not correct according to that mode, **CREATE TABLE** produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with **NO_ZERO_IN_DATE** enabled, **CREATE TABLE DEFAULT '2010-00-00'** produces a warning.

- **AUTO_INCREMENT**

An integer or floating-point column can have the additional attribute **AUTO_INCREMENT**. When you insert a value of **NULL** (recommended) or **0** into an indexed **AUTO_INCREMENT** column, the column is set to the next sequence value. Typically this is *value*+1, where *value* is the largest value for the column currently in the table. **AUTO_INCREMENT** sequences begin with 1.

To retrieve an **AUTO_INCREMENT** value after inserting a row, use the **LAST_INSERT_ID()** SQL function or the **mysql_insert_id()** C API function. See [Section 12.16, “Information Functions”](#), and **mysql_insert_id()**.

If the **NO_AUTO_VALUE_ON_ZERO** SQL mode is enabled, you can store 0 in **AUTO_INCREMENT** columns as 0 without generating a new sequence value. See [Section 5.1.11, “Server SQL Modes”](#).

There can be only one **AUTO_INCREMENT** column per table, it must be indexed, and it cannot have a **DEFAULT** value. An **AUTO_INCREMENT** column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an **AUTO_INCREMENT** column that contains 0.

For **MyISAM** tables, you can specify an **AUTO_INCREMENT** secondary column in a multiple-column key. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

To make MySQL compatible with some ODBC applications, you can find the **AUTO_INCREMENT** value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that **sql_auto_is_null** variable is not set to 0. See [Section 5.1.8, “Server System Variables”](#).

For information about **InnoDB** and **AUTO_INCREMENT**, see [Section 15.6.1.6, “AUTO_INCREMENT Handling in InnoDB”](#). For information about **AUTO_INCREMENT** and MySQL Replication, see [Section 17.5.1.1, “Replication and AUTO_INCREMENT”](#).

- **COMMENT**

A comment for a column can be specified with the **COMMENT** option, up to 1024 characters long. The comment is displayed by the **SHOW CREATE TABLE** and **SHOW FULL COLUMNS** statements.

- **COLUMN_FORMAT**

In **NDB Cluster**, it is also possible to specify a data storage format for individual columns of **NDB** tables using **COLUMN_FORMAT**. Permissible column formats are **FIXED**, **DYNAMIC**, and **DEFAULT**. **FIXED** is used to specify fixed-width storage, **DYNAMIC** permits the column to be variable-width,

and `DEFAULT` causes the column to use fixed-width or variable-width storage as determined by the column's data type (possibly overridden by a `ROW_FORMAT` specifier).

For `NDB` tables, the default value for `COLUMN_FORMAT` is `FIXED`.

In `NDB Cluster`, the maximum possible offset for a column defined with `COLUMN_FORMAT=FIXED` is 8188 bytes. For more information and possible workarounds, see [Section 22.1.7.5, “Limits Associated with Database Objects in NDB Cluster”](#).

`COLUMN_FORMAT` currently has no effect on columns of tables using storage engines other than `NDB`. MySQL 8.0 silently ignores `COLUMN_FORMAT`.

- `ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` options (available as of MySQL 8.0.21) are used to specify column attributes for primary and secondary storage engines. The options are reserved for future use.

Permitted values are a string literal containing a valid `JSON` document or an empty string (`''`). Invalid `JSON` is rejected.

```
CREATE TABLE t1 (c1 INT ENGINE_ATTRIBUTE='{ "key": "value" }');
```

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values can be repeated without error. In this case, the last specified value is used.

`ENGINE_ATTRIBUTE` and `SECONDARY_ENGINE_ATTRIBUTE` values are not checked by the server, nor are they cleared when the table's storage engine is changed.

- `STORAGE`

For `NDB` tables, it is possible to specify whether the column is stored on disk or in memory by using a `STORAGE` clause. `STORAGE DISK` causes the column to be stored on disk, and `STORAGE MEMORY` causes in-memory storage to be used. The `CREATE TABLE` statement used must still include a `TABLESPACE` clause:

```
mysql> CREATE TABLE t1 (
->     c1 INT STORAGE DISK,
->     c2 INT STORAGE MEMORY
-> ) ENGINE NDB;
ERROR 1005 (HY000): Can't create table 'c.t1' (errno: 140)

mysql> CREATE TABLE t1 (
->     c1 INT STORAGE DISK,
->     c2 INT STORAGE MEMORY
-> ) TABLESPACE ts_1 ENGINE NDB;
Query OK, 0 rows affected (1.06 sec)
```

For `NDB` tables, `STORAGE DEFAULT` is equivalent to `STORAGE MEMORY`.

The `STORAGE` clause has no effect on tables using storage engines other than `NDB`. The `STORAGE` keyword is supported only in the build of `mysqld` that is supplied with `NDB Cluster`; it is not recognized in any other version of MySQL, where any attempt to use the `STORAGE` keyword causes a syntax error.

- `GENERATED ALWAYS`

Used to specify a generated column expression. For information about [generated columns](#), see [Section 13.1.20.8, “CREATE TABLE and Generated Columns”](#).

[Stored generated columns](#) can be indexed. `InnoDB` supports secondary indexes on [virtual generated columns](#). See [Section 13.1.20.9, “Secondary Indexes and Generated Columns”](#).

Indexes, Foreign Keys, and CHECK Constraints

Several keywords apply to creation of indexes, foreign keys, and `CHECK` constraints. For general background in addition to the following descriptions, see [Section 13.1.15, “CREATE INDEX Statement”](#), [Section 13.1.20.5, “FOREIGN KEY Constraints”](#), and [Section 13.1.20.6, “CHECK Constraints”](#).

- `CONSTRAINT symbol`

The `CONSTRAINT symbol` clause may be given to name a constraint. If the clause is not given, or a `symbol` is not included following the `CONSTRAINT` keyword, MySQL automatically generates a constraint name, with the exception noted below. The `symbol` value, if used, must be unique per schema (database), per constraint type. A duplicate `symbol` results in an error. See also the discussion about length limits of generated constraint identifiers at [Section 9.2.1, “Identifier Length Limits”](#).

Note

If the `CONSTRAINT symbol` clause is not given in a foreign key definition, or a `symbol` is not included following the `CONSTRAINT` keyword, MySQL uses the foreign key index name up to MySQL 8.0.15, and automatically generates a constraint name thereafter.

The SQL standard specifies that all types of constraints (primary key, unique index, foreign key, check) belong to the same namespace. In MySQL, each constraint type has its own namespace per schema. Consequently, names for each type of constraint must be unique per schema, but constraints of different types can have the same name.

- `PRIMARY KEY`

A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. The name of a `PRIMARY KEY` is always `PRIMARY`, which thus cannot be used as the name for any other kind of index.

If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

In `InnoDB` tables, keep the `PRIMARY KEY` short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See [Section 15.6.2.1, “Clustered and Secondary Indexes”](#).)

In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.

A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(key_part, ...)` clause.

If a table has a `PRIMARY KEY` or `UNIQUE NOT NULL` index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in `SELECT` statements, as described in [Unique Indexes](#).

In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 13.7.7.22, “SHOW INDEX Statement”](#).

- `KEY` | `INDEX`

KEY is normally a synonym for **INDEX**. The key attribute **PRIMARY KEY** can also be specified as just **KEY** when given in a column definition. This was implemented for compatibility with other database systems.

- **UNIQUE**

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**. If you specify a prefix value for a column in a **UNIQUE** index, the column values must be unique within the prefix length.

If a table has a **PRIMARY KEY** or **UNIQUE NOT NULL** index that consists of a single column that has an integer type, you can use `_rowid` to refer to the indexed column in **SELECT** statements, as described in [Unique Indexes](#).

- **FULLTEXT**

A **FULLTEXT** index is a special type of index used for full-text searches. Only the **InnoDB** and **MyISAM** storage engines support **FULLTEXT** indexes. They can be created only from **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.10, “Full-Text Search Functions”](#), for details of operation. A **WITH PARSER** clause can be specified as an *index_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for **FULLTEXT** indexes. **InnoDB** and **MyISAM** support full-text parser plugins. See [Full-Text Parser Plugins](#) and [Writing Full-Text Parser Plugins](#) for more information.

- **SPATIAL**

You can create **SPATIAL** indexes on spatial data types. Spatial types are supported only for **InnoDB** and **MyISAM** tables, and indexed columns must be declared as **NOT NULL**. See [Section 11.4, “Spatial Data Types”](#).

- **FOREIGN KEY**

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see *reference_definition*, and *reference_option*.

Partitioned tables employing the **InnoDB** storage engine do not support foreign keys. See [Section 23.6, “Restrictions and Limitations on Partitioning”](#), for more information.

- **CHECK**

The **CHECK** clause enables the creation of constraints to be checked for data values in table rows. See [Section 13.1.20.6, “CHECK Constraints”](#).

- *key_part*

- A *key_part* specification can end with **ASC** or **DESC** to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given.
- Prefixes, defined by the *length* attribute, can be up to 767 bytes long for **InnoDB** tables that use the **REDUNDANT** or **COMPACT** row format. The prefix length limit is 3072 bytes for **InnoDB** tables that use the **DYNAMIC** or **COMPRESSED** row format. For **MyISAM** tables, the prefix length limit is 1000 bytes.

Prefix *limits* are measured in bytes. However, prefix *lengths* for index specifications in **CREATE TABLE**, **ALTER TABLE**, and **CREATE INDEX** statements are interpreted as number of characters

for nonbinary string types ([CHAR](#), [VARCHAR](#), [TEXT](#)) and number of bytes for binary string types ([BINARY](#), [VARBINARY](#), [BLOB](#)). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- Beginning with MySQL 8.0.17, the *expr* for a *key_part* specification can take the form ([CAST json_path AS type ARRAY](#)) to create a multi-valued index on a [JSON](#) column. [Multi-Valued Indexes](#), provides detailed information regarding creation of, usage of, and restrictions and limitations on multi-valued indexes.
- index_type*

Some storage engines permit you to specify an index type when creating an index. The syntax for the *index_type* specifier is [USING type_name](#).

Example:

```
CREATE TABLE lookup
(id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for [USING](#) is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

- index_option*

index_option values specify additional options for an index.

- [KEY_BLOCK_SIZE](#)

For [MyISAM](#) tables, [KEY_BLOCK_SIZE](#) optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A [KEY_BLOCK_SIZE](#) value specified for an individual index definition overrides the table-level [KEY_BLOCK_SIZE](#) value.

For information about the table-level [KEY_BLOCK_SIZE](#) attribute, see [Table Options](#).

- [WITH PARSER](#)

The [WITH PARSER](#) option can only be used with [FULLTEXT](#) indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. [InnoDB](#) and [MyISAM](#) support full-text parser plugins. If you have a [MyISAM](#) table with an associated full-text parser plugin, you can convert the table to [InnoDB](#) using [ALTER TABLE](#).

- [COMMENT](#)

In MySQL 8.0, index definitions can include an optional comment of up to 1024 characters.

You can set the [InnoDB MERGE_THRESHOLD](#) value for an individual index using the *index_option COMMENT* clause. See [Section 15.8.11, “Configuring the Merge Threshold for Index Pages”](#).

- [ENGINE_ATTRIBUTE](#) and [SECONDARY_ENGINE_ATTRIBUTE](#) options (available as of MySQL 8.0.21) are used to specify index attributes for primary and secondary storage engines. The options are reserved for future use.

For more information about permissible *index_option* values, see [Section 13.1.15, “CREATE INDEX Statement”](#). For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

- *reference_definition*

For *reference_definition* syntax details and examples, see [Section 13.1.20.5, “FOREIGN KEY Constraints”](#).

[InnoDB](#) and [NDB](#) tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both [ON DELETE](#) and [ON UPDATE](#) actions on foreign keys are supported. For more detailed information and examples, see [Section 13.1.20.5, “FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the [FOREIGN KEY](#) and [REFERENCES](#) syntax in [CREATE TABLE](#) statements. See [Section 1.7.2.3, “FOREIGN KEY Constraint Differences”](#).

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including [InnoDB](#), recognizes or enforces the [MATCH](#) clause used in referential integrity constraint definitions. Use of an explicit [MATCH](#) clause will not have the specified effect, and also causes [ON DELETE](#) and [ON UPDATE](#) clauses to be ignored. For these reasons, specifying [MATCH](#) should be avoided.

The [MATCH](#) clause in the SQL standard controls how [NULL](#) values in a composite (multiple-column) foreign key are handled when comparing to a primary key. [InnoDB](#) essentially implements the semantics defined by [MATCH SIMPLE](#), which permit a foreign key to be all or partially [NULL](#). In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, [InnoDB](#) does not enforce any requirement that the referenced columns be declared [UNIQUE](#) or [NOT NULL](#). The handling of foreign key references to nonunique keys or keys that contain [NULL](#) values is not well defined for operations such as [UPDATE](#) or [DELETE CASCADE](#). You are advised to use foreign keys that reference only keys that are both [UNIQUE](#) (or [PRIMARY](#)) and [NOT NULL](#).

MySQL parses but ignores “inline [REFERENCES](#) specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts [REFERENCES](#) clauses only when specified as part of a separate [FOREIGN KEY](#) specification.

- *reference_option*

For information about the [RESTRICT](#), [CASCADE](#), [SET NULL](#), [NO ACTION](#), and [SET DEFAULT](#) options, see [Section 13.1.20.5, “FOREIGN KEY Constraints”](#).

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use [ALTER TABLE](#) to convert the table to use a different storage engine.

- [ENGINE](#)

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name `'DEFAULT'` is recognized but ignored.

Storage Engine	Description
InnoDB	Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 15, The InnoDB Storage Engine , and in particular Section 15.1, “Introduction to InnoDB” if you have MySQL experience but are new to InnoDB.
MyISAM	The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 16.2, “The MyISAM Storage Engine” .
MEMORY	The data for this storage engine is stored only in memory. See Section 16.3, “The MEMORY Storage Engine” .
CSV	Tables that store rows in comma-separated values format. See Section 16.4, “The CSV Storage Engine” .
ARCHIVE	The archiving storage engine. See Section 16.5, “The ARCHIVE Storage Engine” .
EXAMPLE	An example engine. See Section 16.9, “The EXAMPLE Storage Engine” .
FEDERATED	Storage engine that accesses remote tables. See Section 16.8, “The FEDERATED Storage Engine” .
HEAP	This is a synonym for MEMORY.
MERGE	A collection of MyISAM tables used as one table. Also known as MRG_MyISAM. See Section 16.7, “The MERGE Storage Engine” .
NDB	Clustered, fault-tolerant, memory-based tables, supporting transactions and foreign keys. Also known as NDBCLUSTER. See Chapter 22, MySQL NDB Cluster 8.0 .

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing `NO_ENGINE_SUBSTITUTION` from the server SQL mode (see [Section 5.1.11, “Server SQL Modes”](#)) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is InnoDB, which is the default value for the `default_storage_engine` system variable. When `NO_ENGINE_SUBSTITUTION` is disabled, a warning occurs if the storage engine specification is not honored.

- AUTO_INCREMENT**

The initial `AUTO_INCREMENT` value for the table. In MySQL 8.0, this works for MyISAM, MEMORY, InnoDB, and ARCHIVE tables. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- AVG_ROW_LENGTH**

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a MyISAM table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for MyISAM data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system

variable. (See [Section 5.1.8, “Server System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- **[DEFAULT] CHARACTER SET**

Specifies a default character set for the table. **CHARSET** is a synonym for **CHARACTER SET**. If the character set name is **DEFAULT**, the database character set is used.

- **CHECKSUM**

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The **CHECKSUM TABLE** statement reports the checksum. (**MyISAM** only.)

- **[DEFAULT] COLLATE**

Specifies a default collation for the table.

- **COMMENT**

A comment for the table, up to 2048 characters long.

You can set the **InnoDB MERGE_THRESHOLD** value for a table using the *table_option* **COMMENT** clause. See [Section 15.8.11, “Configuring the Merge Threshold for Index Pages”](#).

Setting NDB_TABLE options. The table comment in a **CREATE TABLE** that creates an **NDB** table or an **ALTER TABLE** statement which alters one can also be used to specify one to four of the **NDB_TABLE** options **NOLOGGING**, **READ_BACKUP**, **PARTITION_BALANCE**, or **FULLY_REPLICATED** as a set of name-value pairs, separated by commas if need be, immediately following the string **NDB_TABLE=** that begins the quoted comment text. An example statement using this syntax is shown here (emphasized text):

```
CREATE TABLE t1 (
  c1 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  c2 VARCHAR(100),
  c3 VARCHAR(100) )
ENGINE=NDB
COMMENT="NDB_TABLE=READ_BACKUP=0 , PARTITION_BALANCE=FOR_RP_BY_NODE" ;
```

Spaces are not permitted within the quoted string. The string is case-insensitive.

The comment is displayed as part of the output of **SHOW CREATE TABLE**. The text of the comment is also available as the **TABLE_COMMENT** column of the MySQL Information Schema **TABLES** table.

This comment syntax is also supported with **ALTER TABLE** statements for **NDB** tables. Keep in mind that a table comment used with **ALTER TABLE** replaces any existing comment which the table might have had perviously.

Setting the **MERGE_THRESHOLD** option in table comments is not supported for **NDB** tables (it is ignored).

For complete syntax information and examples, see [Section 13.1.20.10, “Setting NDB_TABLE Options”](#).

- **COMPRESSION**

The compression algorithm used for page level compression for **InnoDB** tables. Supported values include **Zlib**, **LZ4**, and **None**. The **COMPRESSION** attribute was introduced with the transparent page compression feature. Page compression is only supported with **InnoDB** tables that reside in **file-per-**

[table](#) tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see [Section 15.9.2, “InnoDB Page Compression”](#).

- [CONNECTION](#)

The connection string for a [FEDERATED](#) table.

Note

Older versions of MySQL used a [COMMENT](#) option for the connection string.

- [DATA DIRECTORY](#), [INDEX DIRECTORY](#)

For [InnoDB](#), the [DATA DIRECTORY='directory'](#) clause permits creating tables outside of the data directory. The [innodb_file_per_table](#) variable must be enabled to use the [DATA DIRECTORY](#) clause. The full directory path must be specified. As of MySQL 8.0.21, the directory specified must be known to [InnoDB](#). For more information, see [Section 15.6.1.2, “Creating Tables Externally”](#).

When creating [MyISAM](#) tables, you can use the [DATA DIRECTORY='directory'](#) clause, the [INDEX DIRECTORY='directory'](#) clause, or both. They specify where to put a [MyISAM](#) table's data file and index file, respectively. Unlike [InnoDB](#) tables, MySQL does not create subdirectories that correspond to the database name when creating a [MyISAM](#) table with a [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) option. Files are created in the directory that is specified.

You must have the [FILE](#) privilege to use the [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) table option.

Important

Table-level [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the [--skip-symbolic-links](#) option. Your operating system must also have a working, thread-safe [realpath\(\)](#) call. See [Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”](#), for more complete information.

If a [MyISAM](#) table is created with no [DATA DIRECTORY](#) option, the [.MYD](#) file is created in the database directory. By default, if [MyISAM](#) finds an existing [.MYD](#) file in this case, it overwrites it. The same applies to [.MYI](#) files for tables created with no [INDEX DIRECTORY](#) option. To suppress this behavior, start the server with the [--keep_files_on_create](#) option, in which case [MyISAM](#) will not overwrite existing files and returns an error instead.

If a [MyISAM](#) table is created with a [DATA DIRECTORY](#) or [INDEX DIRECTORY](#) option and an existing [.MYD](#) or [.MYI](#) file is found, [MyISAM](#) always returns an error. It will not overwrite a file in the specified directory.

Important

You cannot use path names that contain the MySQL data directory with [DATA DIRECTORY](#) or [INDEX DIRECTORY](#). This includes partitioned tables and individual table partitions. (See Bug #32167.)

- [DELAY_KEY_WRITE](#)

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the [delay_key_write](#) system variable in [Section 5.1.8, “Server System Variables”](#). ([MyISAM](#) only.)

- [ENCRYPTION](#)

The [ENCRYPTION](#) clause enables or disables page-level data encryption for an [InnoDB](#) table. A keyring plugin must be installed and configured before encryption can be enabled. Prior to MySQL 8.0.16, the [ENCRYPTION](#) clause can only be specified when creating a table in an a file-per-table tablespace. As of MySQL 8.0.16, the [ENCRYPTION](#) clause can also be specified when creating a table in a general tablespace.

As of MySQL 8.0.16, a table inherits the default schema encryption if an [ENCRYPTION](#) clause is not specified. If the [table_encryption_privilege_check](#) variable is enabled, the [TABLE_ENCRYPTION_ADMIN](#) privilege is required to create a table with an [ENCRYPTION](#) clause setting that differs from the default schema encryption. When creating a table in a general tablespace, table and tablespace encryption must match.

As of MySQL 8.0.16, specifying an [ENCRYPTION](#) clause with a value other than 'N' or '' is not permitted when using a storage engine that does not support encryption. Previously, the clause was accepted.

For more information, see [Section 15.13, “InnoDB Data-at-Rest Encryption”](#).

- [ENGINE_ATTRIBUTE](#) and [SECONDARY_ENGINE_ATTRIBUTE](#) options (available as of MySQL 8.0.21) are used to specify table attributes for primary and secondary storage engines. The options are reserved for future use.

Permitted values are a string literal containing a valid [JSON](#) document or an empty string (''). Invalid [JSON](#) is rejected.

```
CREATE TABLE t1 (c1 INT) ENGINE_ATTRIBUTE='{ "key": "value" }';
```

[ENGINE_ATTRIBUTE](#) and [SECONDARY_ENGINE_ATTRIBUTE](#) values can be repeated without error. In this case, the last specified value is used.

[ENGINE_ATTRIBUTE](#) and [SECONDARY_ENGINE_ATTRIBUTE](#) values are not checked by the server, nor are they cleared when the table's storage engine is changed.

- [INSERT_METHOD](#)

If you want to insert data into a [MERGE](#) table, you must specify with [INSERT_METHOD](#) the table into which the row should be inserted. [INSERT_METHOD](#) is an option useful for [MERGE](#) tables only. Use a value of [FIRST](#) or [LAST](#) to have inserts go to the first or last table, or a value of [NO](#) to prevent inserts. See [Section 16.7, “The MERGE Storage Engine”](#).

- [KEY_BLOCK_SIZE](#)

For [MyISAM](#) tables, [KEY_BLOCK_SIZE](#) optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A [KEY_BLOCK_SIZE](#) value specified for an individual index definition overrides the table-level [KEY_BLOCK_SIZE](#) value.

For [InnoDB](#) tables, [KEY_BLOCK_SIZE](#) specifies the [page](#) size in kilobytes to use for [compressed InnoDB](#) tables. The [KEY_BLOCK_SIZE](#) value is treated as a hint; a different size could be used by [InnoDB](#) if necessary. [KEY_BLOCK_SIZE](#) can only be less than or equal to the [innodb_page_size](#) value. A value of 0 represents the default compressed page size, which is half of the [innodb_page_size](#) value. Depending on [innodb_page_size](#), possible [KEY_BLOCK_SIZE](#) values include 0, 1, 2, 4, 8, and 16. See [Section 15.9.1, “InnoDB Table Compression”](#) for more information.

Oracle recommends enabling [innodb_strict_mode](#) when specifying [KEY_BLOCK_SIZE](#) for [InnoDB](#) tables. When [innodb_strict_mode](#) is enabled, specifying an invalid [KEY_BLOCK_SIZE](#) value returns an error. If [innodb_strict_mode](#) is disabled, an invalid [KEY_BLOCK_SIZE](#) value results in a warning, and the [KEY_BLOCK_SIZE](#) option is ignored.

The `Create_options` column in response to `SHOW TABLE STATUS` reports the actual `KEY_BLOCK_SIZE` used by the table, as does `SHOW CREATE TABLE`.

InnoDB only supports `KEY_BLOCK_SIZE` at the table level.

`KEY_BLOCK_SIZE` is not supported with 32KB and 64KB `innodb_page_size` values. InnoDB table compression does not support these pages sizes.

InnoDB does not support the `KEY_BLOCK_SIZE` option when creating temporary tables.

- `MAX_ROWS`

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

Important

The use of `MAX_ROWS` with NDB tables to control the number of table partitions is deprecated. It remains supported in later versions for backward compatibility, but is subject to removal in a future release. Use `PARTITION_BALANCE` instead; see [Setting NDB_TABLE options](#).

The NDB storage engine treats this value as a maximum. If you plan to create very large NDB Cluster tables (containing millions of rows), you should use this option to insure that NDB allocates sufficient number of index slots in the hash table used for storing hashes of the table's primary keys by setting `MAX_ROWS = 2 * rows`, where `rows` is the number of rows that you expect to insert into the table.

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table. The MEMORY storage engine uses this option as a hint about memory use.

- `PACK_KEYS`

Takes effect only with MyISAM tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

This option is unused.

- `ROW_FORMAT`

Defines the physical format in which the rows are stored.

When creating a table with [strict mode](#) disabled, the storage engine's default row format is used if the specified row format is not supported. The actual row format of the table is reported in the `Row_format` column in response to `SHOW TABLE STATUS`. The `Create_options` column shows the row format that was specified in the `CREATE TABLE` statement, as does `SHOW CREATE TABLE`.

Row format choices differ depending on the storage engine used for the table.

For [InnoDB](#) tables:

- The default row format is defined by `innodb_default_row_format`, which has a default setting of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` option is not defined or when `ROW_FORMAT=DEFAULT` is used.

If the `ROW_FORMAT` option is not defined, or if `ROW_FORMAT=DEFAULT` is used, operations that rebuild a table also silently change the row format of the table to the default defined by `innodb_default_row_format`. For more information, see [Defining the Row Format of a Table](#).

- For more efficient [InnoDB](#) storage of data types, especially `BLOB` types, use the `DYNAMIC`. See [DYNAMIC Row Format](#) for requirements associated with the `DYNAMIC` row format.
- To enable compression for [InnoDB](#) tables, specify `ROW_FORMAT=COMPRESSED`. The `ROW_FORMAT=COMPRESSED` option is not supported when creating temporary tables. See [Section 15.9, “InnoDB Table and Page Compression”](#) for requirements associated with the `COMPRESSED` row format.
- The row format used in older versions of MySQL can still be requested by specifying the `REDUNDANT` row format.
- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.
- `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, [InnoDB](#) issues a warning and assumes `ROW_FORMAT=DYNAMIC`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, which is the default, [InnoDB](#) returns an error.
- For additional information about [InnoDB](#) row formats, see [Section 15.10, “InnoDB Row Formats”](#).

For [MyISAM](#) tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 16.2.3, “MyISAM Table Storage Formats”](#).

For [NDB](#) tables, the default `ROW_FORMAT` is `DYNAMIC`.

- `STATS_AUTO_RECALC`

Specifies whether to automatically recalculate [persistent statistics](#) for an [InnoDB](#) table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see [Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_PERSISTENT`

Specifies whether to enable [persistent statistics](#) for an [InnoDB](#) table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see [Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_SAMPLE_PAGES`

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. For more information, see [Section 15.8.10.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `TABLESPACE`

The `TABLESPACE` clause can be used to create a table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

```
CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name
```

The general tablespace that you specify must exist prior to using the `TABLESPACE` clause. For information about general tablespaces, see [Section 15.6.3.3, “General Tablespaces”](#).

The *tablespace_name* is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with “innodb_” are reserved for special use.

To create a table in the system tablespace, specify `innodb_system` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system
```

Using `TABLESPACE [=] innodb_system`, you can place a table of any uncompressed row format in the system tablespace regardless of the `innodb_file_per_table` setting. For example, you can add a table with `ROW_FORMAT=DYNAMIC` to the system tablespace using `TABLESPACE [=] innodb_system`.

To create a table in a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

Note

If `innodb_file_per_table` is enabled, you need not specify `TABLESPACE=innodb_file_per_table` to create an [InnoDB](#) file-per-table tablespace. [InnoDB](#) tables are created in file-per-table tablespaces by default when `innodb_file_per_table` is enabled.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` clause. As of MySQL 8.0.21, the directory specified in a `DATA DIRECTORY` clause must be known to [InnoDB](#). For more information, see [Using the DATA DIRECTORY Clause](#).

Note

Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is

deprecated as of MySQL 8.0.13 and will be removed in a future version of MySQL.

The `STORAGE` table option is employed only with `NDB` tables. `STORAGE` determines the type of storage used (disk or memory), and can be either `DISK` or `MEMORY`.

`TABLESPACE ... STORAGE DISK` assigns a table to an NDB Cluster Disk Data tablespace. The tablespace must already have been created using `CREATE TABLESPACE`. See [Section 22.5.10, “NDB Cluster Disk Data Tables”](#), for more information.

Important

A `STORAGE` clause cannot be used in a `CREATE TABLE` statement without a `TABLESPACE` clause.

- `UNION`

Used to access a collection of identical `MyISAM` tables as one. This works only with `MERGE` tables. See [Section 16.7, “The MERGE Storage Engine”](#).

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a `MERGE` table.

Note

Formerly, all tables used had to be in the same database as the `MERGE` table itself. This restriction no longer applies.

Table Partitioning

`partition_options` can be used to control partitioning of the table created with `CREATE TABLE`.

Not all options shown in the syntax for `partition_options` at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 23, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 13.1.9, “ALTER TABLE Statement”](#). For more detailed descriptions and examples, see [Section 23.3, “Partition Management”](#).

- `PARTITION BY`

If used, a `partition_options` clause begins with `PARTITION BY`. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to `num`, where `num` is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

Note

The expression (`expr`) used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

- `HASH(expr)`

Hashes one or more columns to create a key for placing and locating rows. `expr` is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

`PARTITION BY HASH` uses the remainder of *expr* divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 23.2.4, “HASH Partitioning”](#).

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see [Section 23.2.4.1, “LINEAR HASH Partitioning”](#).

- `KEY(column_list)`

This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The *column_list* argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY KEY(col3)
PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see [Section 23.2.4.1, “LINEAR HASH Partitioning”](#), and [Section 23.2.5, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR KEY(col3)
PARTITIONS 5;
```

The `ALGORITHM={1 | 2}` option is supported with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see [Section 13.1.9.1, “ALTER TABLE Partition Operations”](#).

`mysqldump` in MySQL 5.7 (and later) writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50611 ALGORITHM = 1 */ /*!50100 ( )
PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.7 server where you use tables that are partitioned or subpartitioned by `KEY` into a MySQL 5.6 server previous to version 5.6.11, be sure to consult [Changes in MySQL 5.6](#), before proceeding. (The information found there also applies if you are loading a dump containing `KEY` partitioned or subpartitioned tables made from a MySQL 5.7—actually 5.6.11 or later—server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is

always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- `RANGE(expr)`

In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

Note

For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 8.0, you can overcome this limitation in a table that is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

Partition Number:	Years Range:
0	1990 and earlier
1	1991 to 1994
2	1995 to 1998
3	1999 to 2002
4	2003 to 2005
5	2006 and later

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- `RANGE COLUMNS(column_list)`

This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND`

`b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...`. You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (
  a INT NOT NULL,
  b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (10,5),
  PARTITION p1 VALUES LESS THAN (20,10),
  PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
  PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
  PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see [Section 23.2.1, “RANGE Partitioning”](#), and [Section 23.4, “Partition Pruning”](#).

- `LIST(expr)`

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

`VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
```

```
);
```

When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

Note

For tables partitioned by `LIST`, the value list used with `VALUES IN` must consist of integer values only. In MySQL 8.0, you can overcome this limitation using partitioning by `LIST COLUMNS`, which is described later in this section.

- `LIST COLUMNS(column_list)`

This variant on `LIST` facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as `WHERE a = 5 AND b = 5` or `WHERE a = 1 AND b = 10 AND c = 5`). It enables you to specify values in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES IN (value_list)` partition definition clause.

The rules governing regarding data types for the column list used in `LIST COLUMNS(column_list)` and the value list used in `VALUES IN(value_list)` are the same as those for the column list used in `RANGE COLUMNS(column_list)` and the value list used in `VALUES LESS THAN(value_list)`, respectively, except that in the `VALUES IN` clause, `MAXVALUE` is not permitted, and you may use `NULL`.

There is one important difference between the list of values used for `VALUES IN` with `PARTITION BY LIST COLUMNS` as opposed to when it is used with `PARTITION BY LIST`. When used with `PARTITION BY LIST COLUMNS`, each element in the `VALUES IN` clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the `COLUMNS` clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the `column_list` and in the elements making up the `value_list` is 16.

The table defined by the following `CREATE TABLE` statement provides an example of a table using `LIST COLUMNS` partitioning:

```
CREATE TABLE lc (
  a INT NULL,
  b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
  PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- `PARTITIONS num`

The number of partitions may optionally be specified with a `PARTITIONS num` clause, where `num` is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, `num` must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

Note

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- `SUBPARTITION BY`

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- Rigorous checking of the value used in `PARTITIONS` or `SUBPARTITIONS` clauses is applied and this value must adhere to the following rules:
 - The value must be a positive, nonzero integer.
 - No leading zeros are permitted.
 - The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not permitted, even though `0.2E+01` evaluates to `2`. (Bug #15890)

- `partition_definition`

Each partition may be individually defined using a `partition_definition` clause. The individual parts making up this clause are as follows:

- `PARTITION partition_name`

Specifies a logical name for the partition.

- `VALUES`

For range partitioning, each partition must include a `VALUES LESS THAN` clause; for list partitioning, you must specify a `VALUES IN` clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 23, Partitioning](#), for syntax examples.

- `[STORAGE] ENGINE`

MySQL accepts a `[STORAGE] ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this option can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or

subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL`.

- `COMMENT`

An optional `COMMENT` clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

- `DATA DIRECTORY` and `INDEX DIRECTORY`

`DATA DIRECTORY` and `INDEX DIRECTORY` may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the `data_dir` and the `index_dir` must be absolute system path names.

As of MySQL 8.0.21, the directory specified in a `DATA DIRECTORY` clause must be known to `InnoDB`. For more information, see [Using the DATA DIRECTORY Clause](#).

You must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` partition option.

Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
    DATA DIRECTORY = '/var/appdata/97/data'
    INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2002 VALUES IN (1998, 2002, 2006)
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

`DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's `table_option` clause as used for `MyISAM` tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect.

- `MAX_ROWS` and `MIN_ROWS`

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive

integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- **TABLESPACE**

May be used to designate an [InnoDB](#) file-per-table tablespace for the partition by specifying `TABLESPACE `innodb_file_per_table``. All partitions must belong to the same storage engine.

Placing [InnoDB](#) table partitions in shared [InnoDB](#) tablespaces is not supported. Shared tablespaces include the [InnoDB](#) system tablespace and general tablespaces.

- *subpartition_definition*

The partition definition may optionally contain one or more *subpartition_definition* clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where *name* is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See [Section 23.2.6, “Subpartitioning”](#).

Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

```
CREATE TABLE t1 (
  s1 INT,
  s2 INT AS (EXP(s1)) STORED
)
PARTITION BY LIST (s2) (
  PARTITION p1 VALUES IN (1)
);
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see [Section 23.6.3, “Partitioning Limitations Relating to Functions”](#)). The preceding example demonstrates this technique: `EXP()` cannot be used directly in the `PARTITION BY` clause, but a generated column defined using `EXP()` is permitted.

13.1.20.1 Files Created by CREATE TABLE

For an [InnoDB](#) table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in a [.ibd file](#) in the database directory. When an [InnoDB](#) table is created in the system tablespace, table data and indexes are stored in the `ibdata*` files that represent the system tablespace. The `innodb_file_per_table` option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The `TABLESPACE` option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the `innodb_file_per_table` setting.

For [MyISAM](#) tables, the storage engine creates data and index files. Thus, for each [MyISAM](#) table *tbl_name*, there are two disk files.

File	Purpose
<i>tbl_name</i> .MYD	Data file
<i>tbl_name</i> .MYI	Index file

[Chapter 16, Alternative Storage Engines](#), describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.4, “Mapping of Identifiers to File Names”](#).

13.1.20.2 CREATE TEMPORARY TABLE Statement

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only within the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-`TEMPORARY` table of the same name. (The existing table is hidden until the temporary table is dropped.)

InnoDB does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns an error if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The `innodb_file_per-table` option does not affect the creation of InnoDB temporary tables.

`CREATE TABLE` causes an implicit commit, except when used with the `TEMPORARY` keyword. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

`TEMPORARY` tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any `TEMPORARY` tables created within that database.

To create a temporary table, you must have the `CREATE TEMPORARY TABLES` privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` privilege but is able to execute a definer-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

You cannot use `CREATE TEMPORARY TABLE ... LIKE` to create an empty table based on the definition of a table that resides in the `mysql` tablespace, InnoDB system tablespace (`innodb_system`), or a general tablespace. The tablespace definition for such a table includes a `TABLESPACE` attribute that defines the tablespace where the table resides, and the aforementioned tablespaces do not support temporary tables. To create a temporary table based on the definition of such a table, use this syntax instead:

```
CREATE TEMPORARY TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

Note

Support for `TABLESPACE = innodb_file_per_table` and `TABLESPACE = innodb_temporary` clauses with `CREATE TEMPORARY TABLE` is deprecated as of MySQL 8.0.13 and will be removed in a future version of MySQL.

13.1.20.3 CREATE TABLE ... LIKE Statement

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

Important

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

CREATE TABLE ... LIKE makes the same checks as **CREATE TABLE**. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

For **CREATE TABLE ... LIKE**, the destination table preserves generated column information from the original table.

For **CREATE TABLE ... LIKE**, the destination table preserves expression default values from the original table.

For **CREATE TABLE ... LIKE**, the destination table preserves **CHECK** constraints from the original table, except that all the constraint names are generated.

CREATE TABLE ... LIKE does not preserve any **DATA DIRECTORY** or **INDEX DIRECTORY** table options that were specified for the original table, or any foreign key definitions.

If the original table is a **TEMPORARY** table, **CREATE TABLE ... LIKE** does not preserve **TEMPORARY**. To create a **TEMPORARY** destination table, use **CREATE TEMPORARY TABLE ... LIKE**.

Tables created in the **mysql** tablespace, the **InnoDB** system tablespace (**innodb_system**), or general tablespaces include a **TABLESPACE** attribute in the table definition, which defines the tablespace where the table resides. Due to a temporary regression, **CREATE TABLE ... LIKE** preserves the **TABLESPACE** attribute and creates the table in the defined tablespace regardless of the **innodb_file_per_table** setting. To avoid the **TABLESPACE** attribute when creating an empty table based on the definition of such a table, use this syntax instead:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

CREATE TABLE ... LIKE operations apply all **ENGINE_ATTRIBUTE** and **SECONDARY_ENGINE_ATTRIBUTE** values to the new table.

13.1.20.4 CREATE TABLE ... SELECT Statement

You can create one table from another by adding a **SELECT** statement at the end of the **CREATE TABLE** statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the **SELECT**. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
->     PRIMARY KEY (a), KEY(b))
->     ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a **MyISAM** table with three columns, **a**, **b**, and **c**. The **ENGINE** option is part of the **CREATE TABLE** statement, and should not be used following the **SELECT**; this would result in a syntax error. The same is true for other **CREATE TABLE** options such as **CHARSET**.

Notice that the columns from the **SELECT** statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n  |
+----+
| 1  |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM bar;
+-----+
| m     |
+-----+
```

```

| m | n |
+---+---+
| NULL | 1 |
+---+---+
1 row in set (0.00 sec)

```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.
